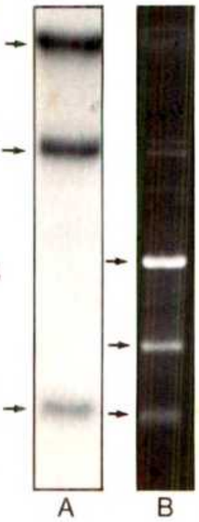
Promega's Riboprobe System...
...Easier Then Ever To Use

erformance Guaranteed and erifiable

Ve provide a positive control template vhich is specifically constructed to en- ure that you get good transcription eaction performance.

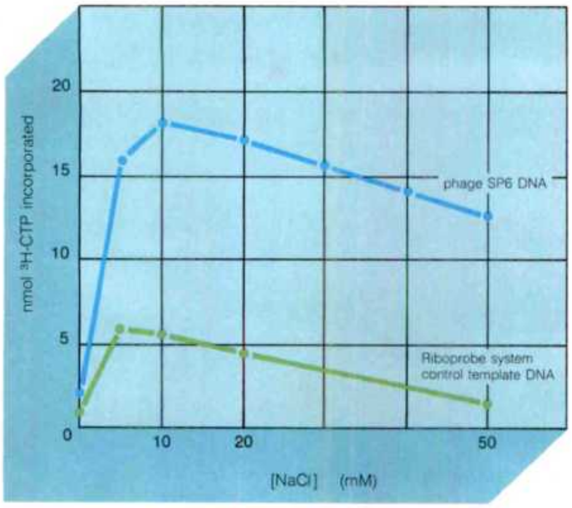
his mixture of Riboprobe system plas- nid constructs simultaneously synthe- izes three discrete transcripts: 0.225 kb, .557 kb, and 1.386 kb. The labeled anscription products are shown in el A.

lso, under nonlimiting synthesis condi- ons the amount of RNA synthesized is o high that detection of transcripts is ossible without radioisotopes (gel B).



New Reaction Conditions

romega provides up-to-date information on the best onditions for transcription reactions and for the subse- uent use of the RNA products made. For example, we ecently determined that the addition of 5-20 mM NaCl ncreases transcription product synthesis as much as fold. A salt curve analysis of transcription on two ifferent templates is presented below.



s we test and experiment with the Riboprobe system, ve are finding new applications and conditions for its ise all the time. Promega customers will receive all of is information as it becomes available.

Introducing Riboprobe™ *System II*

Minimizes Reaction Set Up Time

This product contains all the reagents (excluding radioisotopes) required for performing up to 50 efficient transcription reactions. The availability of these pretested and qualified reagents reduces your reaction set up time a great deal and helps assure consistent results:

- Riboprobe System RNA polymerase
- 20 μg pSP64 plasmid
- 20 μg pSP65 plasmid
- 10 μg Riboprobe system positive control transcription template
- RNasin® ribonuclease inhibitor
- lot qualified solutions of all 4 cold ribonucleotides
- transcription optimized 5X buffer
- 100mM DTT

Other Benefits Of Using Riboprobe™ *System II:*

Guaranteed performance
With the purchase of our *System II,* we provide all the test data obtained on the lot of reagents you recei You can quickly verify the system's effectiveness yourself.

Cost effectiveness
This system is very cost effective. When you add up the real cost for your lab to buy and test all the reagents involved, it is actually cheaper to buy our Riboprobe™ *System II.*

Proven protocols
With our system you will receive up-to-date, detailed protocols including:

- plasmid preparation procedures
- transcription reaction conditions
- blot hybridization techniques

Components also available separately
All components of the Riboprobe *System II* are available separately, as needed, including Riboprob system polymerase and RNasin® ribonuclease inhibitor.

Promega Biotec

Circle No.22 on Reader Service Card

f you have already received an informational packet on the Riboprobe system, but got it before July, 1984, ou can call us again to get a copy of the updated applications information and new product configura- ons described above.

Riboprobe™

Gene Analysis System

- ☐ **May make nick translation obsolete.**
- ☐ **Increases Northern/Southern blot sensitivity up to 10 fold.**
  (and/or reduces exposure times up to 10 fold)
- ☐ **Eliminates the need to isolate probes from gels.**
- ☐ **Increases *in situ* hybridization sensitivity.**
- ☐ **Eliminates the need to end label probes in many applications.**

Current research confirms that RNA can be used successfully for gene probing, providing greater sensitivity than can be achieved with similar DNA probes (see our technical information sheets for references). The **Riboprobe**™ gene analysis system offers a convenient vector/enzyme system for the preparation of microgram quantities of high specific activity single-stranded RNA's. These RNA's are suitable for use as probes, as RNA processing substrates, and for other applications where large amounts of hot specific RNA's or enhanced probing sensitivity is required.

The **Riboprobe** system consists of: **1)** highly purified, RNase-free bacteriophage SP6 RNA polymerase, **2)** the latest **Riboprobe** system SP6 vectors (pSP64, pSP65) as developed by Melton, Krieg, and Green, *et al.* (see technical information sheets for references), and **3)** a **Riboprobe** system RNA marker template for use as a positive control.

With the **Riboprobe** system, simply ligate your DNA into one of the **Riboprobe** system plasmids, prepare a recombinant plasmid by standard plasmid propagation and purification techniques, linearize the recombinant plasmid with the appropriate restriction enzyme, add the **Riboprobe** system polymerase with labelled ribonucleotides, and incubate the reaction.

The **Riboprobe** system does the rest. It is exceedingly efficient and, depending on conditions, can synthesize up to 10 μg of RNA from 1 μg of plasmid template. **The use of this RNA will improve or replace many important analytical procedures in molecular biology.**

Circle No.21 on Reader Service Card.

Promega Biotec

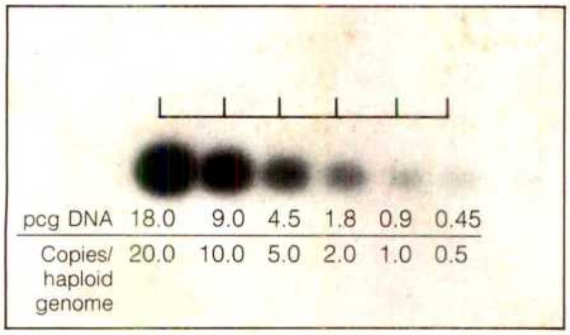
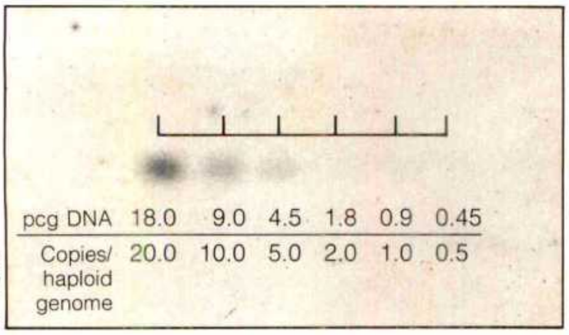
Routine Detection of Single Copy Genes with RNA Probes

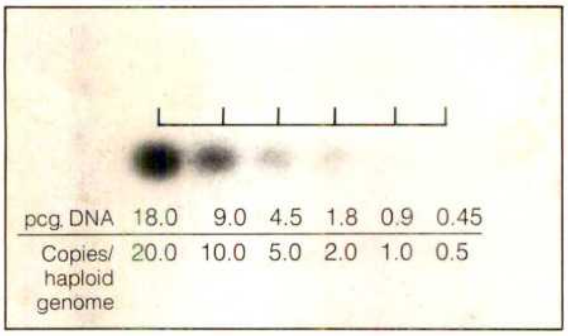
Side by side comparison demonstrates superior performance.



RNA Probe



Nick Translated Probe

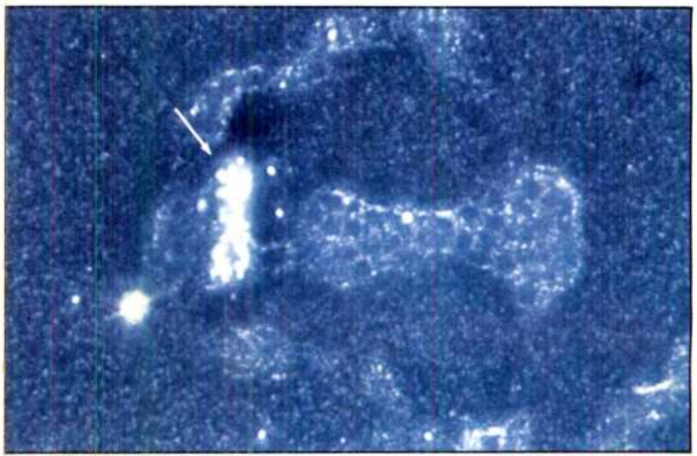


M-13 Probe

Riboprobe system synthesized RNA probes were directly compared with similarly labeled nick translated DNA probes and primer extended M-13 probes. Significant sensitivity increases (up to 10 fold in favor of the RNA probe) were observed in detection of relevant sequences.

Under comparable conditions, the Riboprobe system detected 0.45 picograms of the target sequence, the nick translated DNA probe shows 4.5 picograms and the M-13 probe 1.8 picograms. (Data provided by E. Schenborn and J. Mitchen, University of Wisconsin). Standardized for the number of gene copies detected, the Riboprobe system synthesized probe easily detects 0.5 copies/haploid genome, demonstrating its effectiveness for analyzing single copy genes.

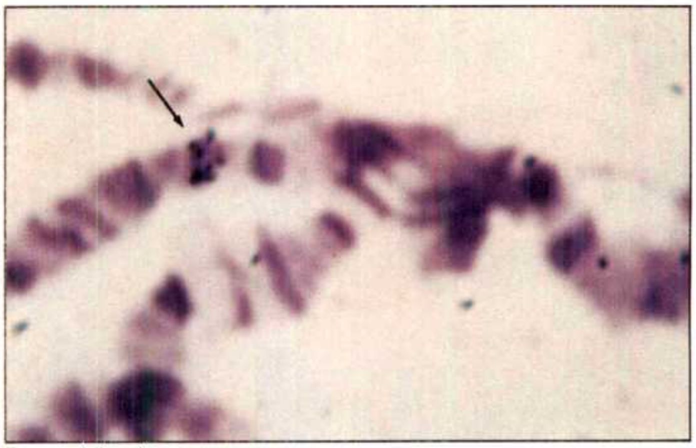
In situ hybridizations: Results demonstrate high signal to noise ratios and efficient detection of target sequences.



Sea Urchin tissue

Sea urchin plutei tissue sections were analyzed by *in situ* hybridization using an RNA probe specific for muscle actin message (Schott *et al.*, 1984). A high signal is detected in the few cells synthesizing the actin message (see arrow). The absence of noise over cells not expressing the gene demonstrates the specificity of the system (Data provided by L. Angerer, University of Rochester).

Sensitivity is increased at least eight fold when the detection capabilities of these single stranded RNA probes are compared with those of comparable double stranded probes. A detailed technical information sheet on *in situ* hybridization is available on request from Promega Biotec.



Drosophila chromosome

Drosophila salivary gland chromosomes were analyzed for the location of a cloned drosophila genomic DNA fragment. (Data provided by K. Loughney and B. Ganetzky, University of Wisconsin). Specific signals were detected after the short exposure time of 5-7 days (see arrow). The results indicate very high signal to noise ratios.

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

Close your eyes.

Imagine you're creating a weekly current awareness service for scientists and scholars—one that would alert you to just those articles you were interested in. You think to yourself, this is a good idea...but impossible.

Now open your eyes. Such a service is available right now. It's called ASCA®. ASCA is custom-designed ...for each individual...anywhere in the world...in any discipline. And your individualized ASCA reports can cost as little as $3.00 per week. Intrigued? Want more information? Fill out the coupon and mail it. You'll be glad you did.

Let ASCA Open Your Eyes.

☐ Send me more information about ASCA®.

The best counts with Amersham

Save time! Book yourself a large library... use Amersham's λ *in vitro* packaging kits.

- **High efficiency** – routinely $>2 \times 10^8$ pfu/µg λ DNA (λcI857 *Sam* 7)
- **Low backgrounds** – $<1 \times 10^2$ plaques per reaction (0·00005% of expected phage yield with λ DNA)
- **Reliable** – rigorously tested to ensure quality
- **Convenient** – simple protocol provided with ready-to-use aliquots
- **Flexible** – a choice of 3 pack sizes

3-reaction kit	code N.334Y
5-reaction kit	code N.334Z
10-reaction kit	code N.334L

- **Also available** – the complete range for construction of genomic libraries, including:
  - λ vectors and arms
  - cosmid vectors and arms
  - restriction endonucleases
  - modifying enzymes

Amersham – unparalleled commitment to your research

- Atmospheric toluene degradation
- Back-front in *Drosophila* embryos
- X and Y chromosomal similarity
- Defective *ras* gene activity
- Polyoma and papilloma similarities
- Evolution of ratites

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

THERE'S NO OTHER PROTEIN A LIKE ASORB™

The charts tell it all.

First, look at purity. Note that only one competitive brand even approaches Asorb.™

Then compare the prices.* That "pure-looking" competitor charges you almost three times what we do. And look how high the others are.

By any comparison, the clear winner is Asorb. Created by the maker of IgGsorb.®

Asorb is stable as a lyophilized powder for two years at 4°C. We're ready to ship at 24 hours' notice.

So call us today.

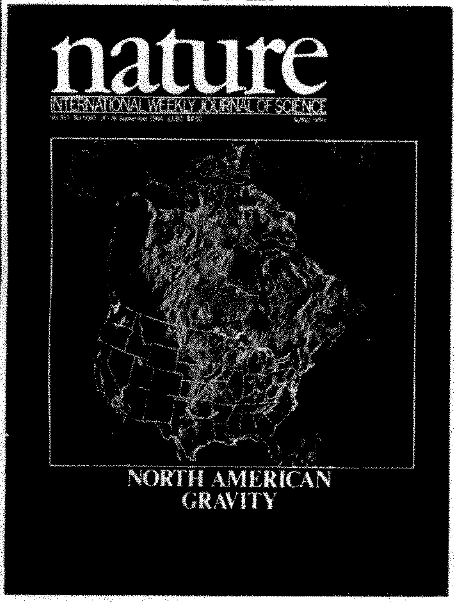
NATURE VOL. 311 20 SEPTEMBER 1984

COVER



A Bouguer anomaly image for North America generated using 750,000 anomalies computed from ground readings and interpolations between stations. The processed data were converted to shaded relief form and overlain with colour-coded anomaly values from purple (−343 in mGal) to pink (316 mGal). A simulated sun was placed at 20° above the western horizon. The image is in a Lambert equal area projection, centred at 52° N latitude, 90° W longitude. See p.241. (Data Defense Mapping Agency Aerospace Center, St Louis, and the Department of Energy, Mines and Resources, Canada.)

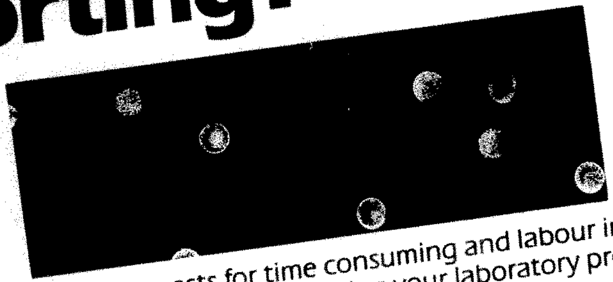
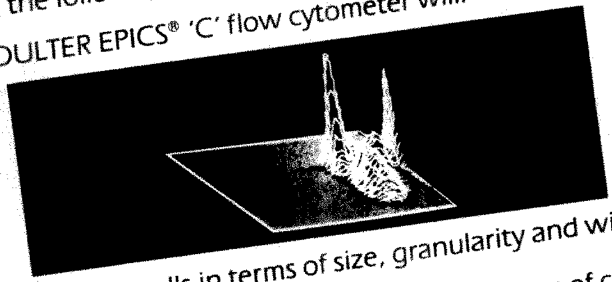
Do your fluorescent problems need sorting?



Increasing requests for time consuming and labour intensive fluorescent analysis may be causing your laboratory problems.

If so, the following news should help:

The COULTER EPICS® 'C' flow cytometer will:—



- Characterise cells in terms of size, granularity and with fluorescent probes.
- Carry out high speed analysis on large numbers of cells.
- Sort populations of interest for positive identification and further examination.

It will do this:—

Quickly — on up to 10,000 cells per second

Simply — with user definable 'profiles'

Economically — low capital outlay and running costs

Epics® C

Automatic cell analyser and sorter at an 'analyser only' price. Let Coulter help to sort your problem!

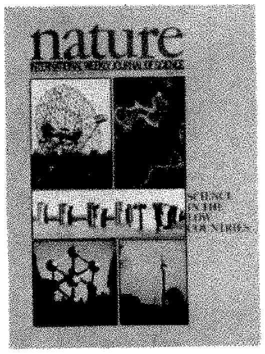
CONTENTS

SCIENCE IN THE LOW COUNTRIES



- *Will the policy of "concentrating" the universities in Holland and Belgium create more problems than it solves?*
- *Is Belgian science stagnating?*
- *What would be the effect of increased government control over Dutch research policy?*

These and other questions are examined in *Nature*'s special supplement on Science in the Low Countries.
Extra copies of this issue are available now from the address given below.

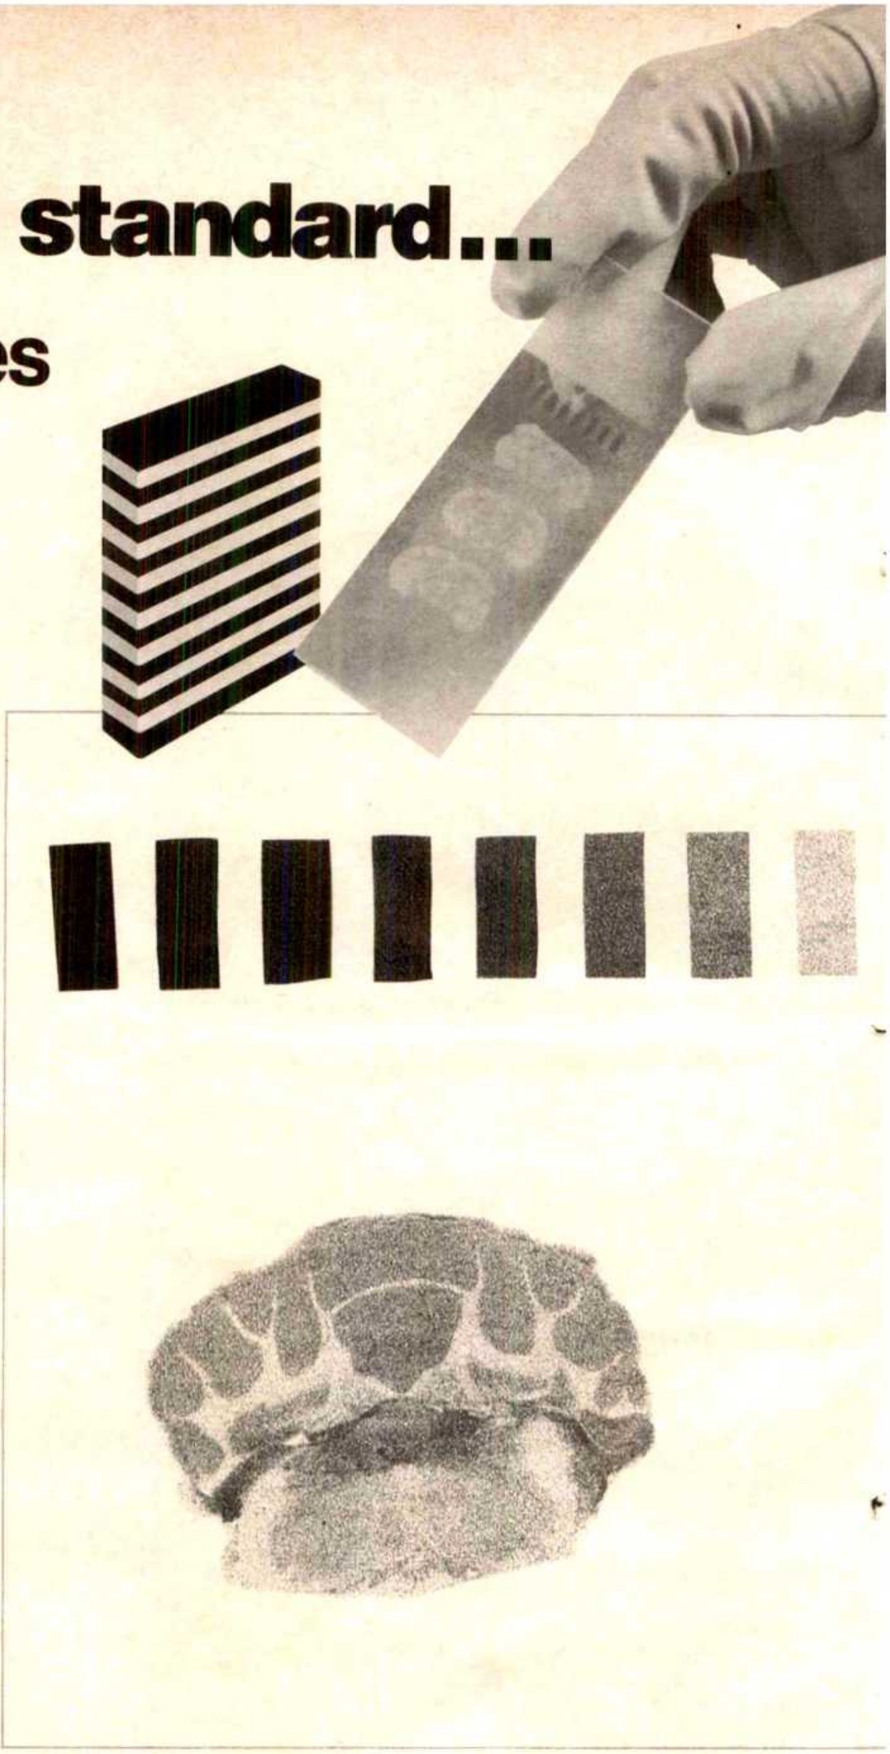
Setting the standard...

$[^3H]$ Micro-scales



Easy, accurate way to quantify tritium distribution by autoradiography

Compare $[^3H]$ Micro-scales with your current quantification procedure for ease of use, speed, dependable uniformity and accuracy. Micro-scales from Amersham set the standard by which all others will be measured.

That's because each Micro-scale block consists of eight layers of tritiated polymer, arranged in order of increasing specific activity—from 3 to 110nCi/mg—and separated by inactive layers. Using a standard microtome, the block can be sliced into hundreds of sections . . . each sized to fit on a standard microscope slide along with tissue sections. Then, when an autoradiogram is exposed and developed, tissue radioactivity levels can be calibrated directly against the Micro-scale.

Because hundreds of slices can be cut from each Micro-scale block, the cost per calibration is very low. And, potential applications extend to anyone currently performing $[^3H]$ autoradiography of cells, tissues or other substrates. For details, write or call for literature on $[^3H]$ Micro-scales. The new standard for autoradiography.

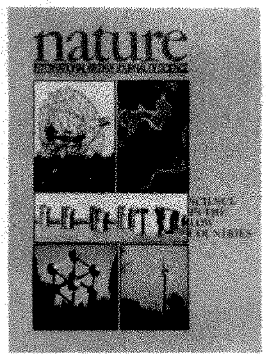
CONTENTS

SCIENCE IN THE LOW COUNTRIES



- *Will the policy of "concentrating" the universities in Holland and Belgium create more problems than it solves?*
- *Is Belgian science stagnating?*
- *What would be the effect of increased government control over Dutch research policy?*

These and other questions are examined in *Nature*'s special supplement on Science in the Low Countries.
Extra copies of this issue are available now from the address given below.

NATURE CLASSIFIED

Professional appointments — Research posts — Studentships — Fellowships — Conferences — Courses — Seminars — Symposia: Back pages

Next week in *Nature*:

- Cell-cycle oncogenes
- Oncogene phosphorylation
- Neuronal replacement
- Giant synaptosomes
- Neurone classification by antibodies
- Neostriatal patch/matrix interplay
- Parkinsonism and monoamine oxidase
- Deep-sea helium-3
- Noiseless NMR
- Boltzmann's ultraviolet conjecture
- Stress in tectonic plates
- Cellular automata

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

POURQUOI ?

L'Association nationale des Docteurs ès-Sciences (ANDES) a été créée en 1970. Reconnue d'utilité publique en 1975, elle est une association pluridisciplinaire et multiprofessionnelle servant de ralliement à des scientifiques très diversifiés dans leur devenir post-doctoral. Elle a pour buts essentiels :

- **d'agir en faveur de la diffusion de la culture scientifique et de l'expansion de la Recherche,**
- **d'affirmer le rôle des scientifiques dans la France et le monde de demain, répartis dans le monde entier,**
- **d'associer, dans une structure de dialogue, les Docteurs ès-Sciences de l'Université, des Organismes de recherche, de l'Administration et de l'Industrie,**
- **d'accroître la participation des scientifiques à la vie de la Nation et de les aider à contribuer au développement des activités socio-économiques qui transforment la société,**
- **de développer les contacts et l'information entre l'Université et l'Industrie,**
- **d'aider les Docteurs ès-Sciences dans la recherche d'un emploi et de réfléchir, d'une manière générale, au problème de l'emploi et des carrières des Docteurs ès-Sciences.**

COMMENT ?

- par la diffusion d'un Bulletin de liaison, ANDES-Informations, qui tient informés les membres de l'Association de tout texte administratif les concernant,
- par la publication de dossiers, de documents ou libres blancs destinés à la réflexion de la communauté des Docteurs ès-Sciences sur les problèmes d'actualité,
- par un annuaire informatisé bisannuel qui contient à ce jour 2530 noms de Docteurs ès-Sciences français ou étrangers, formés en France par la Recherche, donc francophones. Répartis dans le monde entier, ils sont universitaires, chercheurs, agents économiques, industriels, coopérants, membres de services diplomatiques ou d'organisations internationales. Un classement par disciplines scientifiques permet de faire appel à leur compétence pour le traitement de problèmes scientifiques ou techniques spécifiques,
- par des contacts suivis avec le (ou les) ministères chargé de la Recherche et de l'Industrie, les ministères de l'Éducation nationale, de la Formation professionnelle, du Travail et des Relations extérieures, en vue d'une information constructive et réciproque, condition du maintien élevé du niveau du Doctorat français,
- par des conférences et des tables rondes organisées périodiquement sur des sujets divers intéressant la vie de l'ANDES, les activités et le rôle des Docteurs ès-Sciences dans l'économie nationale et internationale, et les grands thèmes liés à la prospective scientifique,
- par l'organisation de rencontres entre Docteurs ès-Sciences de l'Industrie, de l'Université et des grands organismes publics.

DOCUMENTS DISPONIBLES sur demande au siège de l'ANDES, règlement à la commande par chèque bancaire ou postal à l'ordre de l'ANDES (CCP PARIS 7692-77 B).

1. **Étude sommaire comparative des diplômes universitaires scientifiques dans divers pays industrialisés,** 53 pages, Janvier 1980, 20 FF plus port (— de 250 g).
2. **Annuaire des Docteurs ès-Sciences** (n° ISSN 0761-1587), 5e édition, Mars 1984, 120 FF plus port (+ de 500 g). 2530 noms en 4 listes : alphabétique, géographique, professionnelle, scientifique.
3. **Document sur les Bourses ou contrats de recherche pour français ou étrangers,** Numéro spécial 32 du Bulletin d'ANDES-Informations, 18 pages, Juin 1984, 30 FF plus port (— de 100 g).
4. **Minicatalogue des Thèses de Doctorat ès-Sciences,** 108 titres, 80 pages, Juillet 1984, 30 FF plus port (— de 250 g).

CONDITIONS D'ADHÉSION : Membres ordinaires **170 FF** (demi-tarif pour retraité, conjoint et docteurs ès-sciences depuis moins de 3 ans) - Membres bienfaiteurs **850 FF** - Membres à vie **2 040 FF.**

BULLETIN D'ADHÉSION donne droit à l'envoi gratuit de l'Annuaire en cours, et des Bulletins d'ANDES-Informations récents - l'adresser au siège de l'ANDES, 16, rue Claude-Bernard, 75231 Paris Cedex 05, France. Les documents à remplir pour figurer dans le fichier seront envoyés par retour.

RECOVER SAMPLES FROM GELS AND GRADIENTS.

CONCENTRATE SMALL SAMPLES FAST.

Concentrate and separate samples from non-ionic media such as polyacrylamide gels or density gradient sugar solutions. You can use an Isco concentrator for proteins, nucleic acids, certain whole cells and fragments, or any other water soluble macromolecule larger than 3500 MW and having electrophoretic mobility

The Isco concentrator gives you 50-fold concentration of up to sixteen 10 ml samples in 90 minutes or less. To learn more, write or phone toll-free **[800]228-4250.**

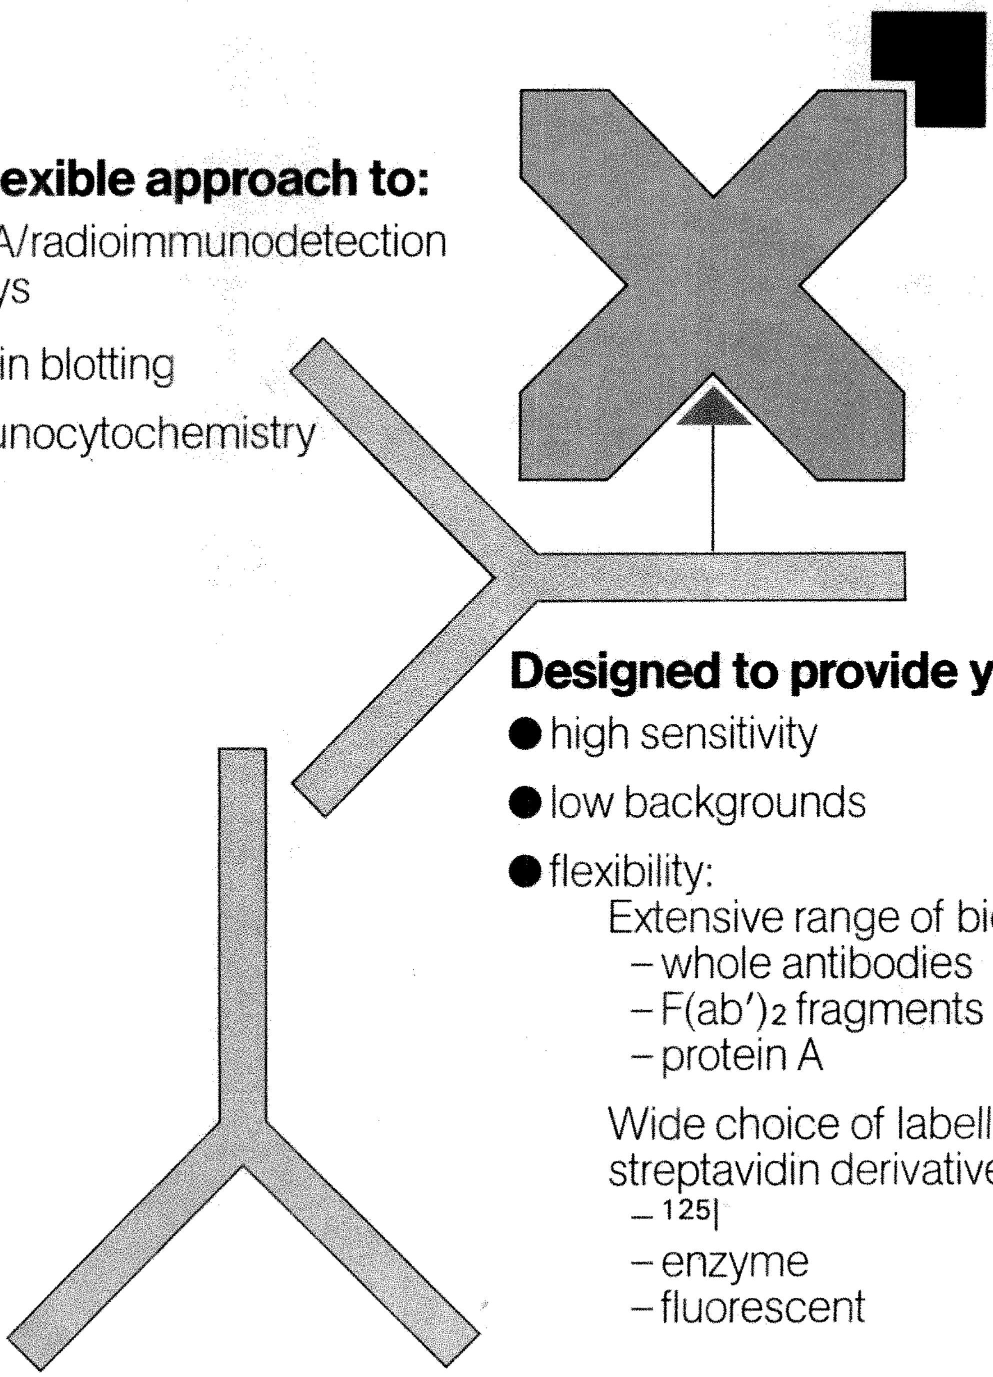
New biotin-streptavidin systems from Amersham



Your flexible approach to:

- ELISA/radioimmunodetection assays
- protein blotting
- immunocytochemistry

Designed to provide you with:

- high sensitivity
- low backgrounds
- flexibility:
  Extensive range of biotinylated
  - whole antibodies
  - $F(ab')_2$ fragments
  - protein A

  Wide choice of labelled streptavidin derivatives
  - $^{125}\mathrm{I}$
  - enzyme
  - fluorescent

For more details of this high performance detection system, please contact our Research Products Technical Service department or your local representative.

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

CONTENTS

● HOW BRITAIN RUNS ITS SCIENCE

The new edition is available now. Nature's successful wallchart has been updated to take account of the changes in structure and personnel since the previous edition was published in 1981.
It includes the ministerial and other changes which followed the 1983 British General Election and provides a comprehensive survey of the administration of British science. Designed as a fold-out sheet, it can be carried easily to meetings or hung as a poster for permanent reference.

The new wallchart is available at £3.50 or US$7.95 from Nature's offices in Basingstoke or New York.

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

BRITAIN AFTER NUCLEAR WAR

A NATIONAL BRIEFING ON THE 'NUCLEAR WINTER'
BY THREE OF THE WORLD S LEADING AUTHORITIES ON THE SUBJECT.

MOVEMENT DISORDERS – TREMOR

ed. Leslie J. Findley and Rudy Capildeo

This new volume provides the most comprehensive study of normal and pathological tremor currently available. It is interdisciplinary in its approach and contains contributions from all the leading researchers in this field, including C. D. Marsden, R. Young and K. E. Hagbarth. The 35 chapters are arranged under the broad headings: 1. General Aspects 2. Neurophysiology of Tremor 3. Essential Tremor 4. The Tremors of Parkinson's Disease 5. Cerebellar Tremor 6. Tremors in Peripheral Neuropathy 7. Tremulous and Tremor-Like Movements of the Eyes 8. Diverse Tremulous States.

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

Fermentation engineering tailored to your specifications

You get better results in laboratory and production scale fermentations by using equipment with incorporated know-how. And when this equipment is tailored to your special tasks, you'll be another step ahead. B. Braun offers both. With their expertise and pragmatic approach, B. Braun utilizes the latest technology to plan and set up your fermenter – meeting your requirements exactly. Try us.

RHODOPSIN IN ALGAL PHOTOTAXIS
IMMUNOLOGICAL TECHNIQUES
product review

Rhodopsin, a visual pigment ubiquitous in multicellular organisms, is also present in the unicellular alga *Chlamydomonas*. This supports the idea that visual pigments have a common ancient origin (see p.756, and News and Views p.702). Cover shows the related multicellular alga *Volvox carteri f. weismannia*. Each cell has a blue "eye" which reflects light; magenta is chloroplast fluorescence. (Photo: K.W. Foster and R. Birchem.)

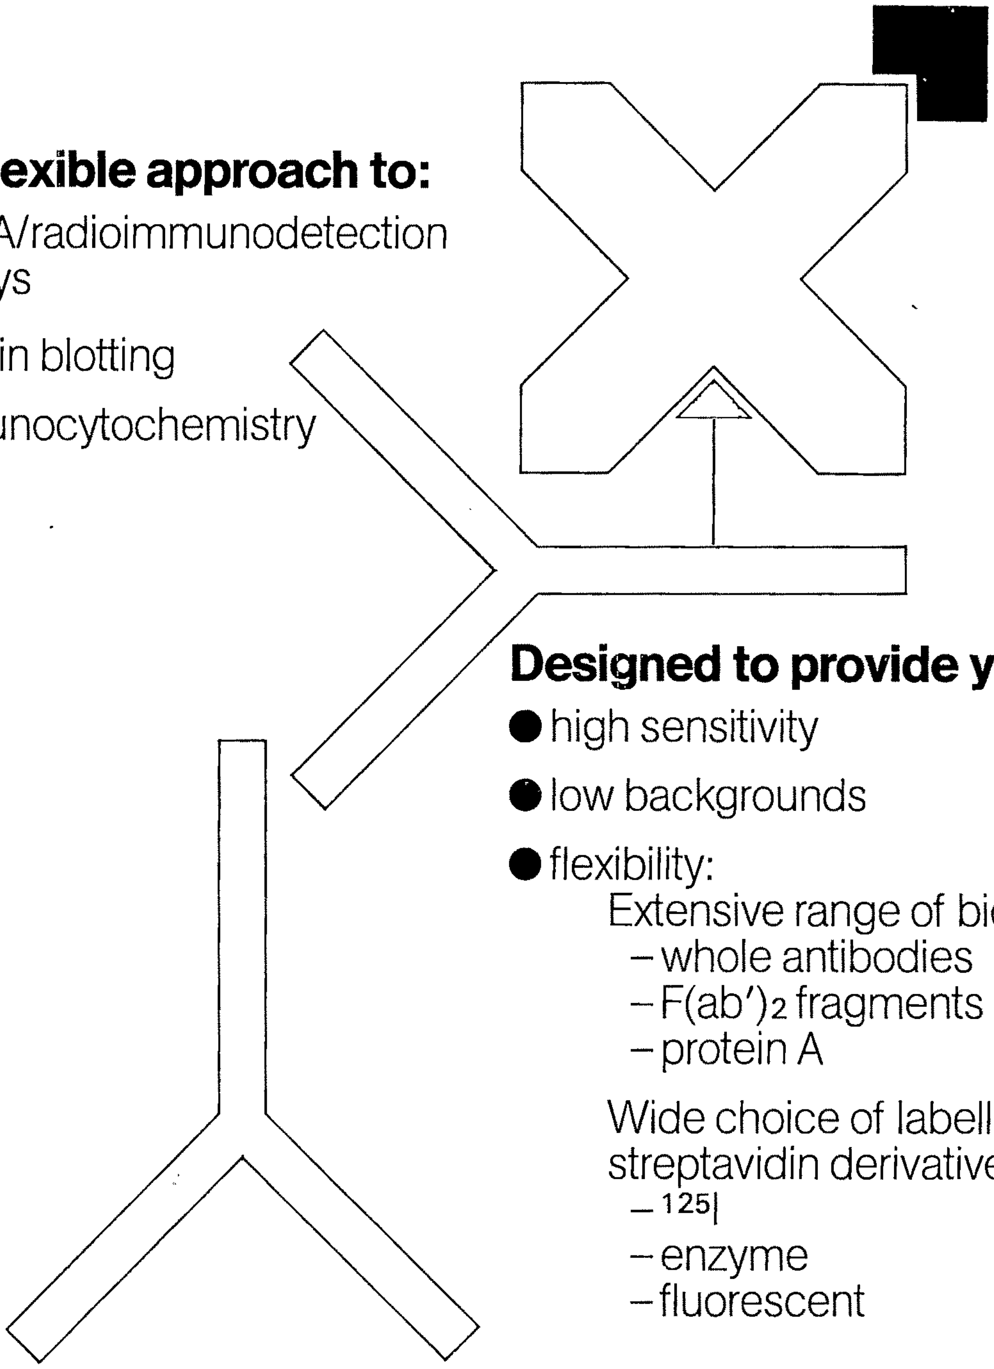
New biotin-streptavidin systems from Amersham



Your flexible approach to:

- ELISA/radioimmunodetection assays
- protein blotting
- immunocytochemistry

Designed to provide you with:

- high sensitivity
- low backgrounds
- flexibility:
  Extensive range of biotinylated
    - whole antibodies
    - F(ab')$_2$ fragments
    - protein A

  Wide choice of labelled streptavidin derivatives
    - ^{125}I
    - enzyme
    - fluorescent

For more details of this high performance detection system, please contact our Research Products Technical Service department or your local representative.

● HOW BRITAIN RUNS ITS SCIENCE

The latest edition is available now. Nature's successful wallchart has been updated to take account of the changes in structure and personnel since the previous edition was published in 1981.
It includes the ministerial and other changes which followed the 1983 British General Election and provides a comprehensive survey of the administration of British science.
Designed as a fold-out sheet, it can be carried easily to meetings or hung as a poster for permanent reference.

The wallchart is available at £3.50 or US$7.95 from Nature's offices in Basingstoke or New York.

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

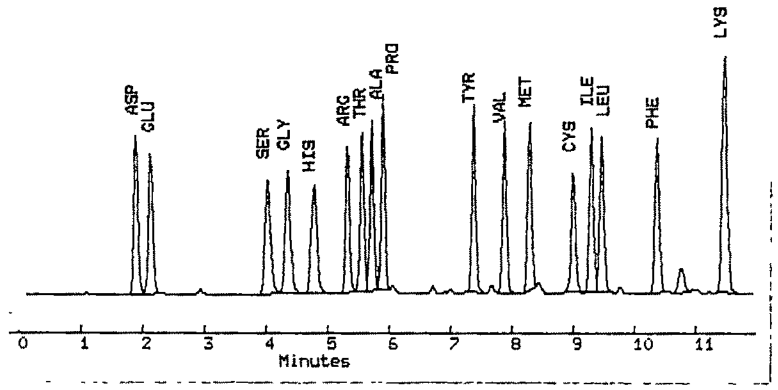
References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

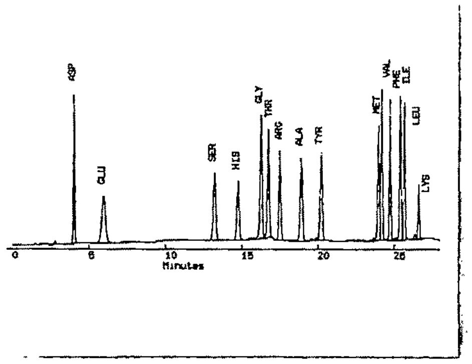
Waters™ HPLC Systems for Amino Acid Analysis.

Now analyze primary and secondary amino acids with one picomole sensitivity.

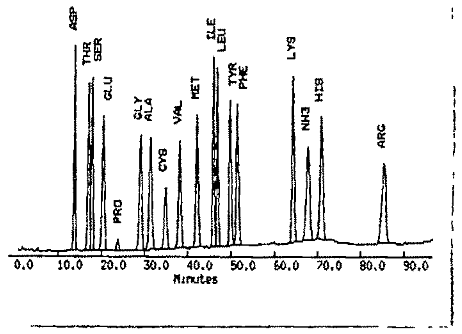


Introducing Waters high-speed PICO·TAG™ method. This innovative pre-column derivatization method is pre-packaged for guaranteed results. In 15 minutes, you can run a complete compositional analysis from as little as 100 nanograms of protein, with a detection limit of one picomole. Waters provides the complete methodology, plus reagents, buffers, column, Waters HPLC System and PICO·TAG Work Station.

With Waters Systems, choose the method that best meets your needs.



Waters AUTO·TAG™ OPA fully automated derivatization method. This exclusive method offers fully automated pre-column derivatization, separation and data reduction for high sensitivity analysis of primary amino acids. Perfect for process monitoring of amino acids in fermentation broths and cell cultures.



Classical Ion Exchange method with better quantitation. Waters improves this high resolution method with raw chromatographic data storage and re-integration capability for better quantitation, and full documentation of method, chromatography and integration.

More than offering just a choice of methodologies, Waters helps you get results.

For more information, contact Waters Life Science Dept., 34 Maple Street, Milford, MA 01757, 617-478-2000 (X 2665).

Poor show for aviation industry

This week's Farnborough show of the aircraft industry is not so much a trade fair as a reminder that the industry's chief product, civil air transport, is not as accessible or cheap as it should be.

THE English place-name Farnborough means two things — a research establishment (the Royal Aircraft Research Establishment) and an air show (mounted every other year on the establishment's private airfield by the Society of British Aircraft Constructors). Once, the air show was what the name suggests, an opportunity for the wider public to see and inspect the latest wonders of aviation — aircraft with six wings and then with two; aircraft with metal wings and enclosed cockpits; aircraft capable of carrying passengers; and so on. Now, as this week's show will have amply demonstrated, the biannual show is nothing of the kind. Most of the exhibitors are not plane-makers but would-be manufacturers of bits and pieces from which aircraft may eventually be assembled. Those who make navigation equipment, or who provide fast-food for airline passengers, may even turn out to have done enough business at this year's show to justify the cost of being present. But in spite of the ritual flying display by familiar flying machines, most of them military, the show should be, for most of those who attend it, a reminder that the aircraft business is in a mess. And that it will remain so unless drastic steps are taken towards reform.

The problems are mostly political, deriving from the way in which governments of most countries seek short-term gains from technology at the expense of the potential beneficiaries — ordinary people, either as air-travellers or as taxpayers. Since the days when biplanes were made robust enough reliably to cross the narrow strip of water between England and France during the First World War, the aircraft business has become thoroughly international in the particular sense that international travel has become habitual and largely beneficial. Families split by emigration half a century ago unexpectedly find themselves reunited. People who choose to work in two continents can do so. People bored with vacations at Morecambe or Martha's Vineyard can hope to swim off Marrakesh instead. Even though groups of malcontents occasionally seize civil aircraft and force them to fly to places not on their flight-plans, the general influence of civil air transport is rightly to be welcomed. The tragedy is that the benefits of this important technology would be even more widely shared if it were properly exploited.

Problems

There are three ingredients of the muddle afflicting aircraft technology, all of them familiar. The chief is the practice by which most governments connive at the distortion of the air travel market by subsidizing national airlines and then by seeking to minimize the costs of that malpractice by bartering the right to fly over international routes with other governments. Second is the argument, even by governments guiltless on the first count, that aircraft technology is so closely bound up with military security that self-sufficiency is essential. Finally, the cost of developing new flying machines has been allowed, by lax governments and extravagant manufacturers, to become so large that the cost of equipment — and the risks in making it — are needlessly great. This is how governments and manufacturers should set out to put this ramshackle industry in order.

The distortion in the market for air travel is sanctified by an international conference in Ottawa in 1944, in the heady days when people hoped the United Nations would replace chauvinism by international charity. For much of the past 40 years, the International Air Transport Authority (IATA) which was a direct result has functioned as a simple cartel, allowing airlines to fix the prices charged for tickets on international routes. The same experience, working on the principle that the slice of the lower atmosphere above each country is part of its sovereign territory, launched the iniquitous doctrine that governments should be required to negotiate bilaterally how many flights by which airlines there should be between one and the other. In most parts of the world, the result has been that prices have been too high and services too few. That there would be problems in the outright deregulation of international air transport is not denied. Maverick governments willing indefinitely to support their national airlines could easily drive into bankruptcy competing airlines enjoying reciprocal rights but organized commercially. It would simply be necessary to drive down fares. The short-term remedy is the scheme the British and Dutch Governments have imaginatively drawn up for deregulating traffic between London and Amsterdam — there is a low minimum fare, but restrictions on frequency and the onward destinations of passengers are abolished. Other governments should follow suit — and in Europe, the European Commission should prod them more vigorously. Further ahead, there is a crying need that all airlines should operate on near-commercial principles. In Europe, the best solution would be a European fund specially created to finance airline operations in the inevitable years of deficit — and an agreement that airlines that cannot survive prudent bankers' investigation should go to the wall.

Chauvinism

The chauvinism that runs through the aircraft manufacturing business with disastrous consequences must somehow be moderated. Outside the Soviet Union and China, there are only three practical suppliers of large civil aircraft (Boeing, McDonnell-Douglas and Airbus Industrie, the European consortium) and three manufacturers of large jet engines (Rolls-Royce, General Electric and Pratt and Whitney). This is probably as many as a thin market will support, yet these companies are increasingly under pressure to make deals with local manufacturers in the countries whose national airlines agree to buy their wares, sometimes to abate the purchase price, more often to acquire unfamiliar skills. In military aircraft, the consequences of chauvinism are even worse. The widespread practice, even among military allies, of manufacturing as much as possible of their service aircraft is a means of increasing the great cost of these machines, and of keeping together groups of workers which are already too large. The excuse is that indigenous technology and manufacturing capacity are strategic necessities, a particularly thin excuse when military planners say that future wars will be unpleasantly nasty but mercilessly short. The economic consequences of these arrangements are easily guessed. Modern aircraft are assembled from bits and pieces themselves manufactured by companies which are smaller than they need be, and often too small to be fully skilled. Flying the flag, as the saying goes, is a way of making aircraft more expensive, and therefore less useful, than they might be.

The technical extravagance of the major manufacturers tends in the same direction. The unit of accounting in the development of a new aircraft or of its engines seems to have settled down at

£1,000 million or thereabouts. (Boeing's past successes may owe something to its economical ways of working.) Even allowing for the technical sophistication of the new machines and their power plants, and for the value of the potential prizes to be won, it is hard to see how costs on this scale can be justified. Part of the explanation is the ambition of most manufacturers to keep in being the small armies of skilled people which constitute their design teams. It would do no harm, and indeed might even benefit the aircraft industry itself, if the wisdom of these practices were closely examined by people skilled at telling not merely whether carbon-fibre composites are better for some technical purpose than the new aluminium-lithium alloys, but whether the processes of design and development need be as expensive as they have become. The economic benefits could be substantial — more flexibility in too tightly hierarchical an industry, easier access by the people to a technology whose benefits are already great, but which could be huge. Governments will not attempt the hard-eyed scrutiny that the aircraft industry needs, but would undoubtedly welcome the results. The responsibility falls squarely on the technical community. Why not (for Britain) Farnborough? ☐

Too brief encounter

The likely outcome of the space weapons talks is that the negotiators will meet only to adjourn.

THOSE who believe diplomacy a dull business should think again. Some weeks ago, the Soviet Union invited — some would say challenged — the United States to a conference at Vienna on the use of the space above the atmosphere for the siting of military weapons. The date suggested for the opening of the conference is 18 September, less than two weeks from now. Yet as things were earlier this week, nobody knew for certain whether two small armies of diplomats would actually arrive, ready to begin talking to each other. Careful people that they are, the potential members of the negotiating teams have arranged for hotel rooms to be booked on their behalf.

But Mr Konstantin Chernenko is clearly a little anxious that nothing at all will happen. In his interview with *Pravda* published at the weekend, he made noises apparently designed to soften the quarrel there has been with the United States about the agenda for the talks. If, he suggested, the United States would agree to talk about space weapons only at Vienna, he might ensure that there would be negotiations at another place and time about the issues the United States says it must discuss — the disposal of nuclear weapons in Europe and more broadly. Unfortunately, Mr Chernenko seems to have reckoned without the American calendar, temporal and electoral. Last weekend was Labor Day weekend, when citizens of the United States do not labour. And with President Ronald Reagan off to a good start in his campaign for re-election only two months from now, giving hostages to fortune in a negotiation that could not be complete before election day was bound to go against the electoral grain. So the State Department quickly announced that there was nothing new in what Mr Chernenko had to say, even though it is clear that it provided an opportunity that could have been exploited if anybody had felt so inclined.

What happens next? The most serious danger is that the preoccupation of even enlightened spirits in the United States with the election will blind one partner in the talks to the importance of what needs doing. Meanwhile, even the President and his advisers might prudently calculate (as they should have done during the last election campaign) that talks with the Soviet Union will be necessary once the dust has settled. Just as well to get something started before the election, but not to get too deeply embroiled in negotiations until the polls have taken place. So the likely calculation, at the State Department, is to aim at a preliminary encounter over space weapons, a polite statement of the need to talk about other things as well and an offer to adjourn the impending negotiation until something can be arranged. Whether Mr Chernenko and his colleagues will agree is entirely unclear. ☐

Academic divisions

Polytechnics should be made into universities or otherwise transformed.

THESE are busy but depressing days for polytechnics, the Cinderellas of the British system of higher education. For this is the season of the year at which would-be students denied places at universities turn to the polytechnics in the hope of being fitted in. On past form (and the figures released earlier this week by the Universities' Central Council on Admissions), something like 100,000 applicants for university places will be refused (but 75,000 will be accepted). Those turning to the polytechnics for an undergraduate education will, however, be douched with cold water by the report now published of a study of *Expectations of Higher Education* commissioned in 1980 by the Department of Education and Science and carried out by the Department of Government at Brunel University, the head of which (Professor Maurice Kogan) is as much an educationalist as anything else. The short message of a formless document is simple — employers are biased against the recruitment of graduates from the polytechnics, preferring the products they are used to — graduates from universities and especially from Oxford and Cambridge. This unsurprising news will be a slap in the face for many of the young hopefuls now hurrying off to the public sector in the hope of finding places as undergraduates. For those concerned with the future of British higher education, however, it should be a reminder that present arrangements are far from being sensible, and should urgently be scrapped.

Britain is not unique among industrialized nations in maintaining two kinds of institutions of higher education. Usually there are more vocational educational institutions. The distinctiveness of the British system is that the polytechnics were established overtly as an alternative to the university system, and have ever since been advertised as such. Whether the motives of the minister responsible, the late Mr Anthony Crosland, were political (British universities were already becoming unpopular with politicians), economic (the technical colleges from which the polytechnics emerged were thought to be cheaper) or pragmatic (what else could have so quickly increased the supply of graduates?), the designation of 26 polytechnics as graduating institutions within what is called the binary system turns out to have been a mistake. If there are two classes of institutions, one of which is seen to attract less highly qualified students (and probably less talented teachers), yet which has failed in nearly twenty years to make a characteristic mark, who can be surprised if that one continues to seem second-rate?

The prejudice of employers of all kinds against polytechnic graduates is understandable, even forgivable, on the basis of the data collected by the Kogan study. The school-leaving qualifications of polytechnic students, which span a spectrum overlapping with that of university entrants, are in general and on the average lower than those of new university undergraduates. While any process of education must somehow be capable of improving on people's attainment at the outset of their academic careers, nobody should be surprised that some of these measurable characteristics persist — and that when jobs are hard to find, employers take the easy way out. But all this is unfair to the polytechnics, many of which are in every way at least as competent as fully-fledged universities, and as successful in preparing their students for valuable careers. Especially because of the way that, in Britain, the sharpness of the binary division is accentuated by the academic snobbery which is rife, there is the strongest possible reason for its abolition. The sensible course would be to set a term, say five years from now, when all these institutions would be freed from the apron-strings of the local authorities that now watch over them, some to become rounded institutions of higher education, others to make their way in the world in different ways, perhaps by providing the distinctively vocational higher education that was originally, and inconsistently, part of the reason for their creation. Others might have to sink without trace. ☐

Biotechnology

Cohen–Boyer patent finally confirmed

Washington

AFTER 10 years of legal argument, Stanford University has finally been granted a "groundbreaking" product patent covering recombinant DNA molecules as produced by the Cohen–Boyer gene cloning technique. The Cohen–Boyer technique is fundamental to most genetic engineering research, and the new patent, which includes the uses of recombinant DNA in bacterial cells, confirms Stanford's proprietary hold on the fledgling biotechnology industry. A process patent covering Cohen–Boyer was granted to the university in 1980, and is considerably strengthened by the new product patent.

At present 66 companies are licensed to use the technology by Stanford, which shares rights with the University of California at San Francisco. Others have been holding back from paying the $10,000 annual licence fee until the status of the product patent became clear. The university will from now on enforce both, and it is likely that most industrial users of the technique will pay up: as one patent attorney put it, "you'd have to be out of your mind to challenge a $10,000 licence" since legal costs would inevitably be much greater than the licence fee.

The Cohen–Boyer technique uses a bacterial plasmid to transfer foreign DNA into a host cell. While the cost to licensees of using the technique might be modest, the value of the patents to Stanford and the University of California, San Francisco, is likely to be considerable, especially when genetically engineered products become more widely available. The universities will share royalties at the rate of 1 per cent for the first $5 million of sales, decreasing to ½ per cent on sales over $10 million. Use of the Cohen–Boyer technique in pure research is not restricted, but the partners have already earned almost $3 million on the process patent from commercial companies. The two inventors, Dr Stanley Cohen of Stanford's school of medicine and Dr Herbert Boyer, professor of biochemistry at the University of California, San Francisco, have both waived their rights to a one-third share of revenues. The income is used by the universities to support graduate student programmes. The new patent will prevent, for example, companies avoiding royalty payments by manufacturing abroad and importing into the United States.

The Cohen–Boyer saga has been controversial on several counts. In 1982, the Patent and Trademark Office tentatively rejected the product patent on the grounds that the original application incorrectly specified the origin of the plasmid called pSC101. The plasmid was described in the application as arising from a naturally occurring plasmid by recircularization of a fragment itself produced by hydrodynamic shear. A later paper by Cohen and a co-author revised this view and left open several possibilities for the plasmid's origin.

A patent specification must under US law provide sufficient information to enable a person "skilled in the art" to reproduce the invention. In granting the new product patent the patent office seems to have recognized that a description of how to make a product contains sufficient disclosure if it is operationally accurate, even if the proposed interpretation is incorrect.

Also related to the disclosure requirement was the objection that Cohen and Boyer failed to deposit samples of their plasmid in a public repository at the time the application was filed. They did, however, make samples available to qualified investigators, and the patent office seems now to have accepted that this practice was not unduly restrictive. This aspect of the case has caused some consternation to lawyers, who see dangers in allowing an organism in a private repository to suffice as a patent standard. Not least of these dangers is the natural inclination of a scientist to replace a strain isolated for a specific purpose with a better specimen should one turn up.

Other issues raised have included that of whether the invention was non-obvious and whether the scope of the application was too broad. Despite some fleeting references to the possibility of artificially recombining DNA published more than a year before the application, the new ruling confirms the originality of the idea. Stanford has withdrawn an earlier claim over the use of recombinant molecules in eukaryotic cells to expedite the present patent, but is still pursuing that claim in a separate undisclosed application.

The patent office usually declines comment on interpretation of its decisions, although an official said the judgement did "not represent a change of policy". A detailed policy statement on biotechnology is now being prepared by the patent office and is expected to clear up much of the confusion left in the wake of the Cohen–Boyer patent. **Tim Beardsley**

Industrial training

Britain lags well behind

A NEW approach to vocational training and education in Britain is essential if British industry is to compete successfully in world markets. This is the major conclusion of a report entitled *Competence and Competitions* prepared by the Institute of Manpower Studies for the National Economic Development Council (NEDC) and the Manpower Services Commission which compares, for the first time, British investment in training and human resources with that of West Germany, Japan and the United States. All three of these countries clearly recognize education and work competence as an important key to their economic success, some major companies in Japan and the United States, for example, investing between 2.5 per cent and 3 per cent of their sales revenue in training.

Young people in Germany, Japan and the United States are better equipped for working life than their British counterparts, the report says, because more of them participate in education and training programmes and for longer periods. In Japan, 84 per cent of school leavers voluntarily continue their education to the age of 18, in Germany the figure is 70 per cent, and in the United States 73 per cent of those aged between 16 and 24 are enrolled in some form of further education. It is quite sobering to realize that, in Britain, education beyond 16 is the exception rather than the rule; two-thirds of all 16 year olds enter the labour market.

Britain trains only 15,000 graduate engineers a year compared with Japan's 70,000. But, the report says, the most acute shortage is among craftsmen, technicians and middle-level engineers, and Britain must counteract the decline in apprenticeship training by creating alternative training routes.

Education and training in Germany, Japan and the United States is funded primarily by industry. In Germany, for example, employers bear 80 per cent of the cost of the 1.67 million apprentices under training. All three countries have responded to the recession by accelerating their training programmes and so investing money in the future.

The report makes twenty-four specific recommendations. Among other things, it calls for measures to enable 80 per cent of young people in Britain to enter the job arena with qualifications relevant to their employers and for Britain to emulate Germany's achievement of having 12 per cent of its adult workforce on work-related education and training. Industry, it says, must take the responsibility for funding new engineering training facilities. The report calls on the government, trade unions and employers to make a positive commitment to these aims.

Marcus Chown

European high-energy physics

Poor marks for enterprise

In the thirty years since the establishment of CERN, the European Organisation for Nuclear Research near Geneva, the laboratory has produced only two "crucial discoveries" compared with a dozen or more at United States laboratories, whose total cost is similar, and may even be less.

This is the bottom line of a lengthy balance sheet, with many other conclusions and observations, drawn up in nearly two years' work by social scientists Ben Martin and John Irvine, of the Science Policy Research Unit at the University of Sussex, and published today (6 September). The two-part report is certain to be influential in this particular reappraisal of its membership of CERN.

The first CERN discovery categorized as "crucial" was in 1973 ("neutral currents", a new form of weak interaction). By then, US laboratories had discovered a second neutrino, the omega-minus (the beginning of the quark model), charge-parity-violating interactions, deep inelastic scattering (which indicated that the proton really had components, now known to be quarks) and more. CERN, on the whole, has been thorough but dull, say Martin and Irvine — CERN lacked "bzazz". But the second of CERN's crucial discoveries is very recent (the intermediate vector bosons W and Z found last year), is attributable to a new adventurousness at CERN and, according to the review, "to a certain extent the balance of power in experimental high-energy physics between North America and Western Europe seems to have reached a turning point".

Martin and Irvine are famed (or notorious) for their previous critical assessments of the Jodrell Bank radiotelescope, British astronomy (notably the Isaac Newton telescope) and the Daresbury electron synchrotron NINA. But their review of CERN is more important as it may affect real policy in two ways: first, a British scientific committee (see box) is studying whether Britain should remain a member of CERN, given the present £27-million price tag; and there are indications that Martin and Irvine's much-improved approach to scientific assessment in the CERN report is finding favour among British policy-makers, and could be applied to other fields. (A study has already been made of protein crystallography, for example, and delivered to Sir David Phillips, chairman of the Advisory Board for the Research Councils, which allocates basic research funds among the different research councils in Britain.)

But does the Irvine and Martin method work? The two researchers' earlier reviews drew criticism that in assessing scientific productivity (or the lack of it) in terms of indicators of publication volume, citation frequency and peer ranking of laboratories, they ended up with too bleak a picture of what began to seem "targets" rather than mere subjects for research. There were mitigating circumstances, and forms of productivity unmeasured by the indicators.

But Martin and Irvine's present effort — two papers published in *Research Policy* — can hardly be criticized on those grounds. The CERN survey is sophisticated, and the two investigators clearly recognize a development in their technique. For example, they previously described their method as one of "converging" indicators, thus begging the question of whether or not the indicators do indeed converge on a single black-or-white assessment of a laboratory. In the case of CERN, the indicators clearly do not converge, and, write the researchers, "the results based on each indicator need to be carefully interpreted". Interpret they do, basing their analysis on 182 interviews with particle physicists from the Soviet Union to the United States.

High-energy physicists, even those at CERN, who have seen draft versions of the papers describe the analysis as fair, balanced and (mostly) accurate. CERN is admitted to have just missed the boat on many occasions. The two quarks called charm and bottom, which highlighted a revolution in physics in the 1970s described by Martin and Irvine as "the American Revolution", could have been found at CERN, the study claims. Missing the discovery of these particles was described by one physicist interviewed by Martin and Irvine as "a tremendous failure".

CERN even produced serious errors. One particle, the $A2$, was claimed — falsely, as it turned out — to be split, or twofold, creating a puzzle which absorbed theoreticians for nearly five years during the late 1960s. But similar errors were made in the United States (the "high-y" anomaly of Fermilab which caused equal consternation in the 1970s). Here the balance sheet is even.

European dimension

Sir John Kendrew, the molecular biologist who is chairing a committee looking into Britain's future commitment to CERN, said last week that the Irvine and Martin report (see above) will be distributed to all the members of the committee — but along with many other papers it had received ("too many actually", said Sir John).

His committee will report "early next year" to the Science and Engineering Research Council, together with the Advisory Board for the Research Councils, and the committee plans to visit CERN in October, Sir John said.

Just what impact the committee's views will have remains to be seen — Sir Keith Joseph, Secretary of State for Education and Science, announced on setting up this committee that its scientific review would be "without prejudice" to a final (political) decision on CERN membership. The final decision will have to be taken in the wider context of Britain's whole relationship to Europe. Robert Walgate

In terms of positive results, CERN's first big machine, the 28 GeV proton synchrotron(PS), though on line before the equivalent alternating gradient synchrotron (AGS) at Brookhaven, was nowhere near as productive at the beginning. Physicists attribute this, above all, to lack of experience in the design of high-energy physics experiments in Europe. Then the intersecting storage rings (ISR), designed to collide PS protons with each other head on, was a brilliant technical success — but failed to produce revolutionary physics. (It helped in understanding the quark structure of nuclear particles, but could have seen and not missed charm and bottom.) Martin and Irvine suggest the machine was underexploited by CERN management. The 400 GeV super proton synchrotron (SPS) that followed came too late — more than four years after Fermilab in the United States had creamed the energy region — and had to rely on tidying-up (which, nevertheless, it did well, with resources that were considerably greater than Fermilab's).

Dr Herwig Schopper

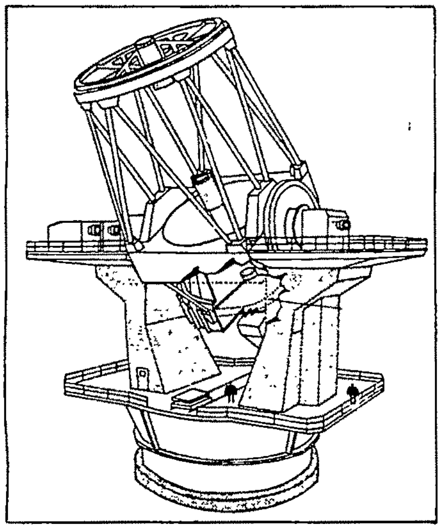
The lesson, if there is a single one, is that Europe's laboratory was run too much by committee, whereas American laboratories owed more to individual flair. (Maurice Goldhaber at Brookhaven, R. R. Wilson at Fermilab and Pief Panofsky at Stanford Linear Accelerator Center are singled out.) But Martin and Irvine say that things are changing at CERN under director-general Herwig Schopper and that a more individualistic style has emerged.

Nevertheless, CERN has committed itself now to just one future machine and its 15-mile tunnel, the electron accelerator LEP now under construction. A future and more controversial report by Irvine and Martin will discuss the prospects for LEP, and at lease one official involved in the British decision to support it has said he wishes he had had the report before him when he said yes. **Robert Walgate**

Japanese astronomy

Plan for telescope on Hawaii

JAPAN's astronomers, led by Professor Kei-ichi Kodaira of the Tokyo Astronomical Observatory, have announced plans to build what could be the world's largest optical telescope on Mauna Kea in Hawaii. A 7.5-metre single-mirror telescope is being called for — a considerable advance on the Mount Palomar 5-metre, or the 6-metre telescope now apparently operating at Zelenchukskaya in the Soviet Union.



Whether the Japanese telescope turns out to be the world's largest depends upon how US plans for a multiple-mirror 15-metre telescope (the NTT, new technology telescope), possibly on the same site, come along. Records, anyway, are not what the Japanese are after: the telescope is being designed to complement, not compete with, NTT and to mesh neatly with Japan's proven capability in millimetre-wave astronomy and X-ray satellite astronomy.

Although the telescope plan has only just been made public, it has been vigorously discussed for some years. Ten years ago, the astronomy committee of the Science Council of Japan — the major representative body for scientists through which virtually all plans for large-scale facilities must pass — recommended building a 4-metre telescope. In those days, as now, Japan's biggest optical instrument was the 1.88 metre installed in 1960 at Okayama.

The 4-metre telescope was not built, however, and much of the astronomical community's energy went instead into backing the construction of the world's largest millimetre-wave telescope at Nobeyama. By the time attention had turned back to the need for an optical telescope, technological advances had been made and a 4-metre telescope was clearly too small, given that it will be 1990 before it is in operation.

Over the years two kinds of obstacles had also surfaced. First, Japan lacks any kind of central astronomical institute. The "Tokyo Astronomical Observatory", which has the major share of top-class facilities with seven observatories including Nobeyama, is actually a part of the University of Tokyo and does not have the authority to speak for all universities and astronomers, either to the government or to those in foreign countries from whom cooperation is necessary. Second, Japan has no history of large optical telescope building. Although there is no bar to foreign manufacturers, the newness of the design means it will be essential to have engineers close by to work with — and to charm with the technical challenge of the problems, rather than potential profits, for telescopes are not going to sell in bulk.

While neither of these problems has actually been solved, there is confidence that the Tokyo Astronomical Observatory can gradually move towards a central institute status similar to that held by ISAS and KEK (the space and high-energy physics research institutes) and that while international cooperation may be needed for the mirror design, Japanese engineers can handle the tracking and mounting.

The next question, which must be settled this year, is mirror design itself. There are advocates of both the honeycomb type pioneered at the Steward Observatory of the University of Arizona and a solid meniscus. Either way, the telescope aims at high performance not only in the optical region of the spectrum but also well into the infra red, with a resolving power around 0.1 arc seconds and a field of view wide enough (around 0.5 degrees) for efficient observation of 20th magnitude stars. This performance will complement that of NTT, which in aiming for a very large collecting area that will allow spectroscopy of extremely faint stars, will inevitably sacrifice some resolution (0.3 arc seconds has been cited), and the space telescope, which will have no infra red facility (at least to begin with) nor the combination of high resolution and wide field of view that the Japanese telescope will be able to offer.

Prime scientific objectives for the new telescope will obviously be stellar and planetary formation and the formation and evolution of galaxies. As astronomy is getting "redder and redder", the infra-red capacity will be of vital importance and allow a look back to early evolutionary stages of great cosmological significance. As two-dimensional infra-red detectors become available, the capacity of the telescope can be further expanded.

If the project gets the go-ahead, it will break political as well as scientific ground. At present, the Japanese Government owns no major research facilities abroad (other than Antarctic bases) and a move to Hawaii will be a major piece of "internationalization" requiring legal changes and the passage of a couple of bills through the Diet. Contacts have already been made with the University of Hawaii and the state governor for there is not much space left on Mauna Kea: with a proposed limit of 13 telescopes, six have been built, two planned and more are expected to be listed soon.

The astronomical community is expecting that all the basic plans for the telescope will be complete in a few months. Beyond that it is up to the University of Tokyo, rather than the observatory, to submit the request officially to the Ministry of Education, Culture and Science and for it to press for funds — estimated at around 20,000 million yen — from the government. If all goes well, money for a two-year evaluation programme will be granted beginning in 1986 and will be followed by five years of construction.

There is no official word yet, but the astronomical community seems confident that the money will be found. Behind-the-scenes opinion sampling which always precedes the emergence of a decision in Japan appears to have been going well. By 1986 they should know for sure. **Alun Anderson**

Open University cuts

THE Open University (OU), in common with other British universities, is facing a cutback in government financial support. The proposed cut comes after four successive years in which OU has seen its state aid shrink in real terms. Meanwhile, its efforts to economize have resulted, over the same period, in an increase in the proportion of total university expenditure met by non-government sources from 15 to 25 per cent.

OU is concerned that the cuts will lead to a reduction in its student numbers and its courses and will also seriously limit its ability to provide teaching through television and radio programmes, and it disputes the goverment's assessment of the precise magnitude of the planned cut. Sir Keith Joseph, Secretary of State for Education and Science, has insisted that the cut, over the three-year period until 1986, will amount to just £4.5 million. OU claims, however, that it will have to make a total reduction in expenditure of some £13.2 million by 1986, and has gone to some lengths to prove its point.

In arriving at its figure, OU has estimated the net increase in its costs (1983–86) due to inflation and "unavoidable" costs (equipment renewals, superannuation increases, etc.), after taking into account the expected rise in income from student fees during the period.

About 100,000 students were enrolled at the Open University last year, Britain's only university with no formal entrance requirements and open to people who, through financial or job constraints, cannot attend a full-time institution.

Marcus Chown

Space shuttle

Discovery takes off at last

Washington

OFFICIALS of the National Aeronautical and Space Administration (NASA) could almost be heard breathing a collective sigh of relief last week when the temperamental shuttle orbiter *Discovery* finally cleared the launch tower at Kennedy Space Center, Florida, on 30 August. Two previous launch attempts were aborted with the crew already strapped in and ready to go, and a scheduled launch on 29 August was called off after deficiencies were found in computer software controlling critical flight functions. NASA has tried to keep its commercial customers happy by rescheduling satellite deployments, but at the back of everyone's mind is the knowledge that NASA will now be able to launch only 6 shuttle flights this year even if there are no further problems. Originally 10 were planned.

The 29 August attempt was abandoned because simulations confirmed that under certain emergency conditions (such as the failure of one of the five on-board general-purpose computers), commands to the shuttle's "major event controller" could be delayed by as much as one second, enough for them to be rejected. The controller switches such critical events as the separation of the shuttle's external fuel tank and solid-fuel booster rockets, not to mention the bolts that secure the orbiter to the launch pad. NASA stresses that the postponement was a "safety first" decision and that a launch on 29 August would probably have been successful.

The difficulty appears to have been caused ultimately by inadequate testing procedures, since NASA insists that the on-board computers and the event controller had consistently performed to expectation in pre-flight simulations. The timing problem was first noticed during separate tests on software under development for a future shuttle mission. Parallel tests were then run on *Discovery's* computers and a similar effect confirmed: delays arose when the system had to deal with several events occurring almost simultaneously. The difficulty was rectified by a software patch, and go-ahead for the 30 August launch was given after a hastily-convened telephone conference of engineers. The inability to foresee exactly how a system of interacting computers will behave under non-standard conditions is presumably a problem that will not easily go away, because programs and hardware are continually being modified.

NASA was putting a brave face on the delay before last week's successful launch, and spokesmen were keen to point out that the last fault was only a potential one, and then only under worst-case conditions. Indeed, one suggested, it was to NASA's credit that it employed engineers able to raise such hypothetical problems. Whether NASA's customers will be able to see further delays to the shuttle programme in quite this light remains to be seen. American Telephone and Telegraph (AT&T), whose Telstar 3 satellite was reassigned to the present mission after the original failure to launch *Discovery* in June, declares itself content with the service given by NASA so far. However, AT&T has not directly lost out as a result of NASA's latest rescheduling, which involved combining parts of the payloads of two separate missions. Less pleased, presumably, is Hughes Communications Services Inc., whose LEASAT-1 satellite has been held up by shuttle breakdowns, and a movie company whose cameras have had to be left behind.

Besides three commercial satellites, *Discovery* was carrying three major NASA experiments to provide information that will be needed for designing a space station. These employ a 30-metre long folding panel such as might be used for solar cells; on the present flight, however, most of the cells will be dummies. Besides characterizing the test cells' performance, the array will be used to gather information on structural vibrations. The shuttle is also carrying a continuous flow electrophoresis system belonging to McDonnell Douglas and Ortho Pharmaceuticals Inc., which will further examine the feasibility of commercial pharmaceutical manufacture in the zero-gravity environment of space. Earlier versions of this experiment flown in previous shuttle missions have given encouraging results, but the partners are not telling what exactly they have in mind to produce.

Tim Beardsley

Soviet space programme

Remote sensing in prospect

FURTHER Comecon participation in the Soviet manned space programme is not foreseen in the "near future", Academician Vladimir Kotel'nikov told a press conference in Moscow last month. "Very broad and successful" international cooperation of the socialist countries of the world would, however, continue, he said. The "most impressive", he noted, will be the planned Vega mission to be launched in December, in which a two-part probe will be sent to Venus, one part then making a soft-landing on the planet and the rest continuing the rendezvous with Halley's comet, passing through the tail (at some 10,000 km from the head) in March 1986. The 130-kg Venus payload will include equipment developed in Bulgaria, Hungary, Poland and Czechoslovakia, and also Austria, France and West Germany. East Germany will provide the ground equipment for decoding the signals.

Apart from Vega, future *Interkosmos* projects seem likely to concentrate on what has always been one of the main aims of the programme: the use of remote sensing to aid the economies of the member nations. Photography from space of the homeland of the "guest" cosmonaut always formed part of the manned *Interkosmos* flights (although in the case of the Cuban cosmonaut this was apparently carried out by his Soviet "hosts" after he had returned to Earth). An *Interkosmos* symposium in Dushanbe last November, in which the Interkosmos cosmonauts took part, summed up the experience of the manned programme with particular emphasis on the value of remote sensing for locating mineral deposition and "enhancing" agricultural productivity.

The annual conference of leaders of the national coordinating bodies of *Interkosmos*, which met in Prague shortly before the Dushanbe conference, had likewise come out strongly in favour of remote sensing, the most practical route to making cooperation in space "more efficient".

A major step in implementing this joint remote sensing programme began last week in north-west Azerbaijan, involving representatives of all the European Comecon countries except Romania, working in conjunction with the three Soviet cosmonauts aboard Salyut-7. The ground team will make observations of the "spectral characteristics" of natural objects in the area (including the Mingechaur reservoir), which would be coordinated with aerial photographs and also photographs and spectrographs taken from the Salyut station. The orbital and airborne data are received by a special automated data-processing unit developed in Baku. The experiment is intended both to develop the "fundamentals of remote sensing of the environment" and also to provide practical recommendations for the utilization of agricultural land, pasture and reservoirs. For the Comecon participants, it is primarily a training exercise for future projects in which they will cooperate with Soviet space-crew passing over their homelands.

Interestingly, the experiment is co-ordinated not from Moscow or Baikonur, but by the Institute for the Remote Sensing of Natural Resources of the Azerbaijan Academy of Sciences. This institute has already obtained good results in predicting floods and mudslides in Azerbaijan, monitoring the state of the pastureland and forecasting the yield of the cotton crop. Delegation of coordination to the Academies of the Union Republics seems to be becoming a feature of the *Interkosmos* programme; the Vega mission is being coordinated by the Ukranian Academy.

Vera Rich

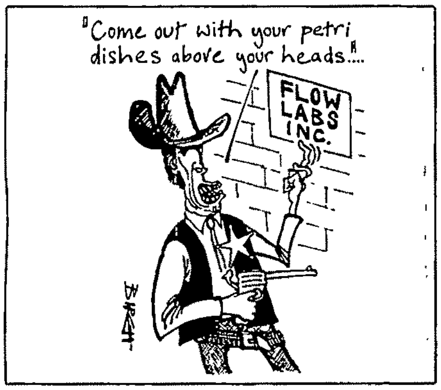
Product contamination

FDA sends in the marshals

Washington

US MARSHALS acting for the Food and Drug Administration (FDA) last week seized $4 million-worth of tissue culture and related products belonging to Flow Laboratories Inc., a major supplier to clinicians and researchers. The FDA action was taken following an inspection in April that found numerous instances of bacterial contamination of products and violations of FDA's code of good practice.

A federal judge later allowed Flow to recover raw materials and products used only for research. Flow attorneys argued that the FDA action was unlawful because marshals took "everything they could lay their hands on", and that cell lines would quickly die without attention. The company had been forced by the FDA action to close its manufacturing facility at McLean, Virginia.



"Come out with your petri dishes above your heads!..."
FLOW LABS INC.

Flow does not dispute most of the hundred or so complaints listed by FDA in April, but, according to Douglas Poretz, director of corporate affairs, the company has since made vigorous efforts to comply with the FDA observations. The complaints originally made by FDA allege that procedures for testing contamination were inadequate, that "clean" and "dirty" areas were not kept separate and that sterilization equipment failed to work to specification. Several products were not routinely tested in the manner claimed and significant contamination was present in others. In some instances, according to FDA, the company had failed to notify customers after a faulty batch was detected.

Flow says that after the April inspection, several senior staff were fired and outside consultants were brought in. But problems continued, and more than 10 product recalls were made during July. An anonymous Flow employee telephoned FDA to say that some products known to be contaminated were being shipped to customers. FDA finally acted on the basis of the product recalls without carrying out a second inspection.

Flow General Inc., the parent company, has been through a disastrous 2 years and has sold off parts of its operation after sustaining losses last year of $10 million on sales of $129 million. Legal difficulties over a defence contract led to many staff resigning, and Flow Laboratories' factory in Scotland had to recall many products because of mycoplasma contamination from the water supply. A trial to examine the legality of the FDA action will be held on 12 September. **Tim Beardsley**

French nuclear energy

Overpowered

FRENCH pressurized water reactors (PWRs) now provide more than half of French electric power, and last year "had the best performance ever" after a rather worrisome year in 1982, according to a spokeswoman for Electricité de France (EDF), the French national utility.

In 1982, French reactors were troubled by problems with the radiation embrittlement of certain clips ("*broches*") which held fuel in place, which resulted in long shutdowns for repairs and consequently very poor operating figures for that year. It was feared that the French method of large batch production of a very small number of designs might have been cheap, but risky. If there were a fundamental flaw in the design, at worst all the reactors could go down, and French electricity production would be halved. What had seemed like sense began to seem like foolhardiness.

But all along EDF claimed that these were mere teething troubles. The French nuclear system had grown so rapidly, most of it was very new: the *broches* problem was a problem of running-in, said EDF (crossing its collective fingers meanwhile).

Now, however, the *broches* problem is past and all is well. In the first half of 1984, French PWRs have turned in availabilities (energy produced divided by energy theoretically capable of production, if the reactors all ran full-time) of over 80 per cent, compared with figures around and under 60 per cent a year earlier. West Germany and Japan are said to be showing similar good results.

But the problem in France now is what to do with all that electricity. The French Government, in announcing a slimmed-down nuclear construction programme last year, asked EDF to aim at increasing French electricity consumption by 40 per cent by 1990, a task which requires finding some inventive new uses for electricity. Domestic electricity consumption has indeed risen this year by about one per cent a month — but there are no obvious reasons why (the French economy has been stagnant). The other possible opportunity of filling the gap is export. Given the tardiness of the other European power programmes in substituting for coal and oil, this must be the greatest opportunity facing the French utility in 1990.

Robert Walgate

French universities

Now one for Le Havre

THE new French minister of education, M. Jean-Pierre Chevènement, is conforming to his old, expansionist style, and belief in investment in "grey matter". He has created a new university.

This will be the Université du Havre, a university for the channel port of Le Havre, the third port of Europe, the twentieth city in France and one that has been seeking university status for its various colleges for some fifteen years.

But "the university of where?" asked a surprised spokesman for the Centre National de la Recherche Scientifique (CNRS), France's principal source of funds for basic research, when confronted with the news on Monday. Admittedly the university had been created during her holiday (last Tuesday in fact), but this may be a small indication that the university is not immediately going to startle the world.

Actually, Le Havre will be the 64th French university, counting the vast 13-university University of Paris as one, to compare with 48 in Britain (counting the University of London as one), for about equal populations in the two countries. The comparison reflects the effects of the troubles of May 1968, when student pressure and political expediency led to the creation of many new universities in France and elsewhere on mainland Europe, but few in Britain.

The expansion might have been thought to be over in France, but that was reckoning without M. Chevènement — and the fact that the new Prime Minister, Laurent Fabius, owes his seat in the national assembly to the electorate of the Seine-Maritime department, which includes Le Havre.

The university is expected to concentrate on matters concerning international trade, and will begin with a £3 million cash grant to create a 6,300 sq. metre campus. It will combine an existing IUT (an institut universitaire de technologie, something like a British polytechnic) of 1,000 students, and other units that have previously depended on the Université de Rouen, 40 miles up the Seine. Its creation thus runs counter to policies observable in other countries (notably Britain), which tend towards a combination of facilities among universities.

According to figures collected by UNESCO, the United Nations Educational, Scientific and Cultural Organisation, France ranks fifth in the world in terms of the proportion of the population studying at university after the United States, Sweden, Japan and the Soviet Union. West Germany and Britain follow after France.

Robert Walgate

Too little Indian zeal

Sir — To my mind, the basic problem with Indian academics is that their sense of social responsibility is often regrettably poor. Only a very few educated people are ready to produce an amount of work that will justify their salaries. Even in a research institution such as the Tata Institute of Fundamental Research, where the annual input is equivalent to US$6 million, the annual output is about 270 research publications in the journals, shared by more than 300 top-level scientists. These scientists are potentially as capable as their counterparts in the West, but we become lazy in our home country. The very same people, when abroad, are compelled (possibly by example) to work hard, each producing as many as 5–10 papers a year. I am not saying that quantity is a measure of quality, but I certainly believe that, for the average research worker, quantity does beget quality.

The situation is much worse in Indian universities and other research organizations, which submit thousands of eyewashing project reports to their financiers, in preference to publication in one of the standard journals. Mainly on the basis of these obscure reports, however, the government measures national progress. Notwithstanding the rosiness of any such picture, the country seems to receive a poor return for its heavy investment. People are adequately paid for working, but the moral sense of their official responsibility fails to meet the minimum standard.

Mrs Indira Gandhi made a very brave attempt to improve matters by imposing emergency rule in 1976. All officials in positions of responsibility were forced to keep full office hours and to carry out their duties properly. This obviously irked all the educated parasites, who successfully brought about a ballot-paper revolution against her. So the poor lady has now learned that morality cannot be taught by force. We must rely on an appeal to people's individual consciences for any improvement — and I have written this letter in order to make such an appeal. A country can progress only if every citizen is willing to carry out his or her job responsibilities with sincerity and commitment. That is all that is needed in the first place, a step which has already proved to be the prime key to success in the West, the Soviet Union, China and Japan.

Many important plans in India have already failed because neither the planners nor the executors did their jobs properly. People are willing, for as long as a year if necessary, to weigh all the pros and cons before for example buying a motor car for themselves, but will lay out a hundred times as much on an expensive official project after as little as two weeks consideration. If that project is doomed to fail, it is not because of any failure of hands or brain, but because of a lack of commitment. The chance of success depends much more on this factor than merely saying later that the project had been too ambitious. One must go for ambitious projects, but wholeheartedly.

Another problem for India is that it is producing more specialists than it needs. In the United Kingdom, only 2.5 per cent of students go to university, but in India, the fraction is about 15 per cent. This means not only that some incompetent students sneak into higher education, but also promotes a brain drain to other countries or to other types of lucrative jobs. The aim of the universities is quite lost in the burden of teaching, while the research institutions fail to hold the meritorious scholars, because of either poor rewards or poor guidance. The latter seems to be the greater problem. Unless the professor or director is prepared to do more brain work than his subordinates, there is no justification for either his rank or the wastage of national money on him. Only a very committed leader can create an atmosphere conducive to equal commitment from his staff. Will the right people ever set the right examples?

Suggested remedies

Sir — For the sake of completeness of your appraisal of Indian universities (*Nature* **308**, 581-600; 1984), I would like to add the following comments on higher education in India.

Since independence in 1947, India has taken big strides in higher education, especially in science and technology. In the past two decades, the number of institutes of higher learning has increased enormously, but the provision of new institutes without consolidating the existing ones has had an undesirable effect on the quality of education. Indeed, many institutes have become degree-granting bodies rather than places of learning.

Almost all universities suffer from the age-old problem of "inbreeding". Unlike those elsewhere, Indian students after graduation are usually employed at their own *alma mater*, and even a very bright graduate will have a tough time getting a job at any other university. As a result, some universities have certain departments specializing in only one discipline — that of the preceptor. This has essentially stifled the influx of new ideas and progress and also creates a situation in which the head of a department, being senior to the rest of the faculty, has an absolute say in the running of his department. His colleagues, most of whom were his own students, do not dare to voice their feelings. Since the fate of an individual faculty member is decided by only one person, the spirit of competition is lost at the very beginning of tenure and every faculty member has. to promote himself by means other than teaching and research. With the increasing linguistic chauvinism in the universities, science education has suffered a great deal. A developing country such as India needs ideas and literature from the advanced countries. But since education in English has been trimmed to promote one of the fourteen official languages of India, students cannot grasp the progress of developed nations. This is a self-defeating and shortsighted approach which has been forced on the country by self-promoting educationists and politicians. The effect has inevitably been an overall decline of science and technology education in India.

Striking has become a pastime for Indian students. Students go on strike for a difficult question paper, for failing grades or for compulsory promotion, but never for better teachers. Since the strikes are almost invariably resolved to the students' advantage, they have become an important tool in obtaining degrees, mainly because many students are admitted to university who are not sufficiently well qualified to be there.

India must find ways to eliminate the pitfalls inherent in the existing system. To start with, there should be a ban on appointments to a faculty from among its own graduates. English should be made essential for prospective scientists and technologists. There should be a nationwide qualifying test for university entrance. Educationalists and politicians should do everything they can to formulate progressive and farsighted policies on education and should rise above petty political advantage. It is after all education which eventually leads a nation.

Red Sirius

Sir — The correspondence about Homer's wine-coloured sea reminds me about red Sirius. Several ancient authors call Sirius red, even though it is white with a slight bluish tint. This is another object which seems to have been called red even though blue would have been a better description.

Göran H. I. Johansson
Lund Observatory,
Box 1107,
S-22104 Lund, Sweden

Sir — Homer's wine-dark sea is not the only such problem in Greek culture. It is well-known by astronomers that in Ptolemy's *Almagest*, Sirius is described as a red star, and there is no explanation on modern astrophysical grounds for such obvious disagreement.

BEHAVIOR OF MARINE ANIMALS

Volumes 5 & 6

SHOREBIRDS

edited by **Joanna Burger**, *Rutgers University*, and **Bori Olla**, *Oregon State University, Newport*

Volume 5

Breeding Behavior and Populations

The first volume of this outstanding two-volume set is a selection of current research in shorebird classification and breeding behavior: breeding site fidelity; polyandrous mating systems; communication; parental and antipredator behavior.
0-306-41590-9/454 pp./ill./1984
$59.50 ($71.40 outside US & Canada)

Volume 6

Migration and Foraging Behavior

This second volume covers behavior aspects during the nonbreeding season, focusing on abiotic factors affecting migration, migratory behavior in the Western Palearctic and New World, foraging and activity patterns, food supplies, and spacing patterns of nonbreeding migrants.
0-306-41591-7/344 pp./ill./1984
$49.50 ($59.40 outside US & Canada)

two-volume set: $89.50 ($107.40 outside US & Canada)

SYNTHETIC ORGANIC PHOTOCHEMISTRY

edited by **William M. Horspool**,
The University of Dundee, UK

This brand-new volume provides a broadly based account of the exciting opportunities arising from the application of photochemical methods in organic synthesis. Highlighting the synthetic value of the reactions discussed, the book deals with aromatic compounds, enones, electron-transfer reactions, phthalimides, heterocycles, azirines, photo-protecting groups, and oxetan formation and gives a brief outline of equipment and techniques.
0-306-41449-X/552 pp./ill./1984
$75.00 ($90.00 outside US & Canada)
Circle No. on Reader Service Card.

THE PHYSICIAN'S GUIDE TO DIVING MEDICINE

edited by **Charles W. Shilling, Catherine B. Carlston,** and **Rosemary A. Mathias,**
Undersea Medical Society, Bethesda, Md.

A practitioner's guide to the medical care of scuba divers and others who are exposed to hyperbaric environments. Covers physical, physiological, and behavioral effects of diving; diving equipment and procedures; how to diagnose and treat decompression sickness, gas embolism, and near-drowning; medical examination and evaluation of divers; and investigation of diving accidents.
0-306-41428-7/721 pp. + index/ill.
1984/$95.00 ($114.00 outside US & Canada)
Circle No. on Reader Service Card.

HANDBOOK OF MENTAL ILLNESS IN THE MENTALLY RETARDED

edited by **Frank J. Menolascino** and **Jack A. Stark**, *University of Nebraska Medical Center, Omaha*

The movement to deinstitutionalize the mentally retarded has created new challenges for mental health professionals responsible for the care of the enormous number of citizens who are both mentally ill and mentally retarded. This book offers a variety of ways to effectively treat and manage these patients, including individual therapy, group therapy, vocational training, and psychopharmacological approaches.
0-306-41648-4/437 pp. + index/ill.
1984/$39.50 ($47.40 outside US & Canada)

Aeronomy of the Middle Atmosphere

Chemistry and Physics of the Stratosphere and Mesosphere

GUY BRASSEUR and SUSAN SOLOMON

1984, xvi + 441 pp.
Cloth Dfl. 120,–/US $ 44.00/£ 30.50
ISBN 90-277-1767-2
ATMOSPHERIC SCIENCES LIBRARY

Aeronomy of the Middle Atmosphere is a comprehensive review of the authors' understanding of the natural and anthropogenic processes that influence the chemical composition of the stratosphere and mesosphere. Thermal and photochemical aspects of radiation are discussed, as well as atmospheric transport, and ion and neutral chemistry. The important coupling mechanisms between radiation, transport, and chemistry are emphasized. This volume will be a useful text for graduate level courses in aeronomy, and a source and reference work for researchers in atmospheric chemistry and physics, meteorology, and environmental science.

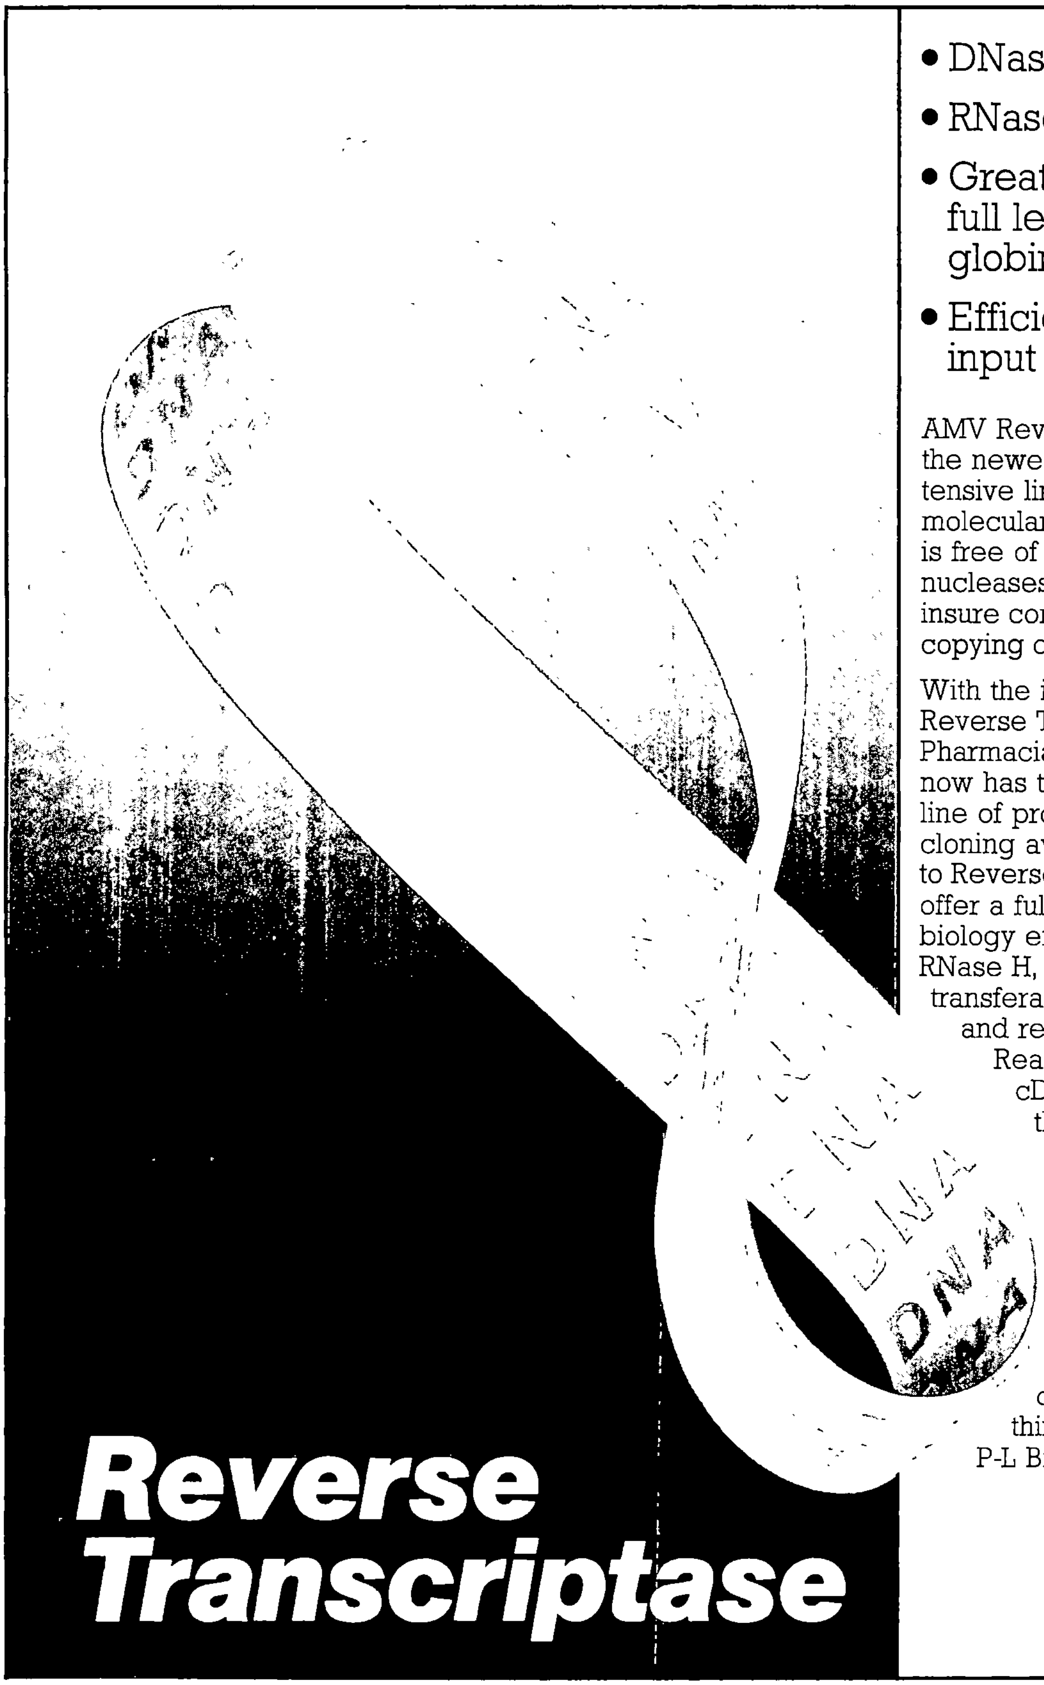
New from
Pharmacia P-L Biochemicals



- DNase free
- RNase free
- Greater than 90% full length globin transcripts
- Efficient copying of input mRNA

AMV Reverse Transcriptase is the newest addition to our extensive line of enzymes for molecular biology. The enzyme is free of all contaminating nucleases and is tested to insure complete and efficient copying of mRNA.

With the introduction of Reverse Transcriptase, Pharmacia P-L Biochemicals now has the most complete line of products for cDNA cloning available. In addition to Reverse Transcriptase, we offer a full line of molecular biology enzymes including RNase H, DNA ligase, terminal transferase, DNA polymerases and restriction nucleases. Ready-to-use vectors for cDNA cloning by either the Okayama-Berg or Heidecker-Messing cDNA cloning procedures are also available.

For Reverse Transcriptase and cDNA cloning, think of Pharmacia P-L Biochemicals!

Molecular biology and cancer

A Nature *conference next week is a modest celebration of the prospect that cancer will soon be understood. It does not imply that practical oncology will be transformed overnight.*

THE question whether molecular biology has a contribution to make to the practice of medicine has now been answered. And positively. The half-dozen or so techniques for the diagnosis of genetic conditions and infection which are already in the hands of physicians are a sufficient proof of that. But when will molecular biology contribute something important to the practice of medicine, perhaps by helping to cure a disease and not by merely recognizing it?

For the past few years, there has been widespread excitement over the opportunities which seem to lie ahead for the treatment of genetic diseases and, more immediately, for the understanding if not the treatment of some of the many different forms of human cancer, which are in part at least genetic aberrations. That is one of the reasons why *Nature* is next week holding a conference on the subject in Boston, Massachusetts.

The opportunities in the field of cancer for molecular biologists are literally fascinating. They do cast a spell as can be told from the now wide currency of the word *oncogene*, which almost everybody knows of — and misuses. And there is a general opinion that oncogenes have something to do with viruses, whence the somewhat chilling suspicion that some forms of human cancer may yet turn out to be infectious (as, indeed, it seems that adult T-cell leukaemia is, at least in the coastal regions of southern Japan).

At times like these, it is therefore important to remember how long and tortuous is the history of the field that now seems so full of promise. It is well over half a century since the late Dr Peyton Rous, then a young man, first claimed that a sarcoma (in chickens) could be caused by a transmissible agent, an old-fashioned synonym for a virus. Rous persisted in the face of the sceptical politeness owed such a modest man and was rewarded, although not vindicated, by Richard Shope's discovery of the cell-transforming papilloma virus in the early 1930s. Only with development of techniques in the post-war decades was the reality of oncogenic viruses proved up to the hilt, first in rodents with polyoma (a DNA virus), then with the subset of the RNA viruses (collectively known as retroviruses) shown to cause cancer in animals.

More recently, the possibility of a connection between the retroviruses and the causation of human cancer has been answered with yes and no in an illuminating way. The recognition within the past decade that there is often a close similarity between the nucleotide sequence of oncogenic retroviruses and certain unidentified genes in vertebrate cells was naturally a stimulus to investigation. Just over two years ago, three separate groups in the United States were able to show that a close similarity existed between the genetic structure of one strain of the ras retrovirus and a genetic structure in the DNA of cells taken from human bladder carcinomas.

By November of that year, two separate groups in the United States (at the Massachusetts Institute of Technology and at the National Institutes of Health) had been able to show that the aberrant structure, apparently that responsible for the causation of cancer, differed from that of a gene normally present in all human cells in apparently trivial ways. The normal version of the gene carries the code for a protein, called p21, whose existence had already been catalogued but whose function was unknown. The abnormal version of the protein, inferred from the structure of the abnormal gene, differs in only two amino acids in the sequence. From that point on, the attention of molecular biologists has been directed squarely at the human (and vertebrate) genome.

The picture that has emerged illustrates why the term oncogene is so commonly misused. At least in the case of the human bladder cancer (but probably many others), there is a normal gene which plays a crucial part in the biochemistry of all normal cells, and an aberrant version associated with the cancer. Strictly speaking, only the aberrant version deserves to be called an oncogene. In a careful world, the normal version would be called by a name indicative of its function.

So great has been the excitement since November 1982, that *Nature*, in a leading article on the outlook for 1983, offered the prospect that the causation of at least some forms of cancer would be understood within the year. In retrospect, that hope was over-optimistic; the function of p21 and its aberrant form have been glimpsed only in the past few weeks (see *Nature* 23 August, p.628, and references therein). But there have been other remarkable developments to make up for such disappointments as there may have been — the recognition that the oncogene called *myc* does appear to migrate from one chromosome to another in cases of human leukaemia and the startling recognition of a similarity of structure of the gene responsible for the normal receptor for human epidermal growth factor and a true oncogene carried by the retrovirus known as erb-B. Whether the laboratory and clinical versions of the aberrant gene also interact with the biochemical system involving p21 remains to be determined, but it is hard to suppress the suspicion that the time is fast approaching when it will be worked out which properties of the cell surface have gone awry in cases of human malignancy.

These are only some of the reasons why the present is a time for modest celebration. But even now, it is far from self-evident that a better understanding of malignancy will help with the treatment of the human disease. That is a question that physicians rightly ask. They do so in the knowledge that even now, in other fields of human therapy, the development of successful drugs has ridden on the back of an understanding of how a disease is caused biochemically. It is only a hope that the field of cancer may be different, or that, say, the new techniques of molecular biology will provide a full understanding of the mechanism by which cells acquire genetic resistance to cytotoxic drugs.

The long history of people's attempts to deal with human cancer counsels caution. There have been too many crude disappointments for any other course to be safe. But even if the only certainty is that there will soon be a rounded understanding of the processes leading to overt disease, and ultimately perhaps of the interaction between genetic and environmental influences, it should at least be possible to put present strategies for the avoidance of cancer on a much sounder footing.

The role of *Nature* in such developments should not be misunderstood. Even a journal which enjoys the privilege of publishing many of the most important discoveries in such a field is not a scientific society in the strict sense but a vehicle for communication among active investigators and between them and the wider body of professional people. But the process of communication, in this field just as in any other, is more than the mere publication of information. The sense of excitement shared by those working in a promising field is also relevant. And there is much value in a forum in which those working at the bench can meet those whose work may be affected by what emerges. That is the spirit in which this conference has been designed.

John Maddox

Nitrogen cycle

Nitrate leaching from grassland

from R.E. White

RECENTLY, interest has revived in the effect that nitrate leached from agricultural land may have on the quality of surface and underground water used for human consumption. The consensus of scientific opinion, as presented in The Royal Society Study Group's report 'The nitrogen cycle of the United Kingdom', published in December 1983, is that most of the nitrate leached comes from arable land and represents approximately one-third of the nitrogen (N) applied annually to that land as fertilizer. The report concludes that little of the 900,000 tonnes of fertilizer N spread on grassland is leached out of the root zone. By contrast, results published in *Nature* this week (page 50), from J.C. Ryden, P.R. Ball and E.A. Garwood of the Grassland Research Institute at Hurley, suggest that loss of nitrate by leaching from intensively-managed grazed grassland may be five to six times higher than losses from comparable swards cut for hay or silage. The average annual loss from the grazed sward was 162 kg N per ha, which exceeded by far the range of 52–93 kg N per ha per year quoted in The Royal Society report for nitrate leached from arable land into the unsaturated zone of Chalk aquifers.

The Hurley researchers took soil and subsoil samples at 0.33 m intervals to a depth of 8 m from two adjacent plots (0.123 ha) on a loamy soil of the Frilsham series on Upper Chalk near Hurley. Both plots were sown to perennial ryegrass in the year April 1976 to March 1977 and fertilized with ammonium nitrate at the rate of 420 kg N per ha per year between April 1977 and December 1982. The 'cut' sward was mown every 4 weeks during the growing season while the 'grazed' sward was stocked with yearling steers for 1 week in 4 at an average stocking rate of 9.3 head per ha. From measurements of the drainage rate of nearby lysimeters, it was estimated that percolating water from the drainage season immediately following 1976–77 should have reached a depth of 5.5–5.8 m by December 1982. This coincided very closely with the depth of 6 m at which nitrate concentrations in the soil water below the cut and grazed swards were not significantly different. Above that depth, nitrate concentrations under the cut sward ranged from 5.4 to 13.3 mg N per litre, whereas the concentrations beneath the grazed sward exceeded the 'acceptable' range of 11.3–22.6 mg N per litre set by the World Health Organization.

Following the December 1982 sampling, the swards were ploughed and cropped to spring barley and winter wheat. A further sampling to 3 m depth in December 1983 confirmed the pronounced mineralization of soil organic N that occurs when grassland is ploughed. Allowing for the 80 kg per ha of fertilizer N applied in 1983, some 275–310 kg per ha of N in excess of crop requirements were mineralized, most of it being nitrified and therefore vulnerable to leaching.

Ryden and co-workers attribute the greater loss of N from the grazed sward to the inefficiency of ruminant animals in converting fertilizer N to protein, less than 20 per cent of the N input to grassland being recovered in animal products. The return of much of the ingested N in dung and urine creates 'hot spots' in the soil where the uptake of N by the grass fails to match the supply. The excess mineral N is then vulnerable to leaching.

The results of the new study are especially interesting because most previous work has been done on cut swards exposed to smaller amounts of N fertilizer (<250 kg N per ha per year). The Royal Society report makes passing reference to nitrate concentrations of 10–100 mg N per litre in profiles beneath grass receiving >400 kg N per ha per year, but adheres to the central view that nitrate concentrations in water percolating below grassland are generally < 10 mg N per litre. Even so, much of the drainage water from less heavily-fertilized grassland will exceed the new European Community guide level of 5.7 mg N per litre. Grazing and fertilizer combined are likely to push the average concentrations above the new maximum level of 11.3 mg N per litre. As Ryden *et al.* point out, 37 per cent of the grassland of England and Wales now receives >200 kg N per ha per year and 5 per cent receives >400 kg N per ha per year. Further intensification of livestock farming is therefore likely to exacerbate the problem of nitrate pollution of water supplies at a time when politicians and the public are becoming more concerned about the potential health hazard of high nitrate in drinking water. □

Astrophysics

Galaxies in collision

from M.G. Edmunds

GRAVITY never fails to suprise. The exotic predictions of general relativity have perhaps rather overshadowed the quite remarkable effects that can occur with nothing more than simple inverse square Newtonian force. Interesting things happen when galaxies collide, and recent dynamical simulations suggest that some quite strange morphological features of galaxies can be attributed simply to gravitational interaction.

The discovery of 'shells' — sharply defined extended arcs of low brightness — around elliptical galaxies was first reported in *Nature* four years ago (ref. 1 and see Fig. 1). The features were so unexpected that at first sight it seemed that they must be some kind of false diffraction image. Familiar artefacts of this type are the spikes seen on photographs around the images of bright stars, caused by diffraction at the structural supports of the telescope's prime focus. Nevertheless, investigations using different telescopes and of many galaxies have shown that the shells are real and occur around about 11 per cent of elliptical galaxies. No spiral galaxy has so far been found to have them.

The shells are generally aligned with the major axis of the galaxy, but do not completely surround it. Around a single galaxy there can be up to twenty shells, ranging over a factor of 30 in radius. Particularly intriguing is the observation that where several shells occur, they are generally interleaved, such that the next shell out in radius from the centre is on the opposite side of the nucleus. The colours of the shells[2] are consistent with the colours of the population of stars in the galaxies, so it seems that the shells are composed of stars, though not particularly young ones.

How do stars come to be organized into such sharp-edged configurations? One possible explanation is that they formed there. Gas lost from stars in the main body of the galaxy[3] or from an active galactic nucleus[4] could blow out of the galaxy, cool and suddenly form into a narrow shell of stars as conditions became suitable. But why the regular spacing of multiple shells (unless it is the result of recurrent events) and, even more strange, why the alternation of shells on either side of the galaxy? An argument against the suggestion of an active nucleus is that the galaxies with shells seem, on average, to show radio emission less often than do similar galaxies without shells.

An explanation of shells on purely dynamical grounds[5] was examined by P.J. Quinn (formerly of the Australian National University and now at Caltech) in his thesis work, and has now been published[6]. The basic idea is that a disc galaxy collides with a very much more massive — perhaps by a factor of 10 or 100 — elliptical galaxy. The massive elliptical acts as a potential well in which the stars from the disc become trapped. Computer simulations, performed with certain simplifying assumptions, show that the

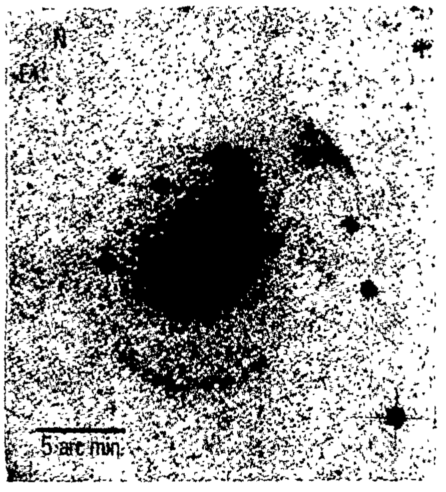

Fig. 1 The elliptical galaxy NGC 1344, showing sharp-edged shells which may be the result of gravitational interactions in a galactic collision (UK Schmidt plate, from ref. 1).

disc breaks up and the stars oscillate around in the potential. Provided the collision parameters are set correctly, and provided the original disc was dynamically 'cold' (did not have much random motion in the stars), then shell-like structures do occur. The number of stars per unit volume inside a galaxy is in general far too small for actual physical impact of the stars — they merely pass by each other and scatter off the gravitational potential of the system. The stars from the ruptured disc spend a lot of time at the ends of the radial motion of their orbits — rather as a simple harmonic oscillating pendulum spends most of its time at the ends of its swing — and the bunching of stellar orbits there is visible as a shell. The orbits evolve with time and more shells (essentially density waves) appear, interlaced on opposite sides of the centre, as is observed. The lifetime of a shell system, which ends when its structure becomes washed out by internal velocity dispersion, is predicted from these models to be some 2×10^9 years from the collision, during which time 10 - 30 shells would appear.

Astronomy still has a skeleton, not merely in its closet but actually knocking at the closet door, in the form of non-luminous mass in and around galaxies which we know must exist but cannot see. If correct, this gravitational-interaction picture could provide a most useful means of approaching the problem. Since the spacings of the time-evolving shells depend on the form of the gravitational potential, they can be used to probe the total (seen and unseen) mass distribution of the elliptical.

Despite their apparent success, Quinn's models face two major problems. The first is observational, the second theoretical. It might be expected that shell galaxies would occur where there was opportunity for plenty of collisions, but the reverse is observed: galaxies with shells are found preferentially in regions of low space density of galaxies. This objection can be weakened slightly by claiming that in groups or clusters of galaxies, the velocities of collision would be too high for production of shells, or that subsequent collisions might destroy the shells.

The second, and probably more serious, problem is that shells are produced in the simulations only for a rather restricted type of collision. As Quinn is at pains to point out, other collision conditions lead to a veritable Modern Art gallery of structures. In a classic investigation some years ago[7], Toomre and Toomre showed that the tidal gravitational interaction between two galaxies could lead to very peculiar structures — filaments, jets, arcs, bridges and tails — composed simply of stars pulled out in the collision. But in ellipticals, regular shell structure is found far more frequently than the complex structures that might be expected to result from arbitrary collision parameters. Undoubtedly some very strange structures do exist; sensitive photographic techniques and electronic light-sensitive arrays are beginning to reveal increasing numbers of jet-like structures in both spiral and elliptical galaxies. Just how many features can be accounted for on the basis of gravitational tidal interaction remains to be seen. Much more work can be done on dynamical simulations, although the almost unlimited range of masses, potentials, relative velocity vectors and internal dynamical states of the colliding galaxies makes this approach rather open-ended. Quinn's use of a fixed potential for the more massive galaxy must inevitably have suppressed collective effects — although it was sensible for computational convenience in an initial investigation.

The effects of collision on spiral galaxies have also been the focus of attention, with recent accurate mapping of the velocity field of a 'ring' galaxy in the direction of the Vela constellation by Taylor and Atherton[8]. Ring galaxies are fairly rare structures, characterized by a bright annulus, typically of young stars and associated glowing gas (Fig. 2). Two rival schemes have been put forward to explain their origins. Both explanations involve a normal spiral galaxy, with one scheme requiring collision with an intergalactic gas cloud, and the other collision with an elliptical (by contrast with the mechanism of shell formation, in the scheme for forming ring galaxies, the elliptical is much smaller than the disc galaxy). The critical ingredient is the gas, which is physically shocked and much of it forced over into gravitational collapse to form new stars.

The new velocity data, obtained with the novel 'Taurus' imaging Fabry–Perot system on the Anglo-Australian Telescope, are rather ambiguous. The velocity field is not what would be predicted in a head-on collision with an elliptical, that is, an expanding rotating ring. It may well be that the ring is actually folded back on itself, which could occur in collision with a gas cloud, as has previously been suspected in another peculiar galaxy, Arp 144. The main difficulty, though, is that there are not enough intergalactic gas clouds to produce even the small number of ring galaxies known. Taylor and Atherton hedge their bets, and suggest both schemes may produce a share of the objects.

Colliding galaxies certainly seem to be coming back into vogue. Back in the 1950s, Baade and Minkowski proposed galactic collisions as the origin of strong radio sources. Although now it is massive black holes in galactic nuclei that are the preferred power source, it is becoming popular to attribute enhanced activity to the effects of collisions spilling fresh gaseous fuel down into the nuclei. The sudden 'starburst' of star formation that is induced by collision in the presence of a large amount of gas will in itself generate significant radio emission from new supernovae remnants. If there is a large amount of dust as well, absorption of visible and ultraviolet radiation and its re-emission at infrared wavelengths may give rise to the very strong infrared luminosities (up to 100 times the optical output) detected by the IRAS satellite in several apparently interacting systems. Infrared excesses from interacting pairs, seen in ground-based studies[9], suggest that only one of the pair undergoes a sudden starburst.

Fig. 2 The Cartwheel galaxy, a giant ring galaxy, which may have been formed by collision. (Photograph by Photolabs, ROE, from an original negative by the UK 1.2 m Schmidt telescope.)

A new catalogue[10] of elliptical galaxies with shells has been prepared by the original discoverers, D.F. Malin and D. Carter, and contains over 130 candidates for further study. What an exciting prospect, given the rich diversity of complicated structures that can be generated by a low-velocity galactic collision. !

MICRO-84

Electron microscopy 50 years on

from Colin J. Humphreys

IN 1934, *Nature* published the first electron micrographs of biological material. Fifty years later, the Royal Microscopical Society, in association with *Nature*, organized MICRO-84, an international microscopy conference and exhibition held in London from 9 to 13 July 1984. The conference was attended by about 800 scientists from all over the world.

One of the highlights of the meeting was a description by Albert Crewe (University of Chicago) of a revolutionary 0.6 Å point resolution scanning transmission electron microscope he has recently started to build. This represents a dramatic advance in resolution over existing electron microscopes, the best of which have a point resolution of about 1.7 Å. Modern electron microscopes have computer control added on, as it were. Crewe proposes to reverse this procedure and build his microscope around a computer system large enough to operate and control the microscope, and process and store the images. His computer system, comprising four computers with 3.6 Giga bytes of storage, has been donated by IBM, which demonstrates the importance that major microelectronics companies attach to high-resolution electron microscopy. If successfully built, Crewe's microscope should have major applications in biology, chemistry, materials science and physics.

Many microelectronic circuits are now so small that they cannot be resolved using an optical microscope, and an electron microscope is necessary simply to see them. D. Cherns (University of Bristol) and W.M. Stobbs and D.J. Smith (University of Cambridge) demonstrated how high-resolution electron microscopy can be used to determine the positions of atoms lying in and near the interfaces of semiconductor devices, so that their electrical properties can be understood.

In recent years, not only the resolution but also the analytical capabilities of electron microscopes have dramatically improved. It is now possible to analyse chemically very small regions of materials using an electron beam less than 10 Å in diameter, by detecting the signals (for example, characteristic X rays) generated when the incident electron beam is inelastically scattered by the specimen. Moreover, it is possible to measure the energy spectrum of the transmitted electrons by a technique called electron energy loss spectroscopy, which is sensitive to all elements and is increasingly being used for the analysis of both biological and non-biological materials.

If the fine structure of an electron energy spectrum is studied, a technique known as electron loss near edge structure (ELNES), results can be obtained equivalent to those achieved on a synchrotron source, but for any atomic number element and with far higher spatial resolution (C. Colliex, University of Paris). ELNES tells us not only what atoms are present in a sample, but also their environment. Mick Brown (University of Cambridge) described some novel applications of electron energy loss spectroscopy which exploit the very high spatial resolution available, for example, the measurement of energy band gaps in insulators.

Topics covered in the wide-ranging programme included microsurgery, forensic science, archaeology and art. Among the relatively new fields, C.F. Quate (Stanford University) gave an outstanding review of the advances in acoustic microscopy from a resolution of 10 µm 10 years ago to one of 300 Å, using helium, today, and G. Schmahl (University of Göttingen) described the latest results from his 500 Å resolution X-ray microscope, which is probably the best in the world. X-ray microscopy offers the prospect of studying living biological material with a resolution far better than that of optical microscopy, and with much less damage than is produced in an electron microscope. To be really useful, however, its resolution will have to be improved still further. Perhaps this will be achieved by the next meeting of MICRO, in 2 years time. ☐

Vaccine development

Recombinant vaccinia for prevention of hepatitis B

from John Beale

THE idea of using vaccinia virus as a means of carrying other immunogens for the purpose of vaccination has seemed very attractive since Paoletti and Moss and their colleagues started to investigate the use of vaccinia recombinants in 1982 (Panicali, D. & Paoletti, E. *Proc. natn. Acad. Sci. U.S.A.* **79**, 4927; 1982 and Mackett, M., Smith, G.L. & Moss, B. *op. cit.* **79**, 7415; 1982). The rationale is that the live virus will express a foreign gene inserted into its DNA when it is applied to an animal, which will subsequently produce an immunological response to the foreign gene product. So far, recombinant DNA technology has been used successfully to express various antigens in vaccinia, including hepatitis B virus surface antigen (HBsAg), malaria sporozoite antigen, and influenza and herpes glycoproteins, and the list is growing all the time. On page 67 of this week's *Nature*, Moss and his colleagues take the hepatitis story a stage closer to a practical vaccine by showing that chimpanzees can be protected against hepatitis by vaccination with live recombinant vaccinia virus.

Last year, Smith, Mackett and Moss reported the construction of a fusion gene between DNA encoding HBsAg and an early vaccinia promoter (*UCLA Symp. molec. cell. Biol.*, New Ser. **8**, 543; 1983). By inserting the fusion product into the thymidine kinase-encoding portion of the vaccinia genome such that thymidine kinase activity was no longer expressed, they could select the new recombinant virus by growth in the presence of 5-bromodeoxyuridine. The plaques were tested for HBsAg expression by dot-blot hybridization and for HBsAg gene expression by immunological methods.

What Moss and his colleagues have now done is to vaccinate two chimpanzees with the HBsAg-containing recombinant vaccinia virus and one chimpanzee with wild-type normal vaccinia virus, and then challenge them with living hepatitis B virus. They find that treatment with HBsAg–vaccinia hybrids produces smaller lesions and lower antibody titres to vaccinia than does treatment with vaccinia alone. None of the animals produced antibodies to HBsAg after vaccination. On challenge with hepatitis B virus, however, the chimpanzee given vaccinia alone developed typical signs of hepatitis B virus infection: hepatitis surface antigenaemia, antibodies to the core antigen as well as to the surface antigen of hepatitis B (the production of core antibodies indicates some hepatitis B virus replication had occurred in the primed animal) and biochemical evidence of hepatitis. By contrast, the two HBsAg–vaccinia-treated chimpanzees, although producing no antibodies before challenge, were protected against the challenge, as shown by the lack of biochemical evidence of liver damage and of antigenaemia, and the rapid onset of antibodies to the surface antigen. They had thus been immunologically primed by the expression of HBsAg when the recombinant vaccinia was growing in the skin.

These are impressive results that pose in a sharper form the policy implications of this approach. The attraction is that the accepted and proven instrument of smallpox eradication can be adapted to the formidable task of hepatitis B prevention.

Indeed, as a result of the success of the World Health Organisation (WHO) smallpox eradication campaign, vaccinia has had magical powers conferred on it, not only by the populations that have benefitted; but also by some public health officials.

At the time of the first publication by Smith, Mackett and Moss, two problems were foreseen: immunity to vaccinia and the question of safety. These two issues remain. On any rational consideration of cost versus benefit, vaccinia should be acceptable in Third World countries for the prevention of hepatitis B. Such decisions are not always made rationally, however, and the use of a vaccinia hybrid for the control of hepatitis B in the USA, for example, would probably be more convincing to governments in Third World countries than hours of debate. For western countries, however, there is no incentive to use vaccinia with its known hazards, which caused it to be abandoned for smallpox control around the time that the WHO started its smallpox eradication scheme. Moss *et al.*'s finding that the lesions in the chimpanzees were less for the recombinant than for the wild vaccinia is encouraging, although more work is clearly needed. The problems of effectiveness and of interference from vaccinia antibodies during booster doses remain to be overcome.

As large amounts of hepatitis B surface antigens become available using recombinant DNA techniques of expression in yeasts and in mammalian cells, there may be no need to use a vaccinia carrier. Instead, it may be possible to combine hepatitis B vaccine with other nonliving childhood vaccines, and to give the combination at birth or soon thereafter.

Priming of the immune response so that immunological memory is induced is one aim of a vaccination programme. Recently, Salk *et al.* (*Ann. clin. Res.* **14**, 204 ; 1982) have argued forcibly that this would justify consideration of a single dose of killed poliovaccine for poliomyelitis control in tropical areas. The problem is the uncertain duration of memory in the absence of an adequate primary stimulus to produce antibody of both IgM and IgG classes. Further experimental data should soon be available to answer these outstanding questions for poliovaccine.

As to future research into the use of vaccinia as a carrier of immunogens, increased expression of the inserted DNA so that larger quantities of immunogen are produced is an important goal. Certainly, there is sufficient evidence to warrant continued research and the cautious extension of experiments in man. It is, however, much too early to think this promising line of research is a panacea for all the vaccine problems in developing countries. ☐

Mathematical modelling

The cubic map in theory and practice

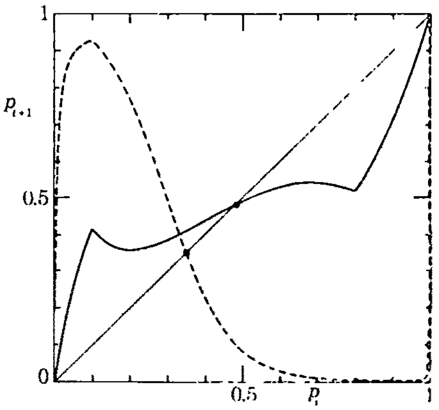
from Robert M. May

FOR many populations of temperate-zone insects, the adults emerge, mate, reproduce and die over a brief interval in the summer. The dynamical behaviour of such a population, with discrete nonoverlapping generations, may be described by a first-order difference equation of the form $x_{t+1} = f(x_t)$; the population density in generation $t + 1$, x_{t+1}, is given as some function, f, of the density in generation t, x_t. If this equation were linear ($f = \lambda x$), the population would simply increase (or decrease if $\lambda < 1$) in familiar exponential fashion. More commonly, however, the population will tend to increase when at low densities and to crash at high densities, corresponding to some non-linear function or 'map' with a hump (of which the quadratic $f = \lambda x(1-x)$ is the mathematically simplest example). It is now widely appreciated that such non-linear first-order difference equations with a single hump or critical point can unfold an astonishing richness of dynamical behaviour: as nonlinearities become more severe (specifically, as λ increases in the quadratic example), the original stable point gives way to a cascade of period-doubling bifurcations, successively producing cycles of periods 2, 4, 8, 16, ..., 2^n; eventually an apparently 'chaotic' regime is entered, in which the trajectories generated by this deterministic process can be effectively indistinguishable from random noise[1,2]. Many features of this bifurcation phenomenon are reproduced in a self-similar manner, on even finer scales, in successive period doublings, in ways that are generic to essentially all maps with one critical point[1-3]. This subject, which first came to prominence in the early 1970s in studies of biological populations[4,5], has grown dramatically as more possible applications are found in the physical and engineering sciences.

What are the properties of maps with two humps? The canonical example of a map with two critical points is the symmetrical cubic $x_{t+1} = \lambda x_t + (1-\lambda)x_t^3$ (which is chosen such that + 1 maps to + 1, 0 to 0 and −1 to −1). A hint that the dynamics of the cubic are likely to be messier than those of the quadratic is provided by a theorem saying that maps with n critical points can have up to n distinct stable orbits for any given set of parameter values[6]. For maps with one hump, this means at most one stable state or attractor; for generically cubic maps, however, there can be two alternative attractors. Several authors have set out how two such alternative stable orbits can arise for the cubic map[7-9]: when the originally stable point at $x = 0$ becomes unstable (for $\lambda > 2$), it first bifurcates to give a single symmetrical cycle with period 2; as the map becomes more significantly nonlinear ($\lambda > 3$), this cycle does not bifurcate to give a 4-cycle, but rather splits to give two distinctly different (and unsymmetrical) 2-point cycles. Each of the separate 2-point cycles then unfolds the familiar cascade of period doublings to cycles with periods 4, 8, 16, ..., 2^n as λ continues to increase. These cascades display the self-similar properties emphasized by Feigenbaum[3] for the quadratic map. For yet larger values of λ we enter the apparently 'chaotic' regime, where, again, there are two separate attractors for most values of λ. A detailed catalogue of all the possible cycles that lurk as a kind of kaleidoscopic fine structure within the apparently chaotic regime is much more complicated than for the quadratic map[1,2], though an explicit such catalogue has been given for all cycles with periods up to 10, in their order of appearance[9]. Methods for computing the total number of distinct cycles with period k have also been given[7].

The motive behind the first studies of the cubic map was simply that it represented the next logical step beyond the quadratic[7]. Since then, however, the cubic map has come to people's attention in a variety of practical contexts.

Holmes[10] studied equations that arise as the simplest description of a buckled beam that is subjected to forced lateral vibrations. This led him naturally to consider the cubic equation given above, as being the simplest dynamical relationship satisfying the symmetry requirements of his problem. Holmes then established that, for a wide



Relationship between the frequency of allele A in successive generations, p_{t+1} to p_t, for a system in which the fitness of host genotypes are determined by associations with pathogens. It is the general propensity to increase at low values and decrease at high values that is the characteristic of the cubic map. (From ref. 16.)

range of parameter values, "two distinct non-periodic attractors exist". His numerical studies of the more complicated buckled beam problem — using both a digital and an analogue computer — corroborated that, indeed, two distinct attracting states exist.

Perez, Jeffries and Testa[11] have experimented with an electronic circuit consisting of a harmonically driven *p–n* junction. They find this system to be characterized by period doublings and chaos of a kind that cannot be modelled by a map with one critical point. Guided by the numerical studies of Testa and Held[8], they believe the symmetric cubic map may describe the essentials of their observations. Perez *et al.* also discuss similar dynamical phenomena, again possibly corresponding to a cubic map, arising in the Belousov–Zhabotinsky chemical reaction.

More generally, Pikovsky[12] has observed that the dynamical properties exhibited by the cubic map may help explain the kinds of transitions to chaos that are observed in systems with a particular symmetry: an example could be the transition to turbulence in a hydrodynamic system with symmetrical boundary conditions. An independent and more explicit example of this sort is provided by Coste and Peyraud's[13] study of the Poincare map generated by a model for Rayleigh–Benard convection. For this symmetrical system, these authors find a bifurcation sequence of the kind described for the cubic equation above (and elsewhere they give an independent analysis of the bifurcation structure of the cubic map[14]).

To my mind, the most interesting application of the cubic map and its friends and relatives with two critical points lies in population genetics. In many situations, it can be that rarer genotypes — and hence rarer alleles — enjoy a selective advantage in the natural world. When this happens, the frequency, p, of the allele A at a diallelic locus will tend to increase when it is rare, and to decrease when the allele is common; that is, the map expressing p_{t+1} as a function of p_t will tend to have two humps. If the frequency-dependent effects are exactly symmetrical, we will have the symmetrical cubic map discussed above, and more generally we will have some unsymmetrical map with two critical points. The ensuing frequency of the allele A may settle to a stable constant value ('balanced polymorphism'), or it may oscillate (in a unique cycle, or in one of two alternative cycles), or we may have apparently chaotic dynamics.

Hamilton[15] has observed that the selective forces exerted by pathogens on their host genotypes are likely to be of just this frequency-dependent kind, with rarer genotypes being at an advantage because their particular diseases are less effectively transmitted by virtue of their low host densities. Hence host-parasite evolution may produce cyclic or chaotic variation in the prevailing host genotype from generation to generation. Hamilton goes further to observe that sexually recombining host populations will undergo less severe oscillations or chaos than corresponding asexual ones, essentially because the existence of heterozygotes and of crossing-over in multilocus situations endows the sexual system with greater dynamical inertia than the asexual one. It can then be that, under strong frequency-dependent selection of the kind possibly associated with pathogens, sexual systems enjoy an average fitness more than twice that of the corresponding asexual system, due to this dynamical mechanism. (The detailed argument is complex, but I believe the basic mechanism is as set out here.) Hamilton's calculations use plausible phenomenological expressions for the frequency-dependence in host fitness produced by pathogens; later studies employing epidemiologically-derived fitness functions find that sexual systems can overcome their intrinsic twofold disadvantage only in the most exceptional circumstances, which tends to undercut the theoretical basis for the suggestion that parasites are responsible for the evolution and maintenance of sex[16]. The idea, however, remains a fascinating one, and it will ultimately stand or fall on the basis of empirical tests of its predictions, several of which are underway[17-19]. Courting couples may feel that sex and the cubic map have little in common, but the fact remains that these two topics are intimately linked in current research on population genetics. ☐

Atmospheric chemistry

Ozone increases in ground-level European air

from S.A. Penkett

EPISODES of photochemically generated ozone are now a common form of acute air pollution in Europe, whilst smoke fogs, which were typical of winter in London and other cities in the 1950s, have largely disappeared. The reasons are complex and are concerned with the changing emission patterns of primary pollutants and with the chemical changes that occur in the atmosphere. High ozone concentrations caused by photochemical pollution were first detected in Los Angeles in the 1940s. It was not until more than twenty years later that the first indications were found of a similar problem in Europe. Measurements of ground-level ozone then commenced, in Holland and at Harwell in southern England. These have produced clear evidence of the production of large amounts of ozone at ground level under anticyclonic conditions.

It is unfortunate that ozone measurements in western Europe started only recently, because it is difficult to detect a trend. By contrast, systematic measurements have been made at both urban and rural sites in the German Democratic Republic (GDR) since 1952. The results show a dramatic increase in the yearly average ozone concentration with the largest increase being observed at rural sites. Data from five sites located throughout the GDR were published in 1979 but attracted little attention at the time (Warmbt, W. *Z.Met.* **29**, no.1, 24; 1979). Recent interest in ozone as a possible cause of damage to forests has highlighted the importance of this unique data set.

The measurements were made using the classical technique of iodometry in solution, which is subject to interference from other atmospheric gases. Modern methods of ozone measurement utilize an absolute optical absorption method to avoid these problems. The same technique was used consistently in the GDR measurements, however, and the imperfections were recognized. Interference from sulphur dioxide was particularly bad at urban sites until a chemical filter was introduced in 1972. At rural sites the interference was less and at one site, Cape Arkona on the Baltic Coast, it was totally absent.

The average ground-level ozone concentration at Cape Arkona showed an increase in the yearly mean from ~ 15 parts per 10^9 by volume (p.p.b.v.) in 1956 to ~ 24 p.p.b.v. in 1977, the most recent year for which data are reported. The mean summer ozone concentration almost doubled, from ~ 18 p.p.b.v. to ~ 32 p.p.b.v. over the 21 year period. The maximum levels observed in photochemical episodes were considerably greater, reaching values of over 100 p.p.b.v.

There are no other ground-level observations of ozone in Europe going back so far. Nevertheless, data collected on the Hohenpeissenberg in southern FRG from 1971 to 1976 show a similar trend to those from the nearest GDR station over the same period. Probably the most numerous data for Western Europe have been collected in Holland. These measurements started in 1969 but are mostly urban and will be affected by large emissions of nitric oxide in the immediate vicinity. This gas reacts rapidly with ozone with the result that levels in urban areas tend to be lower than those in rural areas. The Dutch data show no overall increase during the 1970s.

The continuous upward trend in ground-level ozone concentration, seen particularly at rural sites, is unlikely to be a result of increased transfer of ozone from the stratosphere, which provides much of the ozone in the troposphere, but rather of a change in the efficiency of production *in situ* in the boundary layer. Photochemical production of ozone in the lower atmosphere occurs through a complex chain reaction involving free radicals. The essential precursors are oxides of nitrogen and hydrocarbons; emissions of both these species in Europe have increased substantially over the period covered by the ozone data. If Britain is typical, nitrogen oxide emissions have increased by about 50 per cent and emissions of hydrocarbons have more than doubled. Motor vehicles are the largest source of the chemically reactive hydrocarbons that are the most effective in producing ozone, and between 1953 and 1975 fuel usage in Britain increased about threefold. Most of the increase occurred before 1970, during a time when no systematic measurements were made either of the primary pollutants or of their effects on the ozone concentration. This emphasizes the unique nature of the GDR data.

The observed increase in ozone is indicative of an increase in chemical reactivity in the atmosphere which will probably be reflected in an increased rate of acid production. Indeed, amounts of other potentially acid species may be correlated with ozone. For example, the nitrate content of atmospheric aerosol and of rainwater in England has increased roughly by a factor of three since the mid 1950s. The nitrate aerosol and ozone trends both show peaks and troughs which are associated with meteorological factors, in particular with the amount of sunlight. There is, in fact, some correlation between high oxidant levels and good vintage years, particularly for the Rhine and Mosel wines grown at a similar latitude to the stations where the data were collected. Clearly, there is a strong case for sustained research into the nature of all chemical changes in the atmosphere that lead to the formation of strong oxidants and free acidity. These two chemical properties are strongly linked, as the German word for oxygen, *sauerstoff* (literally 'acid stuff'), shows.

The known aspects of ozone chemistry in the troposphere have recently been discussed in the Swedish journal, *Ambio* (**13**, no.2, 61; 1984). The phytotoxic properties of ozone are emphasized, particularly in the context of forest damage in central Europe. The influence on climate of an increase in ozone concentration throughout the Northern Hemisphere is also considered, as it is possible that emissions of oxides of nitrogen and carbon compounds, such as carbon monoxide and hydrocarbons, from a variety of sources now affect the distribution of tropospheric ozone on a hemispheric scale. Thus, data from the global ozonesonde network show, for the period 1968–1979, an annual increase in ozone concentration of 1 per cent in the height range 2 – 8 km at mid latitudes in the Northern Hemisphere. Ozone behaves as a greenhouse gas, that is, it absorbs infrared radiation from the Earth's surface and thus acts as a thermal blanket. Calculations suggest that a doubling in the tropospheric ozone concentration will increase the global surface temperature by approximately 1°C; this is of a similar magnitude to the value of 3°C calculated for a doubling in the CO_2 concentration. □

THE TEMPERATURE OF THE SOLAR SURFACE

THE power developed by the sun motor, recorded in *Nature*, has established relations between diffusion and energy of solar radiation which prove that the temperature of the surface of the sun is extremely high. I have, therefore, during the summer solstice of 1884, carried out an experimental investigation for the purpose of demonstrating the temperature of the solar surface corresponding with the temperature transmitted to the sun motor. I have accordingly constructed an instrument of large dimensions, a polygonal reflector (see Fig. 1), composed of a series of inclined mirrors, and provided with a central heater of conical form, acted upon by the reflected radiation in such a manner that each point of its surface receives an equal amount of radiant heat in a given time. The said reflector is contained within two regular polygonal planes twelve inches apart, each having ninety-six sides, the perimeter of the upper plane corresponding with a circle of eight feet diameter, that of the lower plane being six feet. The corresponding sides of these planes are connected by flat taper mirrors composed of thin glass silvered on the outside. When the reflector faces the sun at right angles, each mirror interprets a pencil of rays of 32.61 square inches section, hence the entire reflecting surface receives the radiant heat of an annular sunbeam of 32.61 × 96 = 3130 square inches section. The reflector and conical heater are sustained by a flat hub and eight radial spokes bent upwards towards the ends at an angle of 45°. The heater is composed of rolled plate iron, and provided with head and bottom formed of non-conducting material. A short tube passes through the upper head of the heater, through which a thermometer is inserted for measuring the internal temperature. The stem being somewhat less than the bore of the tube, a small opening is formed by which the necessary equilibrium of pressure will be established with the external atmosphere. It should be mentioned that the indications of the thermometer during the experiment have been remarkably prompt.

The result of the experimental investigation carried out during the summer solstice of 1884 may be thus briefly stated. The diffusion of the solar rays acting on the 20-inch heater being in the ratio of 1 to 10,241, the temperature of the solar surface cannot be less than 298°.87 × 10,241 = 3,060,727° F. This underrated computation must be accepted unless it can be shown that the temperature produced by radiant heat is not inversely as the diffusion of the rays. Physicists who question the existence of such high solar temperature should bear in mind that in consequence of the great attraction of the solar mass, hydrogen on the sun's surface raised to a temperature of 4000°C., will be nearly twice as heavy as hydrogen on the surface of the earth at ordinary atmospheric temperatures; and that, owing to the immense depth of the solar atmosphere, its density would be so enormous at the stated low temperature that the observed rapid movements within the solar envelope could not possibly take place. These facts warrant the conclusion that the high temperature established by our investigation is requisite to prevent undue density of the solar atmosphere.

Polymer science

Novel helical conformation in a nylon

from Edward Atkins

X-RAY structure determinations undertaken so far on different nylons have shown that the chains crystallize in an extended planar zig-zag conformation. In the crystals, the vital amide groups (-NH-CO-) participate in interchain hydrogen-bonding in the plane of the zig-zag, generating hydrogen-bonded sheets which stack to form the three-dimensional crystalline structure. The properties and behaviour of the nylons examined until now all relate to this type of molecular architecture. In this issue of *Nature* (page 53), Fernández-Santin, Aymamí, Rodriguez-Galán, Muñoz-Guerra and Subirana describe a novel structure for a nylon derivative, poly(α-isobutil-L-aspartate) : a contracted spring-like helix, stabilized by intrachain hydrogen bonds, which exhibits a number of similarities with the well-known α-helix found in proteins and polypeptides (see Fig.3 on page 53). This novel spring-like conformation is of interest not only for its own sake and because of the implications it has for the properties of a nylon, but also because it highlights the link nylons can provide between synthetic polymers and proteins.

The nylons or polyamides represent a spectrum of synthetic polymers in which amide groups introduce a hydrogen-bonding capability into the structure. At one extreme, the amide groups occur very infrequently, and the nylons approach the conformation, behaviour and properties of polyethylene: an extended planar zig-zag chain associating with neighbouring chains through relatively weak van der Waals' interactions. Near the other end of the spectrum, where the amide groups are separated only by one or a few CH_2 units, is the structure, known as nylon-2, which is chemically identical to polyglycine — a polypeptide or simple protein — in which two carbon atoms ($-CH_2-CO-$) occur between successive nitrogen atoms in the chain. (The ultimate polyamide is nylon-1.) The bulk of the nylons used industrially have amide groups distributed with a frequency intermediate between these two extremes. A common polyamide is nylon-6 with six carbon atoms between successive nitrogens. It might be predicted, *a priori*, that as the frequency of amide groups increases and the nylons take on a similar chemistry to that of polypeptides and proteins, they would be capable of mimicking their biopolymeric counterparts.

In proteins, only a relatively small number of regular conformations have been found, of which the α-helix, the 3-fold or collagen-like helix and the β-sheet are the most prominent. These regular structures are ubiquitous in fibrous proteins (Fraser, R.D.B. & MacRae, T.P. *Conformation in Fibrous Proteins*, Academic, New York; 1973) and occur as domains, connected by less regular segments, in the convoluted conformations found in globular proteins, for example myoglobin, haemoglobin and the enzymes. β-sheets are extended protein chains, hydrogen-bonded together to form sheets. They occur in many insect silks, and can be thought of as the biopolymeric analogues to the traditional nylon structures. Unlike the β-structures, which are stabilized by interchain hydrogen-bonding, the α-helix is a contracted spring-like helix stabilized by intrachain hydrogen bonds, and is found in many keratinous tissues such as hair.

The novel structure discovered by Fernández-Satin *et al.* for nylon-3, which closely approaches the frequency of amide groups in proteins (variants of nylon-2 backbone), is a departure from the traditional nylon structures and represents the first of what is hoped to be a family of self-stabilized spring-like helices for nylons. These substances should exhibit behaviour and properties quite different from those of previous nylons, but similar to those of the extensively studied α-polypeptides and α-proteins. □

Anaesthesia

Glycine receptor protein the solution?

from W. Graham Richards

ALCOHOL added to a fish tank containing newts will anaesthetize the newts and they will keel over unconscious. Surprisingly, a subsequent increase of the hydrostatic pressure on the water of the tank reverses this anaesthesia and the unconscious creatures revive and will swim normally under the increased pressure. This is an example of the pressure-reversal of anaesthesia which is widely observed across a huge range of species and ought to provide some clue as to the mechanism of general anaesthesia. Work described in this issue of *Nature* (page 56) uses this approach and comes up with some intriguing results which may implicate glycine-mediated synaptic inhibition in the action of anaesthetics.

In pharmacological terms, general anaesthesia seems to be a rather crude affair not involving very specific molecular receptors: large concentrations of anaesthetic are used and almost any gas, even an inert gas such as helium, will act as an anaesthetic if applied at sufficient pressure. A vital practical ramification of this is the narcosis suffered by divers who can be made semiconscious as a result of the anaesthetic effects of nitrogen in air when they reach depths at which the anaesthetic pressure becomes significant.

The traditional interpretation of this lack of specificity and the influence of pressure has been that the effect of anaesthetic has a relatively simple physical origin. Since anaesthetic potency correlates with solubility in fat, it has been held that the results are achieved by solubility of the gas in lipid membranes; swelling produces anaesthesia reversible by compressing the membranes. Alternatively, the hydrophobic part of a specific protein could be the site of solution.

In this week's *Nature*, Smith *et al.* provide a significant step forwards in elucidating the mechanism of anaesthesia in more precise molecular terms. The key observation is a complete difference in response to pressure between anaesthetized tadpoles and shrimps with anaesthetics chloroform, ether, ethanol, halothane and sodium pentabarbitone. Thus, whereas the relative potencies of these anaesthetics in the two species are very similar, the influence of pressure is totally opposite in the two cases: shrimps show no sign of pressure-reversal, indeed pressure can potentiate anaesthesia, while in tadpoles, the effects of anaesthetic are reversed by the application of pressure in otherwise identical circumstances.

The authors' preferred explanation of this dramatic difference derives from the fact that crustaceans, such as the freshwater shrimp, have a nervous system which is insensitive to strychnine. This implies they do not use glycine as a neurotransmitter. Thus, it is possible that the site of the solution of an anaesthetic is a hydrophobic part of the glycine receptor protein. Support for this notion comes from the fact that the pharmacology of pressure, as elucidated from pressure-induced convulsions in mammals, closely parallels that of strychnine which is believed to act on postsynaptic inhibition mediated by glycine. □

Mass extinctions and missing matter

SIR — The approximate 30-Myr periodicity that appears to exist in the record of mass biological extinctions and terrestrial impact cratering has been interpreted by Rampino and myself[1] as evidence of a quasi-periodic bombardment of the Earth by comets that have been perturbed into Earth-crossing orbits by close gravitational encounters of the Solar System with massive interstellar clouds of gas and dust. In this model, the underlying clockwork is the Solar System's vertical oscillation through the midplane of the Galaxy, towards which most of the massive interstellar clouds are concentrated.

The downward force exerted by the Galaxy will also perturb the Solar System's comet halo, but will not produce any periodicity. To see why, first observe that the Solar System's vertical orbit[2] lies wholly within the linear domain of the galactic force law[3,4], so that the vertical galactic acceleration is simply $K(z) = -4\pi G\varrho_0 z$, where ϱ_0 represents the local mass density of material near the galactic plane. It follows that the difference between the galactic acceleration of the Sun at galactic height z and that of a comet at a distance r from the Sun in the direction of the galactic plane is $K(z) - K(z-r) = -4\pi G\varrho_0 r$. By equating this small galactic tidal acceleration to the local acceleration of the comet towards the Sun, $-GM_\odot/r^2$, a 'tidal radius' for the comet halo is readily obtained: $r_t = (M_\odot/4\pi\varrho_0)^{1/3} = 1.5 \times 10^5$ AU. (For comparison, the Galaxy's central force field and differential rotation impose a tidal limit[5] of 3×10^5 AU.) Because of its independence of galactic height, r_t differs from the tidal radius that is derived for an inverse-square galactic force law, valid very far from the galactic plane[6]. Thus, the comet halo, unlike a far-ranging globular star cluster[7], never experiences a periodic 'gravitational shock' as it passes up and down through the galactic disk (contrary to ref. 8), although it does suffer a constant amount of compression in the vertical direction. For this reason, individual objects like interstellar gas and dust clouds seem to be needed as perturbers.

Could other dark perturbing objects also be important? The disk of our Galaxy probably contains a large quantity of 'invisible matter'. Kinematical studies have produced a range of estimates for the total mass density ϱ_0 in the solar neighbourhood (believed to be typical of the part of the galactic plane that is accessible to the Solar System) equal to 0.14–0.24 $M_\odot$ pc^{-3} (refs 3, 4, 9–12). Direct counts of observed stars, gas, and dust have turned up only 0.10–0.11 $M_\odot$ pc^{-3} (refs 4, 10), and so the missing disk material could amount to as much as ~ 0.14 $M_\odot$ pc^{-3}.

The effectiveness of any seen or unseen matter in perturbing the Solar System's comet halo depends only on the local mass density of this matter, ϱ_0. From equations (11) and (12) of Hills[13], the mean time interval between random encounters of the Solar System with objects of mass density ϱ is given by $\tau_s = \varrho^{-1} a^{-2}_{\min}$ Myr, if ϱ is in units of $M_\odot$ pc^{-3} and $a_{\min}$ in units of 2×10^4 AU, where $a_{\min}$ is the minimum semimajor axis of those comets for which the loss cone is filled by an encounter. (This result depends on the impulse approximation and point-mass approximation, which turn out to be adequate assumptions for all cases considered here.) Hills' equations (13) and (19) (ref.13) (with $n = 2$) provide the total number of comet collisions with the Earth during an encounter, $N = N_0 a^{-2}_{\min}$, where $N_0 = 4$ or $N_0 = 0.2$ depending on whether Everhart's[14] or Weissman's[15] rate of present-day comet impacts is assumed. In either case, the shower of comets[13] lasts $\tau_1 = 11 a^{3/2}_{\min}$ Myr. Because the outer radius of the main comet reservoir probably lies at ~ 2×10^4 AU (refs 13, 16–19), $a_{\min}$ is not likely to exceed 1.

For the Solar System's vertical motion within the Galaxy to significantly modulate the background comet flux arising from random showers, the most important perturbing objects must not only have a high mass density but must also be concentrated fairly strongly towards the galactic plane. The total comet flux into the inner Solar System is due to solar encounters with known stars (~ 0.05 $M_\odot$ pc^{-3}) (ref.4), known interstellar gas and dust clouds (~ 0.05 $M_\odot$ pc^{-3}(ref.20), interstellar comets (< 6×10^{-4} $M_\odot$ pc^{-3} (ref.21), and invisible matter (≤ 0.14 $M_\odot$ pc^{-3}). If the invisible matter consists of small (or cold) interstellar molecular clouds, which would probably be concentrated strongly toward the galactic plane like the known molecular clouds and the youngest stars (~ 0.04 $M_\odot$ pc^{-3}) (refs 4,20), then the total percentage of local material lying in the flat subsystem could be as high as 75%. Even without invisible matter, the total percentage would still be fairly high, 40%. In all cases, the encounter time τ_s would be acceptably shorter than the Solar System's galactovertical half-period, $P_{1/2} = (\pi/4G\varrho_0)^{1/2} \approx 30$ Myr, and so galactic modulation could arise.

If, however, the invisible material consists of a large population of old, dead stars, with a relatively small galactic concentration, the percentage of local matter belonging to the flat subsystem could be as low as 17%. This would be insufficient to modulate the background comet flux into the inner Solar System. It might be argued that most of these dead stars are young objects, not yet kinematically dispersed far from the galactic plane. However, they would also have to be old enough to have migrated into the area between the star-forming spiral arms (so as to adequately cover the region of the galactic plane that the Solar System traverses in its revolution around the galactic centre). Their ages would consequently[22] need to lie in the narrow range 10^8–10^9 yr. Yet it is very unlikely that much of the invisible matter consists of dead stars; the space densities of faint white dwarfs[23] and of black dwarfs[24–26] are observed to fall off rapidly with declining luminosity (at least to $M_V = 21$), while most neutron stars and stellar black holes are expected to be derivatives of massive main-sequence stars, whose space densities, at least today, are observed to be extremely low[4].

If future observations reveal a large secondary maximum in the luminosity functioin of dead stars at a lower light level (perhaps because star formation has been very sporadic), the implications for the present hypothesis of Galaxy-modulated comet impacts on Earth[1] could be profound.

The case against impact extinctions

SIR — Some people think that the impact hypothesis for the mass extinction at the Cretaceous–Paleogene boundary is 'proved'[1,2]. So it is, if one considers selectively one set of evidence. However, it is equally convincingly disproved if one considers selectively another set of evidence. I have recently reviewed this topic[3], evaluating the literature through 1983; no valid later work known to me materially affects any of the many arugements in each direction given in that paper and only one adds a useful new argument. The best evidence in each direction does not impinge on that for the other, and neither side has a satisfactory explanation for the opposing evidence.

The arguments against the effect of an impact, all discussed in my review, are:

(1) A *Protunqulatum* community lacking dinosaurs.
(2) Appearance and progressive evolution of the *Protunqulatum* community just before the boundary.
(3) Freshwater community unaffected.
(4) Last occurrence of dinosaurs being detectably below boundary in Montana and vicinity
(5) Existence of transitional floras below boundary.
(6) Putatively extraterrestrial material below boundary.
(7) Absence of effects of elimination of stratospheric ozone.
(8) Coincidence with culmination of very large regression.
(9) Marsupials but not placentals nearly eliminated; most arboreal multituberculates and birds survived.
(10) Darkness expected to occur too often.
(11) Concentration of Ir, etc., in reduced material, with associated timing anomaly.
(12) Dinosaurs occurring well above the palynological boundary in New Mexico.
(13) Effect of predicted cooling not seen.
(14) Effects of predicted acid rain not seen.
(15) Absence of turbidites at boundary (if marine impact) and apparent absence of large terrestrial crater.

The first two items refer to a community of Paleocene aspect, whose members were ancestral to much of the Paleocene fauna and which appeared in Montana 4 × 10^5 yr before the boundary. Smit and van der Kaars[5] claim that the sediments involved postdate the boundary, but their work ignores the field relationships given in a detailed geological map[6] (other evidence and will be refuted more adequately in a paper in preparation by several people). That my list of evidence is one-sided, reflects merely the greater publicity which given to evidence favouring an impact as the cause of the extinction.

The results of Bohor *et al.*[4], who found quartz fragments at the boundary which had been shocked at very high pressure, are at first sight strongly favourable to an impact. But until possible alternatives such as a uniquely powerful explosion (perhaps analogous to the smaller ones of kimberlites) are considered, some scepticism seems appropriate. Unless there were mutliple impacts[2], for which there is no evidence (despite considerable search) except an unconvincing [3] interpretation of osmium isotope ratios[7], it is not apparent how the impact hypothesis can be modified to resolve the major conflicting evidence. Yet volcanism, even broadly conceived, has equally severe problems[3,4]. Coincidence is not a satisfactory basis for theory.

On the "late Eocene mass extinction", I know of no evidence that it exists. For instance, there are as many last appearances of marine families recorded in the middle Eocene as in the late Eocene[8], neither value being unusually large; species extinctions are not concentrated at one horizon[9]; and the mammalian turnover is later[9] and clearly involves at least a major biogeographic interchange[10].

Did komatiitic lavas erode channels on Mars?

SIR — Huppert *et al.*[1] show that terrestrial Precambrian komatiitic lavas may have erupted as very hot, highly fluid, turbulent flows capable of eroding deep channels and melting and assimilating rocks over which they flowed. We have argued[2] that the chemical composition of martian fines, measured by Viking Lander spacecraft[3], indicate derivation from mafic igneous rock, that terrestrial Precambrian komatiitic lava would be a good candidate for an analogue. Using our derived Mars composition, Schonfeld[4] calculated that martian lavas had viscosities of about 0.5 Pa s. The new findings of Huppert *et al.*, that komatiitic lavas could have been as hot as 1,700° C and as low in viscosity as 0.1 Pa s, renew our interest in the possibility of martian channel formation by lava[5].

Various channels on Mars have been ascribed to tectonism, earthflows, wind action, glacial ice, and flowing basaltic lava, but the majority have features (braided channels, terraced walls, sculpted islands, dendritic tributaries, meanders, increase in size downstream) that have forced most observers to conclude they were formed by running water. However, the source of the water, and where the water is today, remain vexing problems. (Most workers believe that water had to be more abundant on Precambrian Mars and what water remains is locked principally in ground ice). Most of the previous objections to lava as the principal erosive agent on Mars (see ref.6) are based on observed characteristics of basalt. Such lavas erupt at around 1,200° C and have viscosities more than fifty times that found by Huppert *et al.* for komatiites. If martian lavas were komatiitic, however, a water-like fluid would have been available and such a fluid would explain not only channel formation, but also the enormous lateral extent of martian flows and the absence of apparent outflow deposits (sediments) in the basins into which the large channels discharge. Finally, if water did not carve martian channels, the complex schemes to explain the present lack of surface water, including gross changes in the atmosphere/climate of the planet, are not needed.

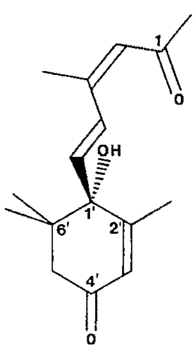
A question of chirality

SIR — Hanke writes (*Nature* **310** 272; 1984) "It is quite remarkable that immunoglobulins should be able to discriminate between the enantiomers because, as can be seen from the diagram, the molecule of abscisic acid is almost symmetrical...".



To my eye, the degree of chirality shown by abscisic acid is almost exactly the same as that between my feet. Perhaps Hanke is more supple than me, but I cannot put my right foot into a left shoe. Why should a globulin be more flexible?

Origins of biomolecular handedness

Stephen F. Mason

Chemistry Department, King's College, London WC2R 2LS, UK

Classical mechanisms proposed for the transition from racemic geochemistry to homochiral biochemistry in terrestrial evolution generally ascribe to chance the particular handed choice of the L-amino acids and the D-sugars by self-replicating systems. The parity-violating weak neutral current interaction gives rise to an energy difference between a chiral molecule and its mirror-image isomer, resulting in a small stabilization of the L-amino acids and the L-peptides in the α-helix and the β-sheet conformation relative to the corresponding enantiomer. The energy difference suffices to break the chiral symmetry of autocatalytic racemic reaction sequences in an open non-equilibrium system.

THE class of handed or enantiomorphous molecules (see Fig. 1) was first identified in 1848 by Pasteur[1] from his study of optical activity, the rotation of the plane of polarized light by natural products in the fluid state or in solution. As a student, Pasteur found that the crystals of the sodium ammonium salt of an optically inactive tartaric acid, then termed racemic acid, are separable into two morphological classes, distinguished by hemihedral crystal facets which, in the one set, have a non-superposable mirror image relation to the corresponding facets of the other set of crystals. One set proved to be isomorphous with the sodium ammonium salt of the major naturally occurring isomer, (+)tartaric acid, and gave the same positive specific optical rotation in aqueous solution. The other set, morphologically enantiomorphous, gave a specific rotation of the same magnitude but negative in sign, and liberated the optical isomer, (−)tartaric acid, on acid treatment.

From the view then generally prevailing (see ref. 2), that a crystal and its constituent molecules are morphologically 'images of each other', Pasteur[1] concluded that the individual (+) and (−)tartaric acid molecules are structurally dissymmetric, related as non-superposable mirror-image forms, like the macroscopic hemihedral crystals of the corresponding sodium ammonium salts. While still current in France,[3] Pasteur's term *dissymétrie* became generally supplanted elsewhere by Kelvin's expression 'chirality'[4] from the familiar analogy of the morphological mirror-image relation between the left and the right hand.

Pasteur soon came to the view that chiral molecules, characterized by their fluid-state optical activity, and hemihedral crystals are the product of universal dissymmetric influences, exemplified by the polar fields of electricity and magnetism, or composite rotations, such as those of the inherently-chiral solar system[5]. Following the discovery by Faraday[6] of magnetically-induced optical activity in isotropic transparent media, Pasteur grew normally holohedral crystals in a magnetic field with the object of inducing hemihedral crystal forms. Not discouraged by the negative results, Pasteur attempted to induce optical activity in synthetic products by running reactions in a centrifuge, and to modify the optical activity of natural products by rotating the plants producing them with a clockwork mechanism. These experiments, and their negative results, were reported by Pasteur[5,7] in his later years (1884), in the course of a restatement of his views on the universality of dissymmetric forces and structures in nature. Previously, in his lectures on molecular dissymmetry, Pasteur[8] (1860) had proposed that optical activity provides a demarcation criterion between the products of laboratory synthesis and the natural products synthesized biochemically by living organisms.

Chiral synthesis

Le Bel[9] (1874), in his pioneer work parallel to that of van't Hoff[10] on the connection between optical activity in the fluid phase and enantiomorphous three-dimensional molecular structures, proposed forces of dissymmetry additional to those considered by Pasteur. The reactions of symmetrical substrates, whether achiral or a racemic mixture of enantiomers, carried out photochemically with left- or right-circularly polarized electromagnetic radiation, or thermally with a chiral catalyst, would be expected to produce an excess of a particular enantiomeric product[9].

The differential absorption of left- and right-circularly polarized light by chiral molecules in solution, isotropic circular dichroism, was discovered by Cotton[11] (1895). It provided a physical basis for the proposed chiral photodiscrimination, which however eluded Cotton[12] himself. The first unambiguous photoresolutions of fluid racemic mixtures were achieved by Kuhn and co-workers[13,14] (1929), and the first chiral photosyntheses from achiral precursors, notably, the helicene enantiomers[15–17], are relatively recent.

The second of the dissymmetric influences on reactivity considered by Le Bel[9], the use of chiral reagents in thermal reactions, was implicit in Pasteur's[18] (1853) discovery of diastereomers. The introduction of a second chiral centre into an enantiomer gives two diastereomers with different chemical and physical properties, apart from optical activity. In general, the yields of the two diastereomers are unequal, as Fischer[19] (1894) showed in the step-wise synthesis of the D-series of sugars from (+)glyceraldehyde, and the L-series from the corresponding (−)enantiomer. Fischer[19] found the reactions of diastereomers mediated by naturally-occurring chiral catalysts to be particularly selective, showing that α-methyl-D-glucoside is hydrolysed by maltase, but not by emulsin, whereas β-methyl-D-glucoside is cleaved by emulsin, but not by maltase, although neither of the corresponding L-glucosides are affected by either enzyme preparation.

The stereochemical 'key and lock' hypothesis of Fischer[19,20], based upon these and analogous observations, went far to account for the substantial homochiral biochemistry of living organisms, the general adoption of only one of the two enantiomeric series of the α-amino acids and, equally, of the sugars. Subsequent developments of the 'key and lock' hypothesis suggest a more dynamic relation, a mutual stereochemical adaptation between the catalyst and the substrate. Pauling[21] proposed that the catalytic activity of an enzyme derives from the steric distortion of the substrate when it binds, towards the structure

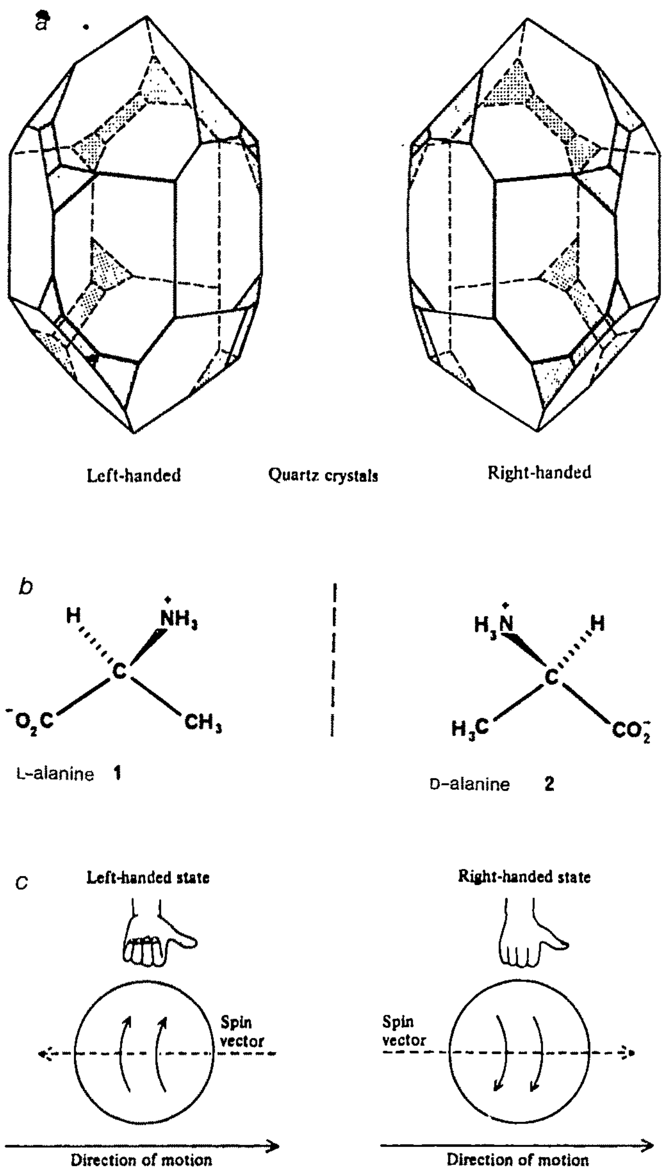

Fig. 1 A chiral or handed structure is not superposable upon the corresponding mirror-image form, its enantiomer. Chirality appears macroscopically (*a*), as in quartz crystals, in which the minor crystal facets follow either a left-handed or a right-handed sequence when viewed in a direction along the three-fold crystal axis. At the molecular level, chirality is exhibited by organic compounds (*b*), such as L-alanine (1) and D-alanine (2), in the respective left-handed (anticlockwise) or right-handed (clockwise) sequence of the NH$_3^+$, CO$_2^-$, and CH$_3$ groups attached to the central carbon atom, when viewed with the bonded hydrogen atom remote from the observer. In the case of a particle (*c*), such as an electron, the left-handed or right-handed chirality derives from the respective antiparallel, or parallel, relation between the linear momentum vector and the angular momentum axial vector.

of the transition state for reaction, a view supported by X-ray structural studies of crystalline enzyme-substrate complexes and by a range of related fluid-state investigations[22].

The results of kinetic studies and product analyses of the synthesis and hydrolysis of polypeptides provide further grounds for the adoption of a homochiral biochemistry by living systems. The polymerisation of a given enantiomer of an α-amino acid, in the form of the *N*-carboxyanhydride derivative, proceeds at a rate faster by a factor of ~20 than that of the corresponding racemic mixture in the same conditions[23]. The partial polymerization of near-racemic mixtures of D- and L-leucine-*N*-carboxyanhydride, containing a small excess of one of the enantiomers, gives a polyleucine in which the original enantiomeric excess is enhanced and, when the polymer product is partially hydrolysed, the degree of homochirality in the residual polymer is further increased[24].

Although the general stereochemical and energetic bases, if not the detailed mechanisms, are clear for the natural selection of an efficient homochiral biochemistry by living organisms, the particular choice of the L-amino acids and the D-sugars appears generally to be a matter of chance[25]. The classical dissymmetric influences, based on electromagnetism or gravitation and the Coriolis force of rotation, might have equally generated an initial enantiomeric excess of D-amino acids or L-sugars which propagated to an enantiomeric homochiral biochemistry.

Chiral fields

In an application of his general principle, that the symmetry of a physical effect implies a corresponding symmetry in the causes, Curie[26] pointed out that each of the polar fields which Pasteur had taken to be dissymmetric has mirror symmetry individually. Any type of chiral field is necessarily composite, with collinear axial and polar vector components, or corresponding higher-rank tensor components. The simultaneous application of a magnetic field and a parallel or an antiparallel electric field provides such a chiral combination, the parallel relation being transformed into the enantiomeric antiparallel relation by mirror-reflection or, equivalently, by space inversion.

Curie[26] conjectured that the synthesis of an optically-active substance from an achiral substrate might be feasible by running the reaction in a chiral combination of an electric and a magnetic field. The conjecture was refuted, at least for the case of uniform static fields, by applications[27–29] of Wigner's general principle[30], that a complete experiment subject to space-inversion and time-reversal should give a transformed experiment which is possible in principle. The application of the parity operator, space-inversion, to a chiral molecule in parallel, static, and uniform electric and magnetic fields transforms the molecule into its mirror-image isomer and the fields into the enantiomeric antiparallel combination. The reversal of the direction of the circular electric current producing the magnetic field, equivalent to time-reversal, leaves the mirror-image isomer unchanged but restores the parallel relation of the electric and the magnetic field. The cycle implies that the fields do not discriminate between a chiral molecule and its enantiomer, both substances having an identical energy in the same combination of environmental fields, so that a racemic mixture inevitably results from a reaction carried to equilibrium in the field combination.

Similar conclusions are derived for the chiral products of reactions run in a centrifuge rotating clockwise or anticlockwise horizontally in a vertical gravitational field[28,29]. The simultaneous application of three uniform fields, electric, magnetic, and gravitation, for example, is required to discriminate between the enantiomeric products from achiral reactants. The discrimination with realistically attainable fields is, however, vanishingly small[28,29]. The most significant of the classical chiral fields is that of circularly polarized electromagnetic radiation, but the discrimination is even-handed, and the pure electromagnetic circular dichroism of a D-isomer, while opposite in sign, is of equal magnitude to that of its L-enantiomer.

Parity non-conservation

A group of anomalies in elementary particle physics led Lee and Yang[31] to conclude that parity, space-inversion equivalence, is not conserved in the weak nuclear interaction, contrary to the original principle of Wigner[30]. A consequence of parity violation, the asymmetric β-decay of radionucleides, was observed in the decay of cobalt-60 to nickel-60 with the emission of an electron[32], and in the emission of the corresponding antiparticle, the positron[33], in the decay of cobalt-58 to iron-58. These and other studies of the weak interaction establish an intrinsic left-chirality for the electron, antiparallel momentum and spin vectors, and right-chirality for the positron, parallel momentum and spin vectors, in proportion to the ratio of the velocity of the particle, or the antiparticle, to the velocity of light.

The discovery of parity non-conservation in the weak interaction led to the chemical expectation that the β-decay of nucleides should give rise to an enantio-differentiating radiolysis of racemic mixtures, or to the corresponding photolysis by the circularly-polarized electromagnetic radiation arising from the progressive retardation of the emitted spin-polarized electron or positron[34]. As yet, no unequivocal enantio-selective radiolyses of racemic mixtures have been reported by the agency of β-radionucleides[35], or of spin-polarized electrons[36] or spin-polarized positrons[37] produced by particle accelerators.

The weak interactions initially investigated, notably β-decay, are mediated by the charged massive bosons, $W^{\pm}$, in the weak charged currents, which have only a minor, high-order, significance for charge-retaining atomic and molecular properties. An additional weak neutral current interaction, involving the massive neutral boson, Z^0, recently detected, together with its charged counterparts, $W^{\pm}$, at CERN[38], emerged from the unification of the weak with the electromagnetic interaction by Weinberg[39] and Salam[40]. The weak neutral current (WNC) is more significant for charge-retaining properties of atoms and molecules, including the stationary state properties, as the perturbation of the state properties by the parity-violating electro-weak interaction between each valence or inner-shell electron and the nucleus or other electrons of an atom remains finite in the non-relativistic limit.

Due to the WNC interaction, all atoms and achiral molecules, as well as enantiomers, are expected to be optically active to electromagnetic radiation and to polarized matter waves. Further, enantiomeric molecules have different electronic binding energies, owing to the dependence of the WNC interaction between different atomic centres on the particular handedness of the molecular stereochemistry. Just as the electron and the positron have intrinsic enantiomeric chirality, so a D-isomer composed of electrons and other particles has a true isoenergetic mirror-image L-enantiomer made up of positrons and other antiparticles in a hypothetical counter-world of antimatter, but the natural particulate L-isomer is not energetically equivalent[41].

The optical rotation of electromagnetic radiation by a free atom, due to the WNC interaction, is expected to be proportional to Z^6, where Z is the atomic number[42,43]. Accordingly, vapours of heavy metal atoms have been investigated, and an optical rotatory dispersion of the correct sign and order of magnitude has been reported for electronic transitions of atomic bismuth, lead, thallium and caesium in the vapour phase[42–44]. Similarly, the matter wave analogue of optical rotation, due to the WNC interaction, has been observed in the rotation of the spin-polarization of a cold neutron beam by crystals of metallic tin, the tin-117 isotope giving a particularly large rotation[45].

The WNC interaction in chiral molecules gives rise to a parity-violating energy shift, E_{pv}, which is positive for one isomer and negative for its enantiomer. Early estimates[46,47] gave a magnitude order, $E_{pv} \sim 10^{-12}$ eV, based upon a crystal field model where a single heavy atom is perturbed by a chiral electrostatic field. More fundamental estimates of E_{pv}, based upon the molecular orbital wavefunctions, are substantially smaller for chiral molecules composed of light atoms[48]. The wave functions of a model chiral ethylene molecule, twisted through 10° to dihedral symmetry[49], provide an energy shift, E_{pv}, of $\sim \pm 5 \times 10^{-19}$ eV, positive for the (R)-isomer and negative for the (S)-enantiomer[48].

Ab initio calculations on a simple chiral molecule, hydrogen peroxide[50], show that the energy shift, E_{pv}, is sensitive to the molecular conformation, with an optimum value of the same magnitude, $\sim \pm 5 \times 10^{-19}$ eV. The energy shift, E_{pv}, for the α-amino acids is also sensitive to the molecular conformation and, at the conformation preferred in aqueous solution, L-alanine is more stable than the D-enantiomer by $\sim -6 \times 10^{-19}$ eV. The extension of the calculations to a peptide unit of a polypeptide in the α-helix or the β-sheet conformation shows that the polypeptides from the L-amino acids are stabilized relative to the corresponding D-enantiomers in both conformations by $\sim -9 \times 10^{-20}$ eV for each peptide unit[51,52].

These parity-violating energy differences between enantiomers amount to no more than $\sim -2 \times 10^{-14}$ J mol^{-1} per amino acid residue in the polymer, corresponding to an enantiomeric excess of some 10^6 L-peptide molecules per mole of racemate in thermodynamic equilibrium at ambient temperature. Although small, the enantiomeric excess indicates a determinate intrinsic bias in organic nature for the particular handedness which evolved historically into homochiral dominance. The sign and the magnitude of the parity-violating energy shift for a sugar enantiomer remains undetermined as yet. Chemically, however, the D-sugars are connected with the L-amino acids through the conversion of D-glucosamine to L-alanine[53].

Chiral symmetry breaking

Observable consequences of the parity-violating energy difference between enantiomeric molecules, owing to the small magnitudes involved, require either an extended, cumulative, amplification mechanism, or an open, dynamic, metastable system with a selection between alternative outputs triggered by a very small perturbation. Systems of the latter type involve the catastrophe theory of symmetry-breaking, in which ordered dissymmetry emerges from an open non-equilibrium process[54]. Kinetic reaction sequences designed to produce a spontaneous transition from a racemic reaction process to the one or the other of the two constituent homochiral reaction sequences postulate autocatalytic branched-chain kinetics in each reaction channel, accompanied by competitive cross-reactions between the two enantiomeric sequences that are mutually inhibitory and form inactive products[55–61]. An open reaction scheme proposed recently has the general form[59],

$$\mathrm{A}+\mathrm{B} \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} \mathrm{L} \qquad (1a)$$

$$\mathrm{A}+\mathrm{B} \underset{k_{-1}}{\overset{k'_1}{\rightleftharpoons}} \mathrm{D} \qquad (1b)$$

$$\mathrm{L}+\mathrm{A}+\mathrm{B} \underset{k_{-2}}{\overset{k_2}{\rightleftharpoons}} 2\mathrm{L} \qquad (2a)$$

$$\mathrm{D}+A+B \underset{k_{-2}}{\overset{k'_2}{\rightleftharpoons}} 2\mathrm{D} \qquad (2b)$$

and,

$$\mathrm{L}+\mathrm{D} \xrightarrow{k_3} \mathrm{P} \qquad (3)$$

In an open non-equilibrium system with an input of achiral substrates A and B, and an output composed of the enantiomers L and D, together with the inactive product P, formed irreversibly, the overall process remains racemic if corresponding primed and unprimed rate constants are equal and the input remains small. As the input concentrations of A and B are increased, the racemic process becomes metastable and switches spontaneously into the one or the other enantiomeric homochiral reaction sequence, ($1a$) and ($2a$) or ($1b$) and ($2b$), breaking the racemic chiral symmetry[59]. In a collection of such systems, it is expected that the L-channel would be adopted by one half of the reaction sequences and the D-channel by the other half.

At the onset of racemic metastability in the reaction sequence (1), (2) and (3), the bifurcation point dependent on the substrate input, the system becomes hypersensitive to small chiral perturbations, which determine the particular homochiral channel adopted by the system. The chiral perturbation may be external to the system, or intrinsic, such as a small difference, ΔE, between the activation energy of corresponding primed and unprimed reactions in the processes (1) and (2). Thermal fluctuations, which increase with a rise in temperature, offset the hypersensitivity of the reaction sequence at the bifurcation to chiral perturbations, and the overall chiral discrimination governing the choice of a homochiral channel becomes proportional to $(\Delta E/kT)$. The critical magnitude order, $(\Delta E/kT) \geq 10^{-17}$, is

21-1-87 A. Laite 4630

R 429

found[59] to govern the selection of a particular enantiomeric reaction sequence in the series (1), (2) and (3).

At ambient temperature, the estimated parity-violating energy differences between enantiomers composed of light atoms correspond to the lower limit of the criterion, $(E_{pv}/kT) \sim 10^{-17}$. The determinate selection of the lower-energy homochiral reaction sequence is promoted by a slow passage through the transitional point where the racemic reaction process bifurcates into the two homochiral reaction channels, that is, by small increments of the input concentrations of the substrates A and B, extended over long time periods. From the parity-violating energy differences between the enantiomers of the α-amino acids and of the polypeptides, it is estimated that the selection of the lower-energy L-series occupied a minimum time of $\sim 10^3$ years[61].

An external chiral perturbation, ΔE_{ext}, of the reaction sequence (1), (2) and (3), made up from the combination of three macroscopic vector fields, electric, magnetic, and gravitation, does not meet the above mentioned criterion because, even with extreme field strengths, the ambient temperature ratio amounts to no more[59] than $(\Delta E_{ext}/kT) \sim 10^{-19}$. The external perturbation of circularly polarized light is not eliminated however. While the pure electromagnetic circular dichroism of two enantiomers is equal in magnitude and opposite in sign, the electro-weak interaction gives each atom in the two molecules a small additional optical activity which is of the same sign for each enantiomer. The magnitude-symmetry of the differential absorption of left and right circularly polarized light by enantiomeric molecules is broken by the WNC interaction, and even equally alternating opposite circular components in the solar radiation would tend to favour one of the two enantiomeric reaction channels in the long run. Owing to multiple aerosol scattering, twilight is ~0.1% circularly polarized, particularly in the near infrared region, with one circular component in excess at sunrise and the other at sunset[62].

A uniformitarian model, alternative to that of the catastrophic bifurcation of competitive reaction sequences, depends upon the progressive accumulation of small differences between each successive enantiomeric stage in a manifold chemical or physical process, starting from an achiral or racemic substrate and terminating with an enantiomerically enriched or homochiral product[63–69]. The accumulation model, proposed initially to account for the prevalence of homochiral biopolymers among the natural products[63], postulates that a small difference between the activation parameters of the enantiomeric monomers, ΔE, effective in relation to the thermal fluctuations, kT, through the ratio, $\varepsilon = (\Delta E/kT)$, at each of the n stages of the polymerization, results in an excess of one of the homochiral n-fold polymers. The relative enantiomeric excess of the favoured n-fold polymer, $\mathrm{L}(n)$, say, is dependent upon the degree of polymerization, n, and the advantage ratio, ε,

$$[\mathrm{L}(n) - \mathrm{D}(n)]/[\mathrm{L}(n) + \mathrm{D}(n)] \simeq n\varepsilon \qquad (4)$$

Subsequent applications of the accumulation model include cases of the spontaneous optical resolution of racemic substances by crystallization[66–69]. By the use of the relation (4), the advantage ratio is estimated at $\varepsilon \sim 10^{-10}$ from the distribution of (+) and (−) crystals formed in 63 recrystallizations of racemic sodium ammonium tartrate[69], compared to a value, $\varepsilon \sim 10^{-6}$, obtained from the polymerization of monomeric alanine derivatives[64]. Both values are substantially larger than the minimum ratio, $\varepsilon \sim 10^{-17}$, required by the bifurcation model[59], and approximately equal to the ambient temperature ratio, E_{pv}/kT, for the parity-violating energy difference between enantiomers composed of the lighter elements[50–52].

The condensation of optically-impure monomeric α-amino acid derivatives gives heterochiral polymers[23,24], not the homochiral polymers as required by the progressive accumulation model[63]. Further, no equilibrated racemate is expected to be truly equimolecular in its constituent enantiomers, owing to the parity-violating energy difference between them, so that neither the polymerization of enantiomeric monomers, nor an optical resolution by crystallization, begin with exactly equal enantiomer concentrations. Synthetic racemic camphor is reported to contain an excess of up to 3 or 4% of (+)camphor[68], and, after four successive recrystallizations of racemic tartaric acid, a minor excess of the (+)isomer was found to remain in the final crop of crystals and in the last of the mother liquors[70].

In a general criticism of the progressive accumulation model, it is argued that the condensation of an exactly equimolecular mixture of enantiomeric monomers would necessarily terminate with an equimolecular mixture of homochiral n-fold polymers, the enantiomeric enrichment of the incomplete process being transient[58]. The objection is applicable to a closed system of optically-stable enantiomers in a racemic process, but not to an open system, with a continuous input of substrate and output of chiral product, nor to a closed system in which a stable chiral product forms from an achiral or optically-labile substrate.

Sometimes, the formation of enantiomorphous crystals by an achiral substance, for example sodium chlorate[71], or an optically-labile racemate, for example allylethylmethyl-anilinium iodide[72], gives, in a single experiment, crystals predominantly of one hand. As a result of many experiments, involving 46 crystallizations and 3,206 crystals in the case of sodium chlorate[71], the weighted mean of the number of (+) and (−) crystals approaches equality. However because the departure from equality attains the 90% confidence level, it is not a matter of chance in the case of the terrestrial distribution of quartz where, over a total collection of 16,807 crystals, a 1% enantiomeric excess of (−)quartz is documented[73]. The (−)quartz bias is common to all the locations sampled in the Americas, Europe, and Asia, and the collection excludes 931 unrepresentative sets of crystals, in which the mean enantiomeric excess of (−)quartz rises to 9.8%.

The excess of (−)crystals in the quartz laid down in the post-biotic period may arise from chiral biomolecular influences, although the elevated temperatures favouring the hydrothermal crystallization of quartz do not support this. While L-analine is preferentially absorbed from the corresponding racemic mixture by (−)quartz[74,75], this and other α-amino acids are racemised at 142 °C in aqueous solution with a halflife of no more than a few days[76]. If a significant proportion of crystalline quartz was laid down in the prebiotic era, the excess of (−)quartz provides not only a possible perturbation of determinate chirality in the bifurcation or the accumulation model for the generation of biomolecular homochirality, but also evidence for a small intrinsic parity non-conservation in the physical world at large.

Conclusion

The significance of the electro-weak interaction is established in particle physics, through the detection of the massive neutral boson, Z^0, mediating the weak neutral current[38], and in atomic physics, by measurements of the optical activity of heavy metal atoms[42–44]. The importance of the WNC interaction for chiral systems, particularly biomolecules, is confined as yet to small enantiomers, composed of the lighter elements, for which reliable *ab initio* computations are currently feasible. The calculations to date of the parity violating energy difference between the enantiomers of the α-amino acids and the polypeptides in the α-helix and the β-sheet conformation provide a basis for the viewpoint that the adoption of the L-α-amino acid series, at least, in the homochiral biochemistry of living organisms was fully determinate, and not merely a matter of chance.

The current calculations refer to the range of molecular conformations stereochemically permitted for a small enantiomer in its electronic ground state. Corresponding computations of the potential energy surfaces for the stereoisomeric transition states connecting an archiral set of substrates with an enantiomeric pair of products are required, for example the reaction surfaces linking an aldehyde and ammonia or hydrogen cyanide with the enantiomeric aldehyde-ammonia or cyanohydrin products. These component reactions make up the traditional

Strecker synthesis of α-amino acids from carbonyl compounds, a synthesis which is considered to be significant in biogeochemical evolution. The evaluation of the potential energy surfaces for enantiomeric reactions, including the parity-violating energy shift, has importance for both the bifurcation and the accumulation mechanism proposed for the emergence of biochemical homochirality.

As yet, an open, flow-reactor, reaction sequence, involving the autocatalytic chain-branching of enantiomeric intermediates, has not been devised for an experimental investigation of the triggered bifurcation model for the spontaneous development of homochiral from racemic reaction systems. The nearest analogous reaction sequences characterized, although rather remote, involve the autocatalytic chain-branching of atomic radicals and other achiral intermediates, notably, the oscillatory chemical reactions of the Belousov-Zhabotinsky type, in which the reaction system switches spontaneously from one quasi steady state to another[54,77–79].

The alternative accumulation model for the emergence of homochirality from racemic systems is the more readily testable in principle at present. The practical limitation of the investigation of racemic monomer condensations, namely, the formation of heterochiral polymers, has an analogue, the formation of heterochirally twinned crystals, in studies of the spontaneous optical resolution of racemates by crystallization. The heterochiral Brazil twinning of quartz crystals provides an example, although the twinning is readily identified and the homochiral crystals are the more generally prevalent[73].

A study of the relative abundance of the (+) and the (−) crystals formed by solutions of an optically-labile racemate, or an achiral substance, affords an immediately practicable method of investigating the parity-violating energy difference between enantiomers, due to the electroweak interaction. Although the energy difference is small, it is multiplied by the number of molecules, or the number of unit cells, in a macroscopic crystal, as prescribed by relation (4). Further, the parity violating energy difference between enantiomers is expected to be proportional to Z^5, where Z is the atomic number of the heavy atom or atoms in the molecule[47,48], and there are indications, from the *ab initio* calculations of the energy differences carried out to date, that such a proportionality holds to a fair approximation[52].

Reports in the literature describe the formation of predominantly dextro-rotatory crystals from aqueous solutions of potassium dodecatungstosilicate[80–82], and of the corresponding dodecamolybdosilicate with a smaller, but still substantial, enantiomeric excess[82]. A similar substantial excess of dextro-rotatory crystals is reported for 21 recrystallizations of allylethylmethylanilinium iodide[72]. These salts contain relatively heavy elements, Mo ($Z = 42$), I ($Z = 53$), and W ($Z = 74$). The heaviest element readily available, uranium ($Z = 92$), provides, in the form of sodium uranyl acetate, which crystallizes[83] in the chiral cubic space group, $P2_13$, a promising material for an investigation of the parity-violating energy difference between enantiomorphous structures due to the electro-weak interaction from the relative and absolute abundance of (+) and (−) crystals formed in a spontaneous optical resolution by crystallization.

$H_2{}^{18}O$ and HDO are important climatic tracers largely used to reconstruct continental palaeoclimates. The only thorough way to compare isotopic distributions in precipitation for modern and palaeoconditions is to simulate isotope cycles using atmospheric general circulation models. $H_2{}^{18}O$ and HDO cycles incorporated into our atmospheric general circulation model show good agreement between observed and predicted values for modern conditions.

THE water isotopes $H_2{}^{18}O$ and HDO are important climatic tracers for several reasons. First, on a worldwide scale, ^{18}O and deuterium contents of precipitation decrease with the mean surface-air temperature at the sampling site[1]; this relationship can be used to reconstruct palaeotemperatures, especially at high latitudes where it is particularly well obeyed[2–5]. Second, the relationship between ^{18}O and deuterium contents of precipitation, $\delta D - 8\delta^{18}O = d$ (where d is 10‰ at present[6], with $\delta^{18}O$ and δD expressed in ‰ versus the standard mean ocean water, SMOW, reference), appears to be climate dependent, with smaller values of deuterium excess d during the last ice age (18,000 yr BP)[7,8]; the smaller ice age values found in Antarctic ice cores have been interpreted[7], using a simple model, as reflecting higher relative humidity over the corresponding moisture source regions. Third, spatial and temporal variability of isotope contents of precipitation depends not only on temperature, but also on other atmospheric or geographical parameters[1], such as intensity of precipitation and air mass origin; these further dependencies make climate reconstructions more difficult, but at the same time could be useful as additional climatic information.

Simple models have been derived to study the dependency of isotope contents of vapour and precipitation on atmospheric parameters. These models take into account all the details of fractionation processes but they only deal with prescribed trajectories of isolated air masses. They yield results consistent with the mean temperature–isotope and δD–$\delta^{18}O$ relationships[1,9,10] and can also be used to study more complex dependencies, such as amount of precipitation, air mass origin or meteorological path[11]. The only way, however, to reconstruct the full space–time variations of isotope contents of vapour and precipitation is to include the isotope cycle modelling in atmospheric general circulation models (AGCMs) which explicitly simulate the global and regional features of atmospheric dynamics and thermodynamics, with fully detailed hydrological cycles. Such AGCM modelling of isotope cycles must be tested first on modern conditions for which reasonably good documentation of isotope contents is available: vertical profiles have been measured[12–14], spatial and seasonal distributions in precipitation are reasonably well known, mainly from the IAEA network[15]. Once it has been validated against modern data, AGCM isotope modelling can be used in palaeoclimatic simulations; this may be a first step towards a better interpretation of isotope changes from ancient to present times in terms of changes in atmospheric parameters.

Model description

The AGCM[16] of the Laboratoire de Météorologie Dynamique (LMD) is an 11-layer gridpoint general circulation model with a regular longitude–sine-of-latitude grid, based on primitive equations (horizontal equation of motion, hydrostatic equation, equation of continuity and thermodynamic equation). It includes a fully interactive hydrological cycle as well as prognostic equations for soil moisture, land- and ice-surface temperature and snow depth. Radiative fluxes are calculated taking into account model predicted cloud cover[17]. Orography, land and sea-ice extent, sea-surface temperature and ocean-surface albedo are prescribed external parameters; in the present experiments, land-surface albedo is a prescribed function of soil moisture and snow depth, based on the CLIMAP data set[18].

The basic hydrological cycle of the LMD AGCM[16] includes: surface evaporation over oceans and continents, vertical turbulent diffusion within the planetary boundary layer, horizontal and vertical transport, condensation processes, vertical diffusion in convective clouds and re-evaporation under cloud base. Within this basic hydrological cycle, differentiation between the water isotope species occurs at each phase change through fractionation processes resulting from differences in water vapour pressures and molecular diffusivities. Because HDO and $H_2{}^{18}O$ have lower vapour pressures than $H_2{}^{16}O$, the condensed phase in equilibrium with vapour is enriched in heavy isotopes up to a fractionation coefficient $\alpha (\alpha > 1)$ (refs 19–21). On the other hand, differences in molecular diffusivities[22] lead to kinetic fractionation which changes the relative behaviour of $H_2{}^{18}O$ and HDO for non-equilibrium processes.

Surface evaporation in the basic water cycle is proportional to a drag coefficient C_D, surface wind speed and the difference between the saturated mixing ratio at ground-surface temperature and the air mixing ratio at 10 m above the surface. Over land without snow or ice cover, surface moisture fluxes are limited through an evapo-transpiration coefficient which is a simple increasing function of soil moisture[16]. For $H_2{}^{18}O$ and HDO, the parameterization used for surface evaporation[23] differs over ocean, snow or ice, and land. At the air–ocean interface, water isotope fluxes are treated in the same way as the water vapour flux: that is, they are proportional to the difference between isotopic mixing ratio at ocean surface (in equilibrium with the ocean) and at 10 m. Isotopic drag coefficients are formulated according to Merlivat and Jouzel[9] in order to represent kinetic effects. Over snow and ice, no fractionation is assumed because the time scale of isotope exchanges inside snow or ice crystals is large; therefore, water evaporates with the isotopic ratio of the ground surface. Over land without snow or ice, evaporation is also assumed to occur without fractionation. This assumption, which seemed reasonable from the experimental results of Zimmermann *et al.*[24], has also been used by Rozanski *et al.*[25]; it was recently supported by a simple model and confirmed in studies under controlled environmental and natural conditions[26,27]. Condensation, however, is not treated like evaporation (except over oceans): isotopic equilibrium is always assumed between condensed water and surface vapour.

The basic hydrological cycle uses two ground water reservoirs[16], snow depth and soil moisture, whose evolution is governed by precipitation, surface evaporation or condensation, snowmelt and runoff. Soil moisture is defined as a single-layer parameter without differentiating surface and deep soil contents; runoff occurs whenever soil moisture exceeds a maximum value of 15 cm. Although the isotopic ratio of the soil moisture reservoir is not in reality constant with depth, we use a single ratio for the entire soil water reservoir[23], the evolution of which is governed only by precipitation and condensation, as surface evaporation, snowmelt and runoff have no fractionation effects. This 'mixed single layer' approach is, in fact, the simplest way to retain a memory of the past precipitation–condensation processes without using an expensive multilayer formulation. This simplification is, to some extent, equivalent to a kind of time averaging of precipitations; therefore, it is likely to yield a systematic underestimation of surface variability, and distortions of time lag effects (which may not be too important as long as seasonal variations are not considered). In the case of snow or ice cover, a similar 'mixed single layer' approach is used[23], although the molecular exchanges inside snow or ice are very slow. Furthermore, as there is no fractionation during snowmelt and surface evaporation, we do not distinguish snow and soil liquid water isotope contents. Over land ice, the single mixed-layer reservoir for snow and ice used for isotope budgets has an equivalent water depth of only 1 cm, in order to average precipitations over seasonal time scales. In the case of sea ice, the single reservoir is limited to the snow layer; over bare sea ice, we assume constant isotopic ratios[28]: +3‰ for $H_2{}^{18}O$ and +20‰ for HDO.

Like $H_2{}^{16}O$, the two isotope species HDO and $H_2{}^{18}O$ are diffused vertically across the planetary boundary layer with a turbulent diffusion coefficient depending on static stability and vertical wind shear[16].

Transport is a critical process in isotope modelling[23]. Ordinary second-order finite difference schemes applied to the transport equation are not effective for treating positive quantities which may have large variations from one gridpoint to the next; in particular, they can produce unrealistic negative values. The problem is not very serious when only water vapour is advected, as negative values can be corrected *a posteriori*. When isotope species are simultaneously modelled, however, the occurrence of negative values must be avoided because of resulting dramatic inconsistencies in isotopic ratios (preliminary tests have shown that values up to 10^8‰ are easily generated). In the present simulation, horizontal transport is modelled, using a first-order upstream flux form. All isotope species are, therefore, transported consistently in horizontal directions. The upstream scheme is strongly diffusive along the flow streamlines, but it has the advantage of producing more coherent precipitation patterns when it interacts with convective parameterizations. However, this upstream scheme cannot be applied in the vertical direction because it would lead to an unrealistically humid stratosphere. Vertical transport of water vapour is, therefore, modelled using a second-order flux form based on harmonic means between neighbouring points[23]; this scheme is not diffusive and ensures positive values of the water vapour mixing ratio. The fluxes of HDO and $H_2{}^{18}O$ are computed from the product of the water vapour flux and the arithmetic means of isotopic ratios. This technique ensures a consistent treatment of all isotope species and keeps isotopic ratios within reasonable bounds[12,13]. More elaborate methods, such as 'flux corrected techniques'[29], should also be considered for future simulations.

The LMD AGCM distinguishes two kinds of condensation processes, large-scale condensation and small-scale convection[16]. The first case occurs when the air is supersaturated and the temperature lapse rate is less than the moist adiabatic lapse rate (non-convective clouds). Water vapour is condensed and temperature rises due to the release of latent heat until the mixing ratios reach the saturation value at the new temperature. Supersaturation is then tested downwards, starting from the top layer, and condensed water vapour is eventually re-evaporated in the next layer down when the air is undersaturated. The second case occurs when the air is conditionally unstable, with a temperature lapse rate exceeding the moist adiabatic lapse rate (convective clouds). For supersaturated air, the moist convective adjustment technique[30] is used: the temperature is adjusted to the previous estimate of the moist adiabatic lapse rate, with energy being conserved in the process over the whole unstable range. The mixing ratios are then set equal to saturation values at the adjusted temperature and the excess precipitates. For unsaturated layers, condensation may occur in moisture convergence areas. Here we follow Kuo's parametrization[31] of cumulus convection: we assume a moist adiabatic profile within the cloud with a moist static energy equal to its saturation value at cloud base, that is at the top of the mixed layer; the fractional area occupied by the cloud is determined as the ratio of latent heat available from moisture convergence at cloud base, to the energy necessary to generate the whole cloud on the mesh size. Temperature and humidity are then homogenized within the mesh, and the excess of moisture precipitates. In the present simulations, precipitating water re-evaporates under convective cloud base until the air becomes saturated.

At each phase change, isotopic fractionation is modelled[21] according to the type of phase change and the nature of the phase formed. Two phase transitions can lead to ice formation: direct deposition of vapour onto a solid phase, which actually occurs below −15 °C, and the freezing of liquid droplets. In the first case, as the molecular exchanges are very slow inside solid crystals, the classical Rayleigh or open system model is assumed[32]: the condensed phase is immediately removed after its formation and leaves the air parcel in isotopic equilibrium with the vapour phase. The second case occurs between −15 and 0 °C without any isotopic fractionation, since, whatever their size, the freezing time of droplets and drops is negligible in comparison with their isotopic relaxation time[31]. The case of liquid formation, above −15 °C, is more difficult to model: the Rayleigh model is more reasonable for drops, as their isotopic relaxation time is large[32], while the closed system model, which assumes isotopic equilibrium between all the condensed phase and the vapour, is more adequate for droplets. Indeed, an accurate model[34] should take into account the isotopic interactions between the water species coexisting in a cloud (vapour, cloud water, rainwater, cloud ice and graupel), the partial removal of precipitation and the variations with time of these parameters. Instead, we have chosen the two extreme hypotheses (open and closed system) by performing two parallel experiments (B and A respectively) in which one of the two assumptions is used. During evaporation, we simply assume no fractionation for solid water, because the molecular exchanges are extremely slow, and isotopic equilibrium for liquid water, which is a reasonable approximation when liquid water is mainly composed of droplets with a radius <100 μm (ref. 33).

The parameterization of convective clouds presently used in the LMD AGCM only provides the total change of water vapour mixing ratio at each layer without separating convective diffusion from condensation. For isotope modelling[21], however, we need to separate the two processes. We assume an intermediate step where water vapour and all isotope species are uniformly mixed throughout the vertical extension of the cloud; this assumption, associated with the cloud budget already computed, uniquely determines the vertical distribution of condensation. This seemingly excessive vertical diffusion is, in fact, compensated by intensive condensation in the upper cloud layers, associated with re-evaporation in the lower cloud layers (in this step isotopic equilibrium between liquid and vapour is assumed at the end of the process). Another necessary parameter is the fractionation coefficient at the location of phase changes. To take into account the complexity of convective diffusion, we define the fractionation coefficient as the arithmetic average of its 'initial' value (determined by the temperature at the source regions—mainly cloud base) and its final value (determined by the final temperature of the layer). This scheme was first tested on isolated clouds. It yields acceptable results but with a

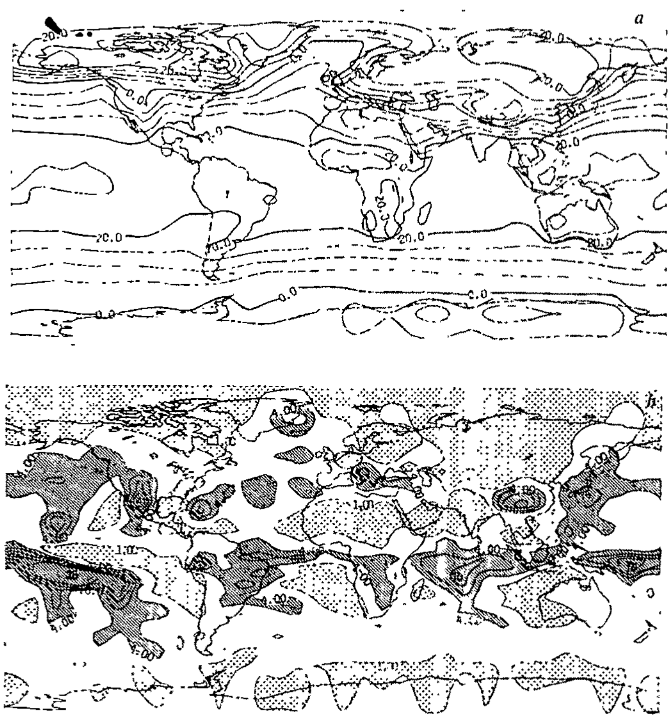

Fig. 1 Mean January simulated: *a*, surface-air temperature (°C; isolines every 5 °C); *b*, precipitation. Isolines every 3 mm day^{-1} up to 16 mm day^{-1}; dotted areas, <1 mm day^{-1}; hatched areas, >4 mm day^{-1}.

tendency to systematically underestimate isotopic ratios at cloud top; this effect, however, is not too serious because it is noticeable only when clouds extend up to higher tropospheric levels where mixing ratios are, in any case, small.

Usually the supersaturation S with respect to the liquid phase is <1% in clouds[35] and so kinetic effects are completely negligible. However, they may become important when S is far from zero. This occurs in the case of snow crystal formation, where the supersaturation S with respect to the solid phase may reach values up to 20% (ref. 36). During re-evaporation, kinetic effects are negligible for droplets but become important for drops[32], which prevail mainly in precipitating water from convective clouds. Kinetic effects at snow formation can be simply parameterized using an equivalent fractionation coefficient α_e (ref. 10) which is a decreasing function of S; therefore, compared with equilibrium values, they tend to decrease the enrichment of falling snow and to enhance their δD–δ^{18}O slope. Inclusion of these effects in a dynamically simple model leads to predicted snow isotopic values in very good agreement with observed values in polar areas, both concerning the isotope–temperature and δD–δ^{18}O relationships[10]. To test the impact of kinetic effects on snow formation with our isotope modelling[23], we introduced these effects on snow formation with clouds below −15 °C in only one experiment (experiment B); however, the supersaturation function used $S = 0.906 \exp(-0.008\, t_c)$, t_c being the condensation temperature in °C, is slightly lower than the one leading to the best agreement between observed and predicted isotopic ratios over East Antarctica[10]. Kinetic effects during re-evaporation of drops lead to a further enrichment of precipitating water[37,38] and to a decrease of the δD–δ^{18}O slope[1]. The formulation used to model these effects[23] is based on the treatment developed by Stewart[37] for a single drop, assuming that stationary δD and δ^{18}O values are reached at the end of re-evaporation; the enrichment increases as the relative humidity decreases. These effects have been introduced for re-evaporation of precipitating water under a convective cloud base in one experiment (B) only; the relative humidity value determining the enrichment of drops is chosen as an average of the initial and final relative humidity values of the layer.

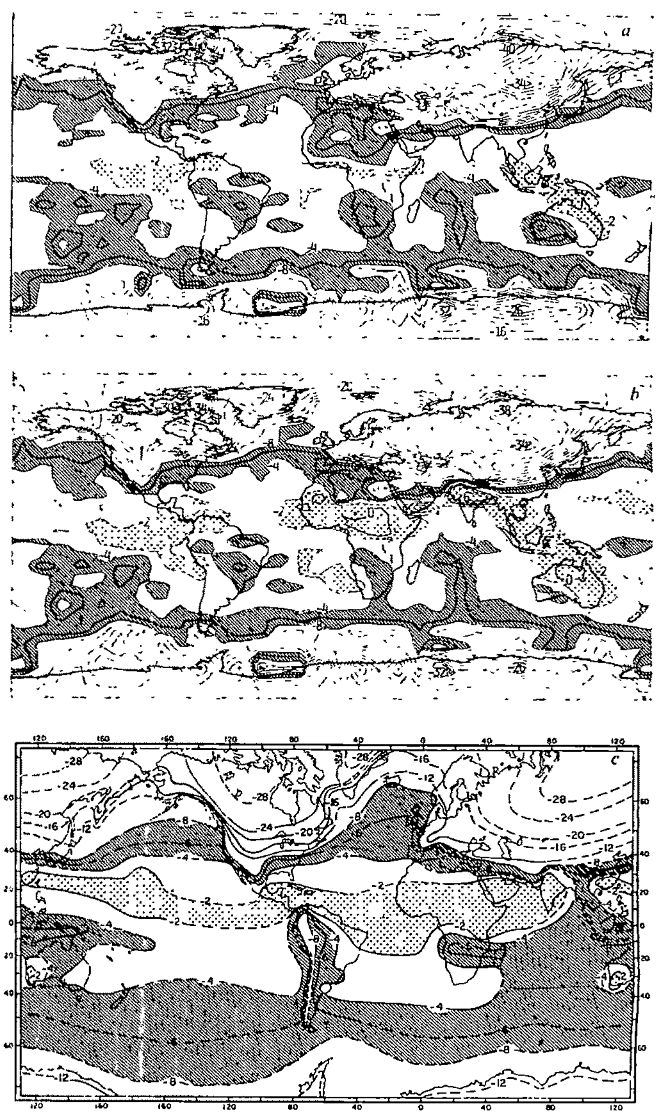

Fig. 2 Mean ^{18}O content of precipitation charts, experiments A(*a*) and B(*b*) for January to be compared with *c*, mean January observations (from J. R. Lawrence, work in preparation). Isolines every 2‰, for *c* isolines every 4‰ below −8‰; dotted areas, >−2‰; hatched areas, between −8 and −4‰.

Numerical experiment

The preliminary tests of isotope modelling described here have been performed with a low-resolution version of the LMD AGCM: 32 points in longitude, 24 points in latitude, 11 levels, which corresponds to a horizontal mesh size of the order of 800 × 800 km^2 around 50° and 1,250 × 450 km^2 at the Equator. The numerical experiment was a simulation of the present day January climate. Initial values of atmospheric and ground variables were taken from an earlier January simulation. The initial values for vapour isotopic ratios were chosen as constant in the whole atmosphere and smaller than the observed values (−80‰ for $H_2{}^{18}O$ and −600‰ for HDO, that is a deuterium excess of 40‰). Surface isotope ratios were set initially at the climatological mean precipitation ratios deduced from the local surface-air temperature[1]. During all the simulation, the oceanic surface-isotopic ratio was prescribed at 0‰ for both isotopes. All results presented here are averages over the last 20 days of this 80-day run.

The climatology of the present experiment is reasonably realistic, although it suffers from the coarse horizontal resolution. The surface-air temperature pattern (Fig. 1*a*) is well simulated, especially in the tropics[39]. The continental gradients in the Northern Hemisphere are realistic. However, the high-latitude temperatures in both hemispheres are markedly too warm, a defect common to all AGCMs but possibly emphasized by the low resolution used here; the particularly strong warming observed over north east Siberia is clearly associated with the low CLIMAP surface albedo value in this area. In the precipitation field (Fig. 1*b*), the Inter-Tropical Convergence Zone is fairly well resolved, with realistic values of 6–10 mm day^{-1} (ref. 40), except for the Pacific branch which is underestimated and slightly shifted to the north, associated with a strongly developed South Pacific Convergence Zone with values up to 28 mm day^{-1}. These anomalous Pacific features have been noticed in other numerical experiments, using the same model; they correspond to a transient episode in the model climatology. In middle latitudes, the coarse resolution of the model yields a systematic underestimation of baroclinic instability processes and the associated low pressures and rainfall, especially in the 'roaring forties'. A related defect is an underestimation of the extent of the subtropical dry regions associated with very weak high pressures.

Concerning the isotopes, we shall mainly discuss experiment A (involving the closed-system assumption for liquid formation and no kinetic fractionation, except for evaporation at the ocean–air interface) and mention experiment B (involving the open system assumption for liquid formation and kinetic fractionation) only when major differences between A and B are observed.

Figure 2*a* displays the 20-day average ^{18}O content of precipitation as simulated by experiment A. We observe a good agreement with January mean observations (Fig. 2*c*), with high ratios in the tropics and a decrease with increasing latitude modulated by a Northern Hemisphere planetary wave pattern. In middle to high latitudes, Figs 1*a* and 2*a* clearly show the expected positive correlation between δ^{18}O and temperature fields, low ratios being associated with low temperatures. When we look into geographical distributions in more detail, we have to be cautious because the rather large variability in space and time tends to limit the significance of 20-day averages; moreover, observations are missing in some areas (dashed contour lines on Fig. 2*c*). In middle latitudes, the simulated ratios are quite realistic, with values in the −8, −14‰ range in Western Europe for example. In higher latitudes, simulated ratios down to −40‰ are obtained in the coldest areas (−20, −25 °C). The accuracy of the model is not easy to verify there because observations are scarce: for instance, in Yakutsk, the simulated ratio is around −30‰ against an observed value of −34‰ (ref. 41) in December; but in Fort Smith and Edmonton, the model yields −20‰ against a range of January values from −25 to −33‰ (refs 42–47). Thus we may overestimate isotopic ratios at some locations in higher latitudes. This is especially true over ice sheet: in Greenland, our minimum simulated ratio is −22‰ whereas winter values registered in recent snow can be down to −40‰ (ref. 48); over the Antarctic Plateau, the minimum simulated value is −32‰ compared with observed values of −40 to −55‰ (refs 2, 49–51). This tendency to overestimate isotopic ratios is partially related to the unrealistic warming already observed in the model climate at high latitudes; but the values obtained over Siberia, for instance, show that the correlation between isotope and temperature biases may be disturbed by other factors such as fluctuations or biases in the origin and path of air masses. In middle to high latitudes, experiment B tends to simulate lower isotopic ratios with a difference down to −4‰, probably induced by kinetic fractionation during formation of snow crystals, as will be seen with the analysis of deuterium excess.

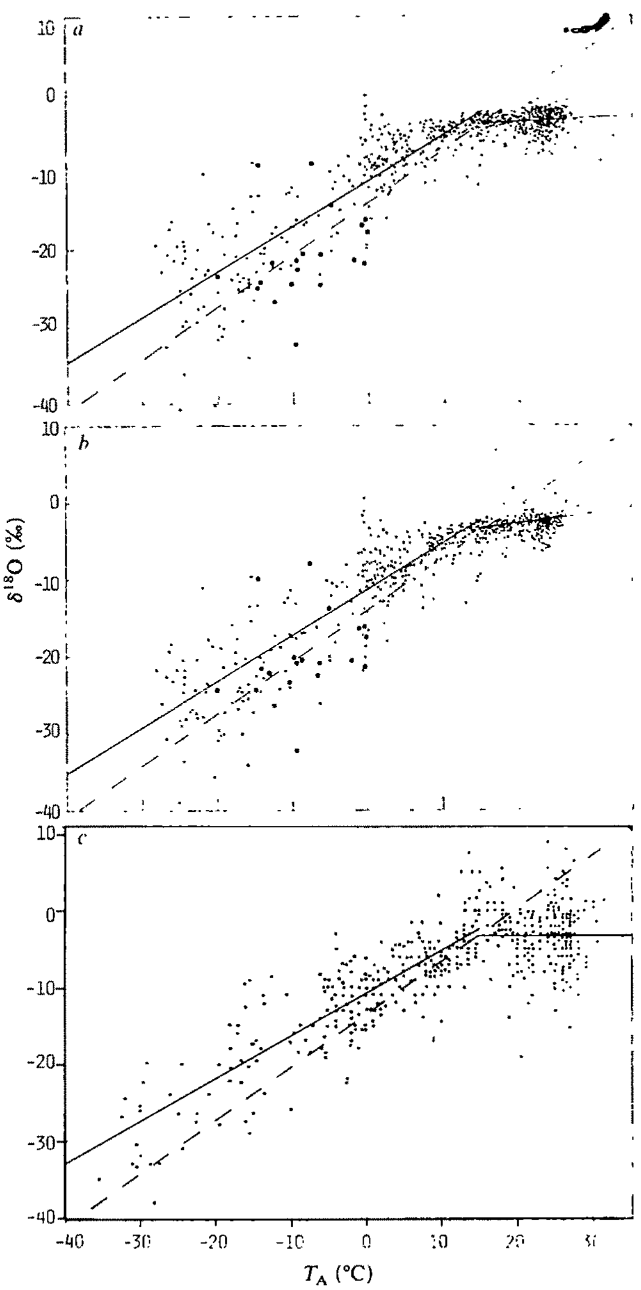

Fig. 3 Mean ^{18}O content of precipitation as a function of mean surface-air temperature, experiments A (*a*) and B (*b*) to be compared with *c*, monthly mean observations for January from the IAEA network[42–47]. Solid lines, regression lines for $T_A < 15$ °C: *a*, $\delta^{18}O = 0.59\ T_A - 11.1$, $r = 0.86$ (correlation coefficient); *b*, $\delta^{18}O = 0.60\ T_A - 11.5$, $r = 0.87$; *c*, $\delta^{18}O = 0.55\ T_A - 10.7$, $r = 0.85$. For $T_A >$ 15 °C: *a*, $\delta^{18}O = 0.05\ T_A - 4.6$, $r = 0.12$; *b*, $\delta^{18}O = 0.13\ T_A - 5.6$, $r = 0.22$; *c*, $\delta^{18}O = 0.006\ T_A - 3.4$, $r = 0.007$. Dashed line, Dansgaard's observations[1]: $\delta^{18}O = 0.69\ T_A - 13.6$. Simulated Antarctica and Greenland grid point values are identified (large dots).

In the tropics, where there is little variation in temperature, the simulated δ^{18}O field exhibits a strong spatial variability, further enhanced in experiment B. These patterns are closely correlated to the precipitation field (Fig. 1*b*). Dansgaard[1] has already observed this 'amount effect' in tropical data sets and explained it on the one hand, by an enrichment of precipitation ratios in regions of undersaturated air or low precipitation rates, and on the other hand, by an impoverishment of water vapour in regions of intensive condensation or high precipitation rates. The first mechanism is confirmed by comparing experiments A and B: in experiment B, higher ratio regions correspond to higher enrichment by kinetic fractionation during re-evaporation under cloud base (this interpretation is corroborated by the comparative analysis of deuterium excess). Note that the closed or open system assumptions during liquid formation do not seem to have any appreciable impact on the results. More quantitatively, the simulated results are in good agreement with observations with ratios down to −4, −10‰ for high precipitation rates and up to 0–1‰ for low precipitation rates[41]. The best agreement is with experiment B, which corroborates the importance of kinetic fractionation during re-evaporation under cloud base: simulated ratios as high as 6‰ may seem to be overesti-

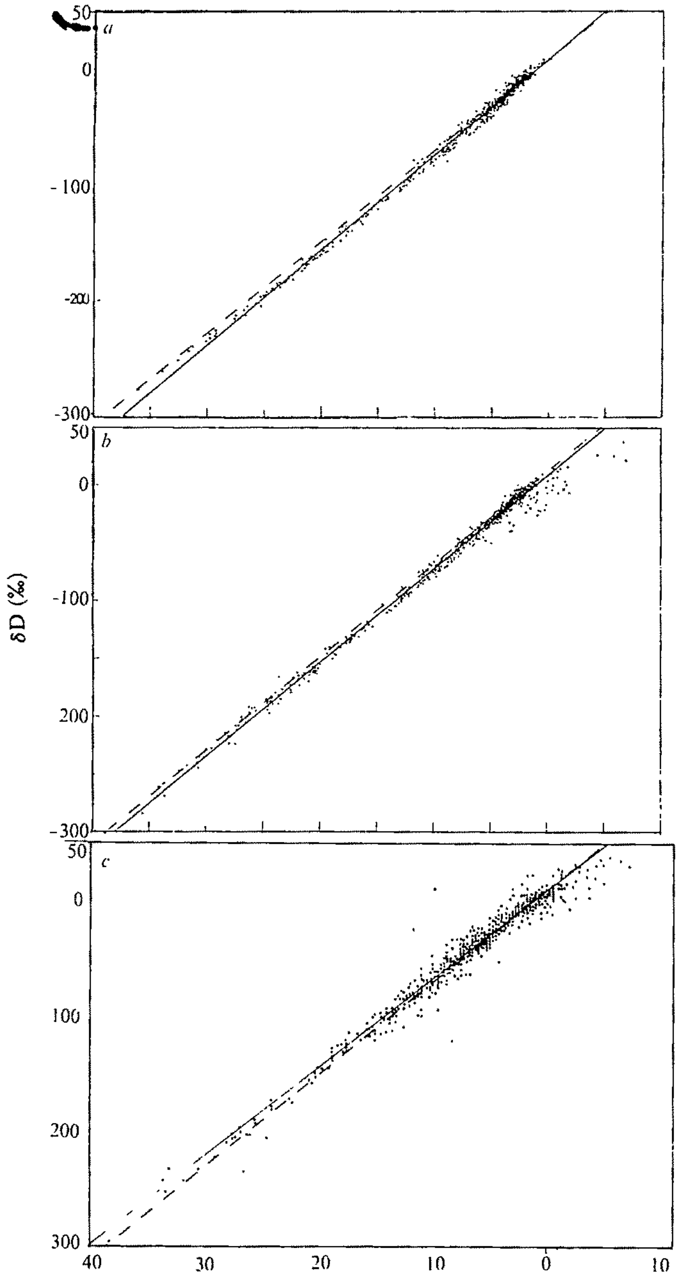

Fig. 4 Mean ^{18}O content of precipitation as a function of mean D content of precipitation, experiments A (*a*) and B (*b*) to be compared with *c*, monthly mean observations for January from the IAEA network[42–47]. Solid lines, regression lines: *a*, $\delta D = 8.3\ \delta^{18}O + 11.2$, $r = 0.99$; *b*, $\delta D = 8.0\ \delta^{18}O + 8.3$, $r = 0.99$; *c*, $\delta D = 7.7\ \delta^{18}O + 8.5$, $r = 0.98$. Dashed line, Craig's observations[6]: $\delta D = 8\ \delta^{18}O + 10$.

mated, but ratios around 8‰ are actually observed, for example, in Bamako in February or in Adelaide in January[41–47]. Major discrepancies with observations come mainly from a displacement of some precipitation patterns in the model's climatology, for example, in central Indonesia and northern Australia, where our 20-day average 'climate' happens to be drier than normally observed and the simulated isotopic ratios are consequently higher than observed, or in the southern Pacific. Note that the dispersion in the $\delta^{18}O$–precipitation relationship can be important; in some observations[41–47], or in simulated results over Australia, a positive correlation with precipitation can even occur locally. This feature probably reflects the impact of atmospheric circulation patterns on isotope contents of precipitation; simulated results over Australia are quite similar to observations in 1973, but differ from mean observations. It would be hazardous, however, to explain all our isotope deficiencies by model climatic drifts. To test our isotope modelling, we need to investigate in greater detail the dependency of ^{18}O content of precipitation on both temperature and precipitation; the impact of atmospheric circulation patterns will be roughly deduced.

Figure 3*a*, *b* shows a good correlation between surface-air temperature and the 20-day average ^{18}O content of precipitation simulated in experiments A and B respectively; Fig. 3*c* displays the corresponding monthly average observed field for January, extracted from IAEA data over the 1953–75 period[42–47]. At temperatures <15 °C, the correlation is quite significant in all of Fig. 3, with correlation coefficients around 0.85. The simulated and observed regression lines and dispersions are also quite similar. The differences noted in the geographical charts between experiments A and B do not affect the $\delta^{18}O$–temperature relationship. This seems to contradict earlier conclusions obtained from simple models[10,32], which do not, however, include dispersion effects such as the origin and path of air masses; the reason could also be that the model produces temperatures that are too warm and a relatively large proportion of convective precipitation in polar areas, thus underestimating the importance of kinetic effects during formation of snow crystals, which are taken into account in non-convective systems only and for snow formed below −15 °C. Dansgaard's[1] linear relation between $\delta^{18}O$ and temperature below 15 °C has also been plotted in Fig. 3. We observe that both IAEA-observed and simulated ratios are, on average, higher than Dansgaard's values, with an increasing discrepancy in colder regions. Dansgaard's data are more reliable at high latitudes where IAEA stations are scarce; the low values he obtained there have been confirmed by more recent studies[2,52]. Note that all ice cap data to which we refer[1,2,48,52] concern annual means; for Antarctica, the displacement could be further enhanced when considering January values[49,50]. These relatively low values over polar regions (Antarctica and Greenland) associated with an enhanced dependency on temperature could be due to (1) increased distance from water isotope source regions, inducing a larger amount of fractionation processes, and (2) altitude, which causes precipitations to originate from higher tropospheric levels. Such a systematic polar cap effect is actually simulated by the model as can be seen by the large dots on Fig. 3*a*, *b*, corresponding to Antarctica and Greenland grid point values; these values are indeed close to ice cap data[48]. It is, however, difficult to assess the efficiency of our isotope modelling in these regions as temperatures there are systematically too high.

At temperatures above 15 °C, both correlation and dependency on temperature totally disappear in observed data and decrease strongly in our simulation. The weakening of the temperature–isotope relation is mainly due to the predominance of convective systems, accompanied by intense mixing of water originating from different layers. The dispersion (further enhanced in experiment B by kinetic effects under cloud base) mainly reflects dependency on precipitation amount. The general dependency of $\delta^{18}O$ on precipitation for temperatures higher than 15 °C clearly appears on both experiments with correlation coefficients around −0.4 and simulated regression lines: $\delta^{18}O = -0.50P - 2.8$ for experiment A and $\delta^{18}O = -0.79P - 2.0$ for experiment B, with $\delta^{18}O$ in ‰ and precipitations P in 100 mm per month. The results of experiment B are in particularly good agreement with January mean observations: $\delta^{18}O = -0.93P - 1.8$ with a similar correlation coefficient. This again pinpoints the importance of kinetic fractionation during re-evaporation under cloud base.

Deuterium content of precipitation has similar dependencies on temperature and precipitation; therefore, at this stage, we just need to study its relation with ^{18}O content of precipitation (Fig. 4*a*, *b*, *c*). Correlation is high in all of Fig. 4, with correlation coefficients around 0.98. The simulated ratios are in close agreement with observations and their dispersion around Craig's meteoric water line[6] $d = \delta D - 8\delta^{18}O = 10‰$ is similar. In the high ratio range, the observed decrease in slope and increase in dispersion (Fig. 4*c*) is well simulated only by experiment B: this supports the importance of kinetic fractionation during re-evaporation under cloud base[1]. In the low ratio range, experiment B with kinetic fractionation during snow crystal formation shows a better agreement with observations, with a slightly greater δD–$\delta^{18}O$ slope than in experiment A. Although they have a smaller amplitude, these features corroborate simple model results[10].

Conclusion

We have presented the first simulation of the atmospheric cycles of HDO and $H_2{}^{18}O$. Many features of our simulations are in good agreement with real conditions. Most of the differences we have observed on geographical charts seem mainly due to local differences between simulated and observed climate; this is confirmed by the fact that the $\delta^{18}O$–temperature, $\delta^{18}O$–precipitation and δD–$\delta^{18}O$ relations are realistically simulated. The use of higher resolution in future experiments will improve the climatology of the model and, therefore, many aspects of the isotope simulations. The model in its present form looks accurate enough to be used for palaeoclimatic reconstructions.

This work was supported by the Programme National de la Dynamique du Climat. We thank L. Merlivat (LGI) for helpful discussions, J. R. Lawrence (Lamont Doherty Geological Observatory) for providing the geographical chart of mean observed January ^{18}O content of precipitation, M. Fonchon (LMD) for developing the graphics and M. Gangloff (LMD) for processing CLIMAP data. We particularly thank P. Le Van (LMD) for his essential contribution to the programming work.

Molecular cloning of the transforming gene from a chemically transformed human osteosarcoma-derived cell line enables the gene to be mapped to chromosome 7 (7p11.4–7qter) and by this criterion and by direct hybridization to be shown to be unrelated to known oncogenes.

DOMINANT transforming genes have been detected in several different types of chemically induced tumours and in cells transformed *in vitro* by chemical carcinogens. Many of the transforming genes identified in these studies were members of the *ras* family of oncogenes. Cellular homologues of the oncogene of Harvey sarcoma virus (*ras*^{H}) were activated in chemically induced squamous cell carcinomas and papillomas in mice[1,2], chemically induced mammary tumours in rats[3] and guinea pig cells transformed *in vitro* by chemical carcinogens[4]. Similarly, cellular homologues of the oncogene of Kirsten sarcoma virus (*ras*^{K}) were activated in 3-methylcholanthrene-induced mouse sarcomas[5] and in mouse fibroblasts[6] transformed *in vitro* by chemical carcinogens. A third member of the *ras* gene family (*ras*^{N}) was activated in chemically induced thymic lymphomas of mice[7]. Studies of these systems should reveal the mechanisms of activation of *ras* genes by classes of chemical carcinogens

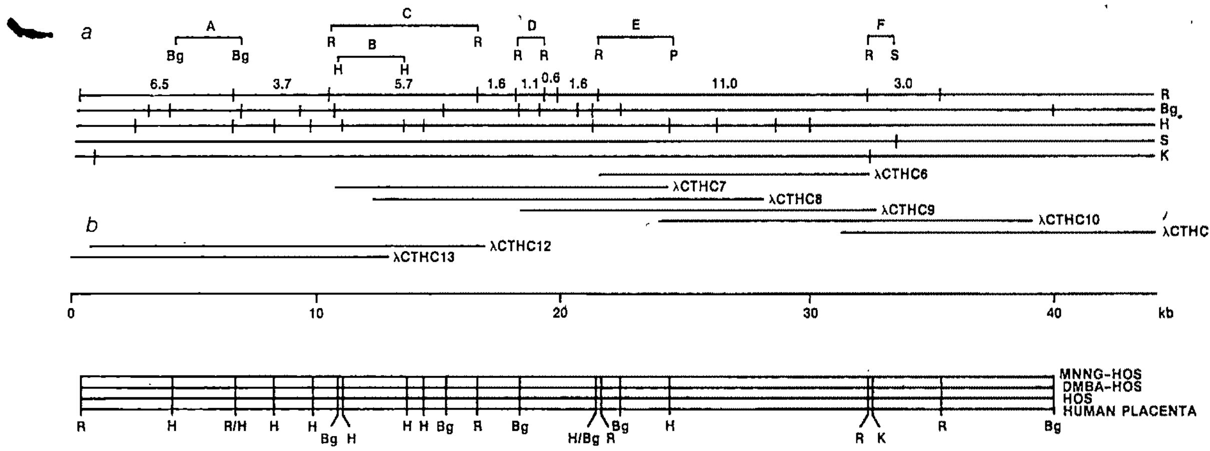

Fig. 1 *a*, Transforming DNA sequences of MNNG–HOS cells. An 11.0-kb human DNA fragment present in *Eco*RI-digested DNA from a MNNG–HOS secondary transfectant (λCTHC6) was cloned from a library constructed in the λgtWES cloning vector. Phage libraries were constructed by the method of Hohn and Murray[49]. The library was screened, without prior amplification, by the method of Benton and Davis[50] using Blur8 plasmid DNA[18] which was labelled with ^{32}P by nick-translation[51] as a probe. The 11.0-kb *Eco*RI fragment was subcloned into pBR322 and the subclone was used as a probe to isolate recombinant DNA clones (λCTHC7–11) that contained adjacent DNA sequences from a second library. The latter was constructed by first partially digesting DNA from an MNNG–HOS transfectant with *Sau*3A and then introducing the partially digested DNA into the EMBL3 cloning vector[52]. Clones λCTHC-12 and -13 were isolated from the same EMBL3 library using a probe prepared from a restriction fragment (fragment B) produced by digesting λCTHC7 with *Hin*dIII. A restriction map of the cloned cellular DNA is presented. Six specific restriction fragments (fragments A–F) were subcloned into pBR322. The sizes in kilobases of the *Eco*RI fragments are indicated. *b*, Partial restriction maps of the gene present in human placenta, MNNG–HOS cells, DMBA–HOS cells and HOS cells. The maps were determined from the results of hybridization analysis in which restriction fragments A–F (*a*) were used to detect related sequences in human DNAs that had been digested either with *Eco*RI, *Hin*dIII and *Bgl*II or with *Kpn*I and *Bgl*II. DNAs were prepared exactly as described previously[16], digested with three to fivefold excess of restriction enzyme, electrophoresed in agarose (1% w/v) gels and blotted onto nitrocellulose as described by Southern[17]. Filters were hybridized to DNA fragments labelled with ^{32}P by nick translation[51], in stringent conditions (50% formamide, 5×SSC, 42 °C) for 24 h and washed with a final stringency of 0.2×SSC at 68 °C. Restriction endonucleases used were *Eco*RI (R), *Bgl*II (Bg), *Hin*dIII (H), *Sal*I (S), *Kpn*I (K) and *Pst*I (P).

which, as environmental and dietary contaminants, are suspected of contributing to the incidence of cancer in man[8–10].

In contrast to the abundance of studies on chemically transformed rodent cells, there are only a few reported examples of human cells transformed by direct treatment with chemical carcinogens[11–14]. The transformation of human fibroblasts[11] and human osteosarcoma (HOS)[12,13] cells by chemical carcinogens *in vitro* has been reported and in initial studies we examined the ability of DNA prepared from these chemically transformed human cell lines to transform NIH 3T3 cells[15,16]. Our results showed that DNA from a HOS cell line that had been chemically transformed *in vitro* with *N*-methyl-*N*′-nitro-*N*-nitrosoguanidine (MNNG)[12] could transform NIH 3T3 cells. In contrast, DNA from 7,12-dimethylbenz(*a*)anthracene (DMBA) transformed HOS cells[13], parental HOS cells or 4-nitroquinoline-1-oxide transformed human fibroblasts (HUT14) did not transform NIH 3T3 cells[15], suggesting that MNNG may have caused genetic alterations in HOS cells that gave rise to a transferable transforming gene. Recently, we have demonstrated that this transforming gene is not a member of the *ras* family of genes[16], and we now report the molecular cloning of the MNNG–HOS transforming gene, its comparison with known oncogenes and its human chromosomal localization.

Molecular cloning

High molecular weight DNA from MNNG–HOS cells can efficiently transform mouse NIH 3T3 cells, and DNA from the transformed NIH 3T3 cells (primary transfectants) can be used in a second round of transfection to induce secondary transfectants[15,16]. Southern analysis[17] of *Eco*RI-digested transfectant DNA with a probe specific for human highly repeated *Alu* DNA sequences (Blur8)[18] showed that the secondary transfectants contained conserved human *Eco*RI DNA fragments of 11.0, 5.7 and 3.7 kilobases (kb). This observation suggested that these three human DNA fragments are closely associated with the transforming gene. In our strategy for the molecular cloning of the MNNG–HOS transforming gene, we first used the probe specific for human highly repeated DNA sequences to isolate the 11.0-kb *Eco*RI DNA fragment. The 11.0-kb human DNA fragment present in *Eco*RI-digested DNA from an MNNG–HOS secondary transfectant was enriched by centrifugation through a sucrose gradient and cloned into the EK2 vector λgtWES. From a library of 400,000 recombinant phage, we obtained one isolate (λCTHC-6, Fig. 1*a*) that possessed human repeated DNA sequences and contained an 11.0-kb *Eco*RI DNA fragment.

Regions of the transforming gene which were adjacent to the 11.0-kb *Eco*RI fragment were isolated from a library obtained using DNA from an MNNG–HOS secondary transfectant. The DNA was first partially digested with *Sau*3A and then cloned into the EMBL3 cloning vector. A library of 2×10^6 recombinant phage was amplified and phage that contained regions of the transforming gene immediately adjacent to the 11.0-kb *Eco*RI fragment were isolated from portions of the amplified library using the cloned 11.0-kb *Eco*RI human DNA fragment as a probe. More distant regions of the transforming gene were isolated in genomic library 'walking' experiments (Fig. 1*a*). Figure 1*a* shows restriction map of 44 kb of cellular DNA present in seven recombinant clones isolated from the library.

To determine which parts of the cloned DNA represented the MNNG–HOS transforming gene, the λ clones (λCTHC6–13) and specific restriction fragments (fragments A–F, Fig. 1*a*) were used as probes in Southern analyses[17] to detect related sequences in DNA from MNNG–HOS secondary transfectants. The results of these analyses indicated that 26 kb of DNA which includes *Eco*RI human DNA fragments of 11.0, 5.7, 3.7, two 1.6, 1.1 and 0.6 kb (Fig. 1*a*) is part of the transforming gene, as these DNA sequences are invariably present in DNA from MNNG–HOS secondary transfectants. For example, probes prepared from the cloned 11.0-kb *Eco*RI fragment present in λCTHC6 and from fragment D (Fig. 1*a*) both detected an 11.0-kb DNA fragment in *Eco*RI-digested genomic DNA from secondary transfectants. In contrast, the 3.0- and 6.5-kb *Eco*RI fragments that occur respectively at the right and left ends of the cloned DNA (Fig. 1*a*) were not detected in all of the secondary transfectants. Thus, the data presented in Fig. 3 show that a probe prepared from λCTHC10 only detected the 3.0-kb *Eco*RI DNA fragment in two of the four secondary transfectants. In addition, the results of similar studies in which λCTHC13 was used as a probe showed that only 7 of 10 secondary transfectants examined contained the 6.5-kb DNA fragment (data not shown). When taken together, these observations indicate that the 6.5- and 3.0-kb *Eco*RI DNA fragments contain flanking DNA sequences that can be removed during transfection without affecting the activity of the MNNG–HOS transforming gene.

In transfection experiments, when examined individually, none of the λ clones (λCTHC6–13) could transform NIH 3T3 cells. However, this result was not unexpected as each clone contains only part of the transforming gene. Examination of the biological activity of the cloned MNNG–HOS transforming gene must await the reconstruction of the intact gene.

Arrangement of the MNNG–HOS gene

To determine whether the transforming gene was rearranged in MNNG–HOS cells, portions of the cloned gene (Fig. 1*a*, fragments A–F) were used as probes to detect related sequences in DNA prepared from several different human cell lines and from human placenta. A probe prepared from an *Eco*RI–*Pst*I restriction fragment (fragment E, Fig. 1*a*) hybridized to an 11.0-kb DNA fragment in *Eco*RI-digested human placental DNA (Fig. 2*B*, lane *h*), as well as DNA prepared from other human cell lines (Fig. 2*B*, lanes *f*, *g*, *i*–*m*). Data obtained in this experiment and in other Southern analyses of DNA digested either with *Eco*RI, *Hin*dIII, *Bgl*II and *Kpn*I or with *Kpn*I and *Bgl*II allowed us to construct partial restriction maps of the related DNA sequences present in human placenta, MNNG–HOS cells, DMBA–HOS cells and HOS cells. The partial restriction maps obtained for all four human DNAs are identical and are shown in Fig. 1*b*. Thus, at this level of resolution there are no detectable rearrangements of these DNA sequences in the MNNG–HOS cell line.

Relationship to oncogenes and location

We reported previously that the MNNG–HOS transforming gene is not a member of the *ras* family of oncogenes[16]. Hybridization of the cloned MNNG–HOS transforming gene to cloned viral and cellular oncogenes confirmed this result and also showed that the transforming gene is not homologous by DNA hybridization to *mos*, *myc*, *myb*, *src*, *sis*, *rel* and *Blym* (data not shown). Furthermore, the restriction map of the MNNG–HOS transforming gene is not the same as those of *ras*$^{\mathrm{N}}$ (refs 19, 20) and *Blym* (ref. 21) or of the human homologues of *ras*$^{\mathrm{H}}$ (ref. 22), *ras*$^{\mathrm{K}}$ (ref. 19), *mos* (ref. 23), *myc* (ref. 24), *abl* (ref. 25), *sis* (ref. 26) and *fes* (ref. 27).

As a further characterization of the MNNG–HOS gene, we determined its human chromosomal location. Southern analysis of DNA from 12 different rodent–human somatic cell hybrids containing unique complements of human chromosomes (Table 1) was used to determine the chromosomal location of the MNNG–HOS transforming gene. Cell hybrids were characterized by karyotype analysis and by expression of isozyme markers that have been previously assigned to each of the human chromosomes[28–31]. DNA prepared from each cell hybrid was digested with *Hin*dIII and subjected to Southern analysis using the *Eco*RI–*Pst*I DNA fragment (fragment E, Fig. 1*a*) as a probe. In stringent conditions of hybridization, probe E detects a single 3.2-kb human *Hin*dIII restriction fragment (Fig. 4*A*, lanes *g*, *i*) but does not hybridize to rodent DNA (Fig. 4*A*, lane *h*). Figure 4 gives examples of these analyses while Table 1 shows the human chromosome complement of the hybrid cell lines and the results obtained when the DNAs from these hybrids were scored for the presence of the 3.2-kb *Hin*dIII restriction fragment. The results are consistent only with assignment of the MNNG–HOS transforming gene to chromosome 7. To refine this initial result, we have analysed a human–mouse hybrid cell line (53-87-3 c136 is c12 sub7) which retains only the portion of human chromosome 7 from 7p11.4 to 7qter (ref. 30) and has

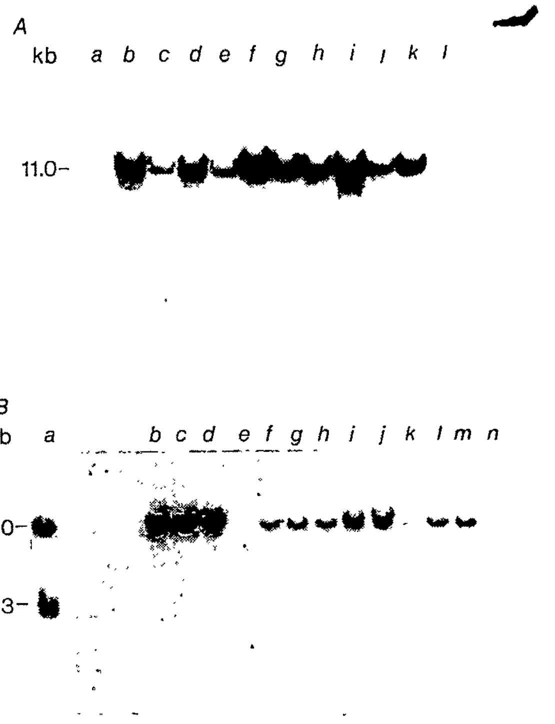

Fig. 2 Hybridization of human DNA and DNA from MNNG–HOS secondary transfectants to cloned DNA sequences. *A*, 10 μg of each DNA (lane *a*, NIH 3T3; lanes *b*–*l*, independent MNNG–HOS secondary transfectants) was digested with *Eco*RI, subjected to electrophoresis in agarose gels (0.8 w/v) and transferred to a nitrocellulose filter as described by Southern[17]. The filters were hybridized (50% formamide, 5×SSC, 42 °C) for 21 h to a ^{32}P-labelled probe that was prepared from the 11.0-kb *Eco*RI restriction fragment present in clone λCTHC6 (Fig. 1*a*) by nick translation[51]. The 11.0-kb *Eco*RI restriction fragment was first subcloned into pBR322. The plasmid DNA was digested with *Eco*RI and the 11.0-kb restriction fragment was purified by electrophoresis in agarose gels. *B*, 10 μg of each DNA (lane *a*, NIH 3T3 DNA containing 5 genomic equivalents of the 11.0-kb *Eco*RI restriction fragment cloned into pBR322; lanes *b*–*d*, independent MNNG–HOS secondary transfectants; lane *e*, NIH 3T3; lane *f*, DMBA–HOS[16]; lane g, MNNG–HOS[16]; lane *h*, HOS[16]; lane *i*, human placenta; lane *j*, human fibrosarcoma HT1080 (ref. 15); lane *k*, human teratocarcinoma, PA1 (ref. 16); lane *l*, human nasopharyngeal carcinoma; lane *m*, Wilms' tumour; lane *n*, human fibrosarcoma NF-1 (ref. 16)) was digested with *Eco*RI and subjected to Southern analysis as described in *A*. The nitrocellulose filters were hybridized to a ^{32}P-labelled probe prepared from an *Eco*RI–*Pst*I restriction fragment (fragment E, Fig. 1*a*).

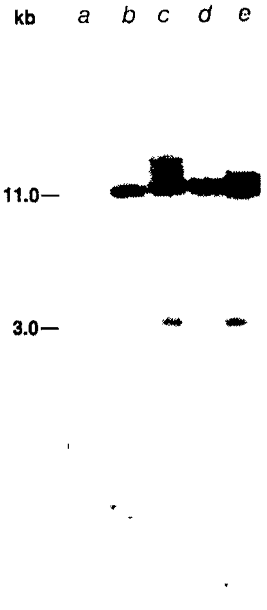

Fig. 3 Hybridization of DNA from MNNG–HOS secondary transfectants to cloned DNA sequences. 10 μg of each DNA (lane *a*, NIH 3T3, lanes *b*–*e*, independent secondary transfectants) was digested with *Eco*RI, subjected to electrophoresis in agarose gels (0.8% w/v) and transferred to a nitrocellulose filter as described by Southern[17]. Filters were hybridized (50% formamide, 5× SSC, 42 °C) for 21 h to a ^{32}P-labelled probe prepared from the recombinant bacteriophage λCTHC10 by nick translation[51].

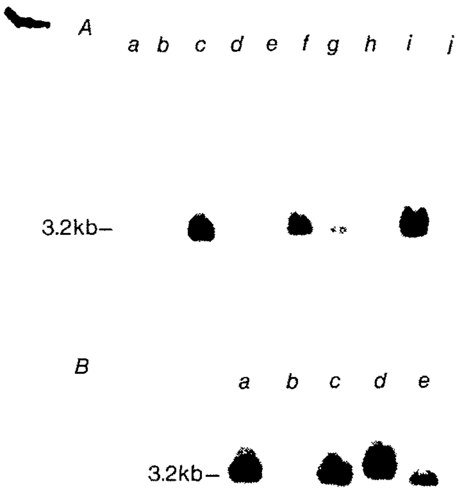

Fig. 4 Hybridization of a probe specific for the MNNG–HOS transforming gene to DNA from rodent–human cell hybrids. *A*, Segregation of the MNNG–HOS transforming gene in rodent–human hybrids. High molecular weight DNA (10 μg) isolated from 77-B10 cl26 (lane *a*), DSK 1B2A5 cl20 (lane *b*), Nude 9 (lane *c*), PAF×BALB IV cl5 (lane *d*), M44 cl2S5 (lane *e*), 53-87-1 cl21 (lane *f*), HL60 human promyelocytic leukaemia cell line (lane *g*), F9 mouse strain 129 teratocarcinoma cell line (lane *h*), JD-38 human Burkitt lymphoma cell line (lane *i*), 706B6-40 cl17 (lane *j*), 77 B10 cl8 (lane *k*) and 77 B10 cl33 (lane *l*) cell lines was digested with a fivefold excess of restriction endonuclease *Hin*dIII, subjected to electrophoresis in 1% agarose gels, then blotted onto nitrocellulose filters. Filters were hybridized in stringent conditions, (50% formamide, 5×SSC, 10% dextran sulphate at 42 °C) for 20 h with ^{32}P-labelled, nick-translated fragment E (Fig. 1*a*). Hybridized blots were exposed to Kodak XAR-5 film at −70 °C in the presence of Kodak intensifier screens for 18 h. *B*, High molecular weight DNA (10 μg) isolated from Ag876II human Burkitt's lymphoma cell line (lane *a*), NP3, BALB/c mouse myeloma cell line (lane *b*), Nude 9 (lane *c*), 53-87-1 cl21 (lane *d*), 53-87-3 cl36 is cl2 sub7 (lane *e*) cell lines was digested with a fivefold excess of *Hin*dIII and subjected to Southern analysis[17] as described above. The rodent–human cell lines used in these experiments have been described previously[28–31].

lost the distal part of the short arm. This analysis (Fig. 4*B*) shows that hybrids containing only human chromosome 7 (Fig. 4*B*, lane *d*) or only 7p11.4 to 7qter (Fig. 4*B*, lane *e*) have retained the MNNG–HOS transforming gene. Thus, this gene is located on chromosome 7 between 7p11.4 and 7qter.

The localization of the MNNG–HOS transforming gene on chromosome 7 provides additional evidence that this gene is not a human homologue of *ras*$^{\mathrm{H}}$, *ras*$^{\mathrm{K}}$, *fos, mos, myb, myc, raf, abl, fes, src* or *sis*, and does not represent an activated human *ras*$^{\mathrm{N}}$, *Blym* or *myc*$^{\mathrm{N}}$ locus because these human proto-oncogenes are located on different human chromosomes (reviewed in ref. 32). The human homologue of the avian erythroblastosis virus (AEV) transforming gene (*erbB*) has been assigned to chromosome 7 (7pter−7q22)[33]. Because the MNNG–HOS transforming gene is located between 7p11.4 and 7qter, chromosomal assignment could not exclude the possibility that it is related to *erbB*. However, the MNNG–HOS transforming gene failed to hybridize to probes prepared from the *erbB* portion of AEV (the 2.5-kb *Pvu*II–*Pvu*II fragment described in ref. 34) or from part of the human homologue of *erbB* (the 2.5-kb *Hin*dIII–*Eco*RI fragment he-B, described in ref. 35; data not shown). These data demonstrate that the MNNG–HOS transforming gene is not directly homologous to *erbB*. However, the cloned he-B and viral *erbB* DNA sequences only represent parts of the cellular gene that show homology to *erbB* (ref. 35) and we cannot exclude the possibility that the MNNG–HOS transforming gene may be related to other parts of this cellular gene.

Assuming that the MNNG–HOS transforming gene is unrelated to other transforming genes, we suggest that the three-letter abbreviation, *met*, should be used when referring to this gene.

Table 1 Detection of the MNNG–HOS transforming gene in rodent–human hybrid cells

The rodent–human hybrid cells have been described previously and the presence of particular human chromosomes was determined by chromosomal and isoenzyme analyses[28–31]. The presence of the transforming gene in each hybrid cell line was determined by Southern analysis[17] as described in Fig. 4 legend. The black squares indicate the presence of a particular human chromosome. Hybrid cell line M44 cl2S5 contains only a 14q^{+} t(8;14) human chromosome[47] and hybrid cell line 52-87-3 cl36 is cl2 sub7 contains only a portion of a human chromosome 7, from 7p11.4 to 7qter (ref. 30).

Discussion

This new transforming gene has been mapped to human chromosome 7 (7p11.4 to 7qter) and by these criteria or by direct hybridization seems to be unrelated to other known oncogenes.

The presence of *met* on chromosome 7 is of interest because several different types of human neoplasia are associated with alterations in chromosome 7. Monosomy of chromosome 7, alone or in combination with other chromosomal abnormalities in the same cell, is one of the nonrandom aberrations seen in most subtypes of acute non-lymphocytic leukaemia[36–38]. Several types of rearrangements involving chromosome 7 have also been detected in cells from individuals with ataxia telangiectasia. These include both translocations [t(7;7) and t(7;p14)] and chromosomal inversions[39]. A more detailed localization of the position of the *met* transforming gene on chromosome 7 by *in situ* hybridization may allow a better assessment of the possible involvement of this transforming gene in specific disorders.

The activation of a non-*ras* transforming gene in MNNG–HOS cells is at variance with the observations that most of the transforming genes activated in chemically transformed rodent cells are members of the *ras* family of oncogenes[1–7], and that activated *ras* genes are detected in a variety of human neoplasias, such as lung and colon tumours[40–42], which are believed, at least in part, to result from exposure to environmental carcinogens. Because we have been able to examine only a limited number of human cell lines, it is not yet possible to determine whether the activation of non-*ras* transforming genes is a consistent feature of human cells that are transformed *in vitro* by chemical carcinogens or whether the HOS cell line possesses a unique predisposition to activation of the *met* transforming gene. Some of the transforming genes detected in chemically transformed rodent cells were, however, also unrelated to *ras*. These include genes from DMBA-induced transplantable mammary tumours[43] and mineral oil induced B- and T-cell neoplasms[44].

No detectable rearrangements were observed in the restriction map comparison of the *met* gene in genomic DNA of MNNG–HOS with other human DNA samples. Activation of the transforming gene might therefore involve more subtle changes in the DNA such as the activation of the human *ras*$^{\mathrm{H}}$ gene in the EJ and T24 bladder carcinoma cell lines which involves a single G→T point mutation[45–47]. It is conceivable that a point mutation is also involved in the activation of the MNNG–HOS transforming gene. Alternatively, there may be small insertions, deletions or rearrangements that were not detected in these analyses. As DNA, RNA and proteins can be easily prepared from MNNG–

HOS cells and as the chemistry of the interaction of simple methylating carcinogens such as MNNG is particularly well defined[48], a comparison of the *met* gene from MNNG–HOS cells with the parental HOS cell gene may provide a model system with which to study the mechanisms of transformation of human cells by this carcinogen.

In at least one *N*-nitroso-*N*-methylurea (NMU) induced rat mammary tumour, activation of the ras^{H} transforming gene involves a simple G→A point mutation[3]. Notably, this is precisely the mutation that NMU would be predicted to induce if it reacted directly with the transforming gene. It will be interesting to see whether the precise method of activation of this transforming gene and of other transforming genes detected in chemically transformed cells also reflects the particular chemicals used to induce transformation. Further characterization of the *met* transforming gene and its comparison with the non-transforming allele may provide an interesting insight into one of the ways in which chemical carcinogens can activate proto-oncogenes in human cells.

We thank Dr M. Wigler for the gift of the ras^{N} clone, Drs C. Der, A. Diamond, G. M. Cooper and M.-A. Lane for providing the *Blym, sis, myb, src, erb* and *rel* clones, Dr B. Vennstrom for the human *erbB* clone, Dr Barbara Knowles for the 53-87-3 c136 is c12 sub7 cell lines, Dr David Patterson for 706B6-40 c117 DNA, and Debbie Dugan and Josephine Romano for technical assistance. This work was in part supported by the NCI, DHHS, under contract N01-C0-23909 to G.V.W. and NIH grants CA16685, CA21124 and HD17561 to K.H. and C.M.C.

Sequence requirements for nuclear location of simian virus 40 large-T antigen

Daniel Kalderon, William D. Richardson, Alexander F. Markham* & Alan E. Smith

Biochemistry Division, National Institute for Medical Research, Mill Hill, London NW7 1AA, UK
*ICI Pharmaceuticals Division, Alderley Park, Macclesfield, Cheshire SK10 4TG, UK

A point mutation in the simian virus 40 large-T gene, which was generated by mixed oligonucleotide mutagenesis and resulted in the conversion of Lys 128 to Thr, produced a large-T antigen that was detected in the cytoplasm but not the nucleus of cells. Deletions within the surrounding sequence Lys-^{128}Lys-Lys-Arg-Lys-Val-Glu also produce cytoplasmic large-T and define a region of the protein involved in nuclear location.

THE large-T antigen of simian virus 40 (SV40), molecular weight M_r 94,000, is sufficient to transform established and non-established rodent cells *in vitro* and to induce tumours in newborn hamsters[1]. It is also required for the productive infection of simian cells by SV40[2].

Large-T is a predominantly nuclear protein[3] but is also found in a modified form in the plasma membrane[4,5]. During a productive infection the nuclear form of large-T regulates the level of viral gene expression and stimulates viral DNA replication through an interaction with the viral origin of DNA replication[6–8]. To investigate whether DNA binding by large-T is also involved in transformation we have introduced mutations[9] into a region coding for a putative DNA binding domain of the protein[6,10–13]. Within this domain is a striking tract of five basic amino acids (^{127}Lys-Lys-Lys-Arg-Lys^{131}) just downstream from a cluster of serine and threonine phosphorylation sites[14]. As the sense of the codons for lysine is unaffected by the action of the commonly used mutagen, sodium bisulphite, to mutate this region we devised a modification of oligonucleotide-directed mutagenesis[15,16] that allows the introduction of several defined point mutations in a single experiment.

The large-T protein encoded by one of the mutants generated in this manner contains a threonine residue in place of Lys 128. This mutant large-T, although able to transform Rat-1 cells with wild-type efficiency as measured by focus formation in high serum, accumulates in the cytoplasm rather than the nucleus of

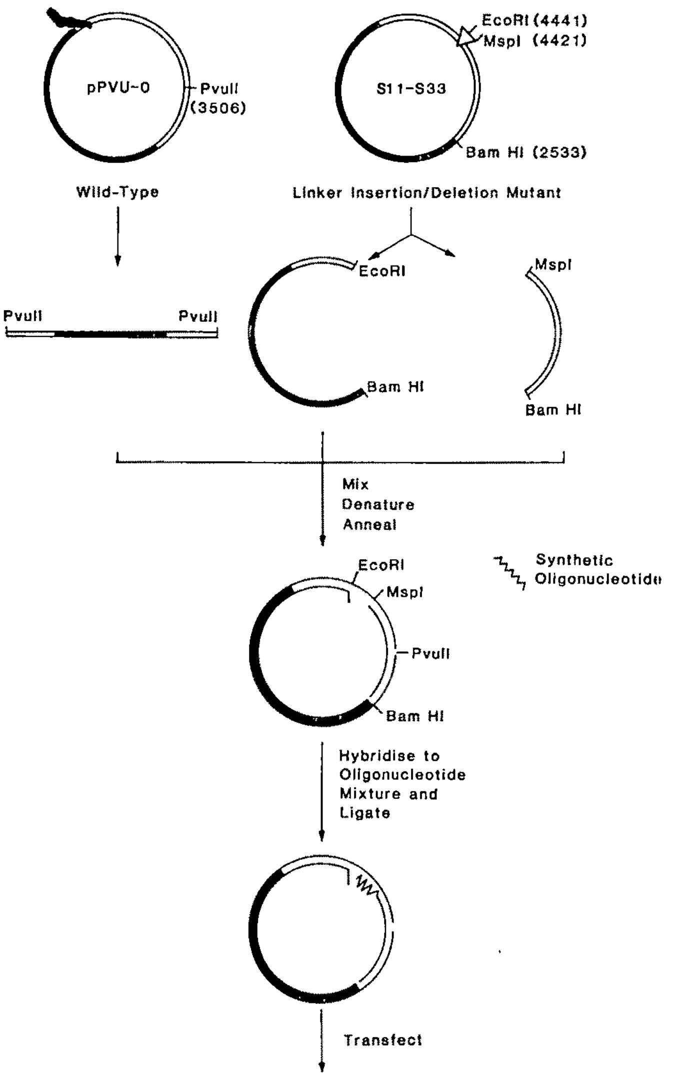

Fig. 1 Mixed oligonucleotide mutagenesis. Plasmid pPVU-0 (ref. 23) contains the wild-type SV40 early region from *Bam*HI (2,533) to *Pvu*II (270) between the *Bam*HI (375) and *Pvu*II (4,676) sites of pBR328 (ref. 37) but with a deletion of 3 base-pairs at the junction of *Pvu*II sites, thus destroying the enzyme recognition site at this point. In the figure, plasmid DNA sequences are shaded whereas the SV40-derived sequences are not. S11-S33 (ref. 9) is a derivative of pPVU-0 that contains a 10 bp *Eco*RI linker (CGGAATTCCG) spanning a deletion between SV40 nucleotides 4441 and 4421. An *Msp*I site is created at the junction of linker and SV40 nucleotide sequences around position 4421. *Msp*I–*Bam*HI and *Bam*HI–*Eco*RI restriction fragments from S11-S33 were purified by agarose gel electrophoresis followed by phenol extraction[9] and were mixed in equimolar proportions with pPVU-0 DNA linearized at its unique *Pvu*II site. After denaturation with alkali and subsequent renaturation[23] about 10–20% of the products migrated as form II (open duplex circles) during agarose gel electrophoresis and were presumed to be circular heteroduplexes of the form shown above. The hybridization products (2.5 μg DNA) were dissolved, after ethanol precipitation in 10 μl of ligation buffer (50 mM Tris-HCl *p*H 8.0, 7.5 mM $MgCl_2$, 1 mM ATP, 10 mM dithiothreitol (DTT) and 0.02% gelatin) and to this was added 2.5 μg of the oligonucleotide mixture (synthesized as in ref. 38) and phosphorylated by T4 polynucleotide kinase, also in 10 μl of ligation buffer. The components were mixed initially at 60 °C, the temperature was then gradually reduced to 0 °C over a 6 h period, after which additional dithiothreitol (to 5 mM) and T4 DNA ligase (6 units) were added. After 1 h at 0 °C, ligation was continued for 4 h at 15 °C. Some of the ligated material was then used directly for transfection. Alternatively, after phenol extraction and ethanol precipitation aliquots were treated with S_1 nuclease (50 units per 10 μl/0.4 μg DNA for 20 min at 37 °C) before neutralization and transfection. S_1 nuclease treatment reduced the number of transfectants about 10-fold. Parallel experiments showed that significant cleavage of nicked circular plasmid DNA did not occur at the S_1 nuclease concentration used.

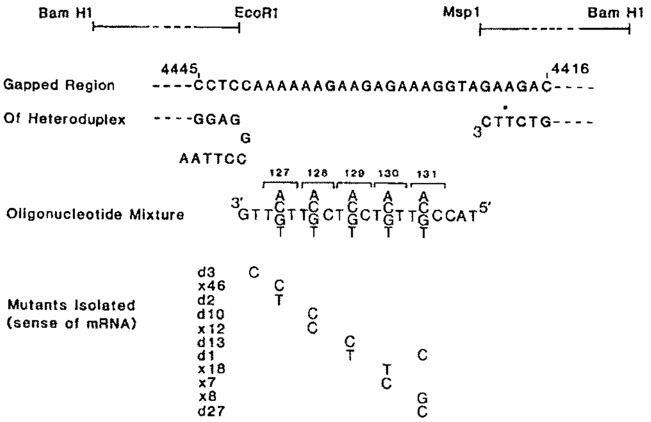

Fig. 2 Mutants obtained using mixed oligonucleotide mutagenesis. The composition of the synthetic oligonucleotide mixture is shown above together with the single-stranded region of the gapped heteroduplex, formed as in Fig. 1, to which the oligonucleotides were hybridized. Note that after hybridization the synthetic oligonucleotides are exactly apposed at their 5' ends to the double-stranded region of the heteroduplex and can therefore be ligated directly into the heteroduplex. The nucleotide sequence alterations in mutant plamids recoverd from the procedure described in Fig. 1 are shown. The inferred alterations to the amino acid sequence of large-T are presented in Table 1. The mutation found in plasmid d3 should not theoretically have been introduced by the oligonucleotide mixture used. It was not studied further because it does not alter the amino acid sequence of large-T.

the transformed cells. The phenotypes of other mutants with lesions in the same area help to define a region around Lys 128 which is required for the nuclear localization of large-T.

Mixed oligonucleotide mutagenesis

Oligonucleotide-directed mutagenesis is currently the method of choice for the introduction of single, precisely defined mutations. However, this method is not generally used for the creation of large families of point mutants because of the labour or expense involved in obtaining a large number of individual synthetic oligonucleotides. In the procedure described here a mixture of oligonucleotides synthesized on a single resin was used as the mutagen.

The mixture of oligonucleotides, each of 20 residues, was synthesized by including an equimolar mixture of all four nucleotides at five selected positions along its length (Fig. 2). The degenerate positions correspond to the second nucleotides in the codons for the basic sequence ^{127}Lys-Lys-Lys-Arg-Lys^{131}, thereby potentially allowing the conversion of each of these residues to any of three different amino acid residues. Thus the oligonucleotide mixture contained 4^5 components, one of which was an exact copy of the wild-type SV40 large-T coding sequence in this region and 15 of which contained a single base change. The oligonucleotide mixture was incorporated into plasmid DNA bearing a cloned wild-type large-T gene by direct ligation into a gapped heteroduplex, formed between wild-type plasmid DNA and two restriction fragments of a linker insertion/deletion mutant derivative of the plasmid (Fig. 1).

After transfection, colony hybridization[17] using a 19-nucleotide long probe of sequence corresponding to the wild-type gene in this region (4,423–4,441:ACCTTTCTCTTCTTTTTTG) was used to detect plasmids bearing mutations within this sequence. Washing filters at increasing temperatures[18] following hybridization at room temperature clearly distinguished between wild-type plasmids in which hybrids were stable up to about 55 °C (in 6 × SSC) and others which showed no detectable hybridization beyond about 45 °C. Although this latter class could itself be resolved into two distinct categories because of differences in the stability of hybridization to the oligonucleotide probe, plasmid DNA was isolated from all poorly hybridizing colonies and examined by restriction enzyme mapping. All plasmids for which hybrids were not stable above ~37 °C, contained large

Transformation assays: Plasmid DNA (10 µg or 1 µg + 9 µg salmon sperm DNA) was transfected into semi-confluent Rat-1 cells by the calcium phosphate method[20]. Cells were grown in Dulbecco's modified Eagle's medium supplemented with 10% fetal calf serum. Dense foci were visible after about 14 days post-transfection and were counted 3–9 days after their first apperance. The numbers above represent the mean of duplicate assays expressed as a percentage of the number of foci induced by the wild-type plasmid, pPVU-0, in the same experiment. The numbers of foci induced by pPVU-0 in these experiments were as follows: Experiment (1) 1,220; (2) 1,150; (3) 446; (4) 500; (5) 464; (6) 694; (7) 634. (A) 170; (B) 94; (C) 50; (D) 76; (E) 62. The deletion mutants RL6 and S5-S32 (ref. 9) which encode a wild-type small-t but severely truncated large-T proteins of 175 and 142 amino acids, respectively, failed to induce any foci in these assays.

Replication assays: Plasmid DNA and viral replication assays were performed as described elsewhere[9]. (–) Indicates that no DNA was detectable in an experiment that would detect 0.1% of wild-type DNA accumulation or that no plaques were detectable within 4 weeks (wild-type plaques are normally visible by 10 days); (+) indicates behaviour indistinguishable from wild-type and (D) (defective) behaviour intermediate between these extremes.

Subcellular localization: Cells derived from transformed foci of Rat-1 cells were grown on glass coverslips, fixed in 4% formaldehyde in phosphate-buffered saline (20 min at room temperature), permeabilized with 1% Nonidet P40 (5 min at room temperature) and incubated with hamster anti-tumour serum followed by fluorescein isothiocyanate-labelled rabbit anti-hamster antibody (Nordic). d10 and X12 transformed cells were also examined using monoclonal antibody PAb423 (ref. 21), followed by rhodamine isothiocyanate-conjugated rabbit anti-mouse antibody. Controls using normal Rat-1 cells and normal hamster serum were included. Normal Rat-1 cells were also generally still present in the population of cells derived from dense foci and thus acted as internal controls for non-specific staining. Immunofluorescence was scored as nuclear, cytoplasmic or mixed. Mixed indicates that three different patterns of staining could be seen in individual cells within a population of transformed cells. Some cells were stained only in the nucleus, others only in the cytoplasm and the rest in both compartments. The most extreme example of this phenotype is d1. Similar localization patterns were seen by staining with the large-T specific monoclonal antibody PAb423 following manual microinjection of each of the mutant plasmids into Vero cells.

* Plaques visible 3 days later than wild-type. † Less than 10% of wild-type DNA accumulation. ‡ Plaques visible 6 days later than wild-type.

deletions (about 2 kb) that included the target for mutagenesis. In contrast, all plasmids for which hybrids were stable to between 40 °C and 45 °C were of wild-type size, indicating the presence of point mutations within the target area. This was confirmed by determining the DNA sequence in this region of all plasmids which formed hybrids of intermediate stability, using the oligonucleotide primed dideoxy procedure applied to double-stranded DNA[19].

Nine of the eleven plasmids sequenced in this way were found to have single point mutations of the wild-type sequence at positions corresponding to the degeneracies in the oligonucleotide mixture (Fig. 2). One mutant plasmid (d1) contained two such alterations and another contained an A to C transversion at a position that should have been invariant (and wild-type) in the oligonucleotide mixture. Two independent isolates of one mutant plasmid (X12; d10) were recovered. In a subsequent experiment using the same oligonucleotide mixture, three further single point mutants were isolated (W. H. Colledge, personal communication). Thus, 12 of the 15 possible point mutants have been obtained. Mutants were recovered corresponding to each of the degenerate positions in the oligonucleotide mixture and examples of each kind of mutagenic change (A → C, G, T) were found. The overall efficiency of production of point mutants was enhanced from 0.7% to 3% by the inclusion of an S_1 nuclease digestion step immediately before transfection, designed to linearize those gapped heteroduplexes to which no oligonucleotide had hybridized. The ease with which large numbers of plasmids can be reliably screened for the presence of point mutations by hybridization to an oligonucleotide of wild-type sequence compensates for the relatively low rate at which mutant plasmids are produced. The genotype of the mutants recovered demonstrates that the mutagenic procedure selects for the incorporation of synthetic oligonucleotides containing single deviations from the wild-type sequence, from a large excess of oligonucleotides with multiple alterations. The principle of mixed oligonucleotide mutagenesis should be applicable to all methods of conventional oligonucleotide-directed mutagenesis currently in use[16].

Transforming activity

The transforming potential of mutant plasmids was assayed by measuring the induction of dense foci on a monolayer of Rat-1 cells following calcium phosphate transfection[20]. The formation of dense foci was large-T dependent, as shown by the failure of deletion mutants that encode a wild-type small-t but severely truncated large-T proteins, to produce dense foci (Table 1). However, all point mutants examined showed a transforming activity similar to wild-type. Although slight differences in specific transforming activity were observed, the latent period before foci became visible was never significantly different from wild-type (13–14 days).

Subcellular localization

Individual foci of transformed Rat-1 cells were picked, the cell population expanded and the subcellular location of large-T assessed by indirect immunofluorescence of permeabilized fixed cells using serum from hamsters bearing SV40-induced tumours as the first antibody.

Rat-1 cells transformed by wild-type large-T, encoded by the plasmid pPVU-0, exhibited a typical nuclear staining with no detectable nucleolar or cytoplasmic staining (Fig. 3*a*). A strikingly different staining pattern was seen for cells transformed by the point mutants, d10 and X12, both of which encode a threonine residue in place of Lys 128 (Fig. 3*c*). The nuclei appear dark against a bright cytoplasmic background. An identical pattern was seen using a monoclonal antibody (PAb423; ref. 21) directed to the carboxy-terminal region of large-T as first

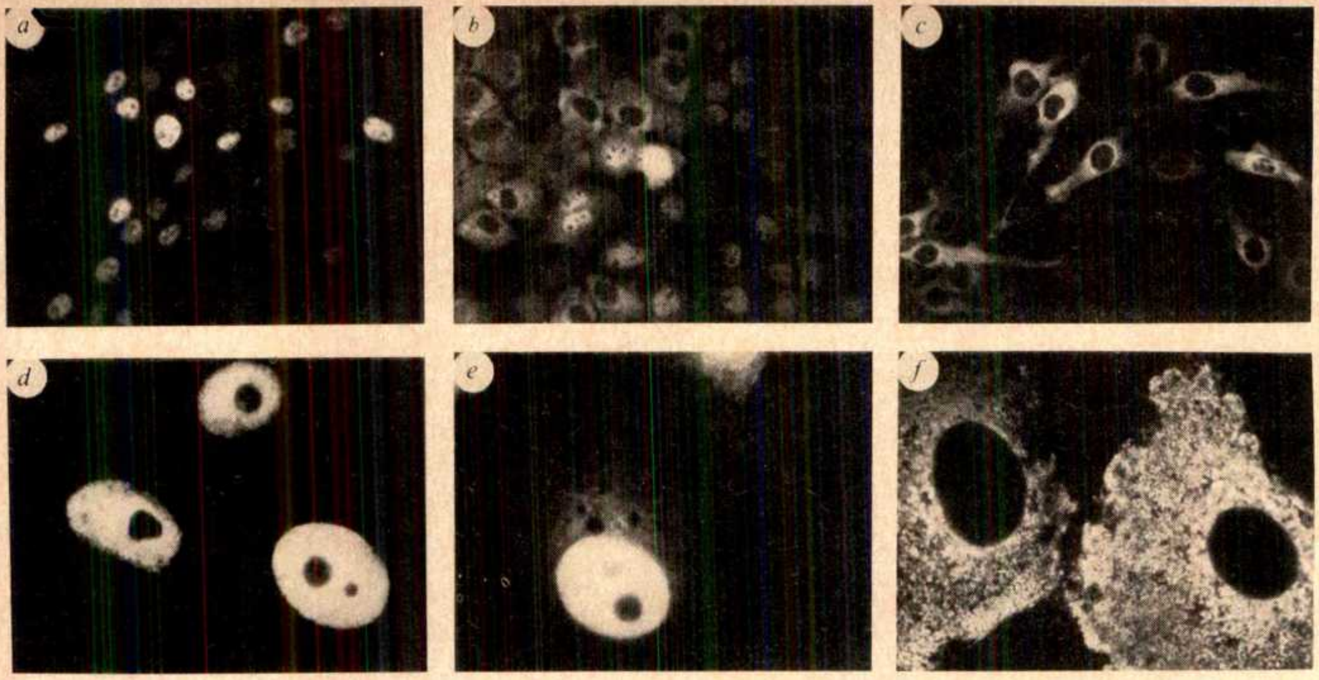

Fig. 3 Nuclear accumulation of large-T in transformed Rat-1 cells and in Vero cells is abolished by alteration of Lys 128 to Thr and impaired by mutation of the surrounding basic amino acid residues. Individual dense foci of Rat-1 cells transformed by wild-type pPVU-0 (panel *a*), the double point mutant d1 (Lys 129→Met, Lys 131→Thr) (panel *b*) and the point mutant d10 (Lys 128→Thr) (panel *c*) were picked and expanded. Cells transformed by d1 were then cloned successively by passage through soft agar and by dilution. Cell lines were fixed and stained by indirect immunofluorescence as described in the legend for Table 1, using hamster anti-tumour serum as the first antibody. The location of large-T in Vero cells was examined by the same indirect immunofluorescence procedure using the monoclonal PAb423 as first antibody, 18 hr after manual microinjection[22] of about 200 copies of plasmid DNA into the nucleus of confluent cells growing on glass coverslips. The plasmids injected were wild-type pPVU-0 (panel *d*), d1 (panel *e*) and d10 (panel *f*). The fields shown in *d–f* are of confluent monolayers and include some cells that have not been microinjected and show no immunofluorescent staining.

antibody. This antibody, unlike anti-tumour serum, does not recognize SV40 small-t antigen which should be expressed in wild-type form by all mutant plasmids used in this study. The same cytoplasmic staining pattern was seen in Rat-1 cells transformed by d10 that were isolated as colonies growing in soft agar.

The exclusion of large-T from the nuclei of transformed Rat-1 cells consequent to mutation of Lys 128 is not observed for similar mutation of individual adjacent amino acid residues that form part of the five residue basic tract ([127]Lys-Lys-Lys-Arg-Lys[131]). Cells transformed by each of these mutants exhibit predominantly nuclear staining. In some cases (d2, X8, X46), the subcellular distribution of large-T appears indistinguishable from that of the wild-type protein. In other cases (X7, X18, d13, d27), a slight defect in nuclear accumulation of large-T is manifest by the presence of some cytoplasmic, in addition to nuclear, staining in the majority of cells derived from an individual focus. Furthermore, a minority of cells from the same focus show predominantly cytoplasmic staining.

The heterogeneous staining pattern (Fig. 3*b*) is even more obvious for the double mutant, d1 (Lys 129→Met, Lys 131→Thr). To date, the subcellular distribution of d1 large-T has been examined in 16 foci, derived from two independent transformation assays. In only one of these was a homogeneous staining pattern observed, with the mutant large-T apparently confined to the cytoplasm of the transformed cells. In all other cases, nuclear staining exceeded cytoplasmic staining in the majority of cells (60–95%); some cells clearly exhibited both nuclear and cytoplasmic staining, whereas in others large-T was apparently either wholly cytoplasmic or wholly nuclear. Cells derived from three of these foci were cloned further either by limiting dilution or by passage through soft agar. In each case, the heterogeneous staining pattern was preserved, indicating that clonally derived sibling cells express a large-T antigen that can, at any one time, be present predominantly in either cytoplasmic or nuclear compartments.

The variable distribution of the large-T protein encoded by the mutants d1, d13, d27, X7 and X18 shows that mutations close to Lys 128 can modulate but do not prevent the accumulation of large-T in the nucleus. Although other interpretations are possible, the heterogeneous localization of large-T in cells transformed by these mutants may reflect a deficiency in the rate of nuclear accumulation less extreme than that observed for d10, which allows the visualization of intermediate stages in the nuclear accumulation of large-T, for example following the breakdown of the nuclear envelope at mitosis.

Transient expression

The wild-type plasmid, pPVU-0, and mutant derivatives were manually microinjected into the nucleus of semi-confluent Vero cells[22] and the location of the encoded large-T products assessed by indirect immunofluorescence 18 h post-injection. The staining patterns observed were virtually identical to those seen for transformed cells but were of much greater intensity, presumably due to the large number of gene copies available for transcription. Thus, large-T coded by wild-type pPVU-0 was exclusively nuclear (Fig. 3*d*) and that encoded by d10 was seen only in the cytoplasm (Fig. 3*f*). Both nuclear and cytoplasmic staining was observed for the mutants d1, d13, d27, X7 and X18 (Fig. 3*e*) but the heterogeneity in this staining pattern between individual cells in a population was not as marked as for transformed cell lines.

Replicative activity

As all mutations were introduced into a plasmid, pPVU-0 (ref. 23) that contains the viral origin of DNA replication as well as the entire large-T gene, the ability of the mutant large-T proteins to stimulate the replication of viral origin-bearing episomes in permissive cells could be tested directly by transfection of mutant plasmids into CV-1 cells and quantitation of intracellular plasmid DNA 72 h later[24]. In addition, the mutant large-T coding sequences from these plasmids were reconstructed into viral DNA and the viability of mutant virus tested by plaque assay[25]. The two assays gave similar results (Table 1), indicating that several of the mutants were unable to support viral DNA replication. Many other mutants[9] with lesions either side of those

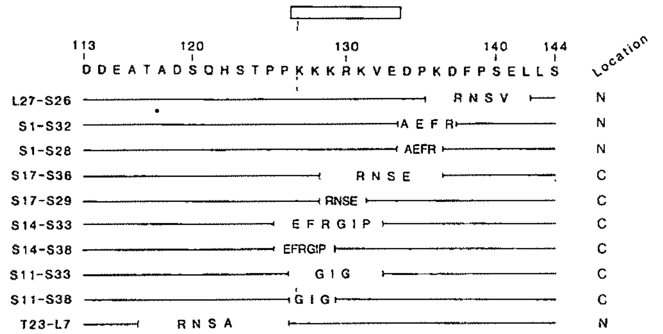

Fig. 4 Amino acid sequence of large-T proteins with deletions in the vicinity of Lys 128. Mutants were constructed from wild-type pPVU-0 containing one or two *Eco*RI linkers CGGAATTCCG at the site of a small deletion[9]. The consequent inferred alterations to the wild-type amino acid sequence are shown. Subcellular localization of mutant large-T antigens in transformed cells was determined as in Table 1 and Fig. 3. (+) (−) indicate the presence or absence, respectively, of nuclear immunofluorescence. Some of the large-T coded by T23-L7 was also detected in the cytoplasm. The box above the amino acid sequence of large-T indicates those residues which cannot be deleted without preventing nuclear localization of the mutants described here. Abbreviations used are: A, alanine; D, aspartic acid; E, glutamic acid; F, phenylalanine; G, glycine; H, histidine; I, isoleucine; K, lysine; L, leucine; N, asparagine; P, proline; Q, glutamine; R, arginine; S, serine; V, valine.

described here also appear to be unable to stimulate viral DNA replication, indicating that this is a common phenotype of mutants from this region.

The viability of mutants altered at Lys 129 and Lys 131, respectively, implies that these (heterogeneously localized) mutant large-T antigens must be able to interact effectively with DNA sequences around the viral origin of replication. Direct measurement of DNA-binding activity *in vitro* by the McKay assay[26] suggests that the non-viable cytoplasmic (d10) and partially cytoplasmic (d1) mutants can also recognize SV40 origin DNA (E. Paucha, D.K. and A.E.S., manuscript in preparation), suggesting that the aberrant localization of these proteins is not related to their ability to interact with SV40 DNA.

Sequences around Lys 128

The data above show that alteration of Lys 128 and, to a lesser extent, the surrounding basic amino acid residues either modulates or abolishes the nuclear accumulation of large-T. The properties of a large number of single, double and triple point mutants with lesions either side of this region between amino acids 106 and 158, by contrast, do not exhibit any impairment in the nuclear accumulation of large-T[9]. The importance of Lys 128 to the localization of large-T is highlighted further by the recent observation of R. G. Lanford and J. S. Butel (personal communication) that the only lesion in the large-T coding sequence of the PARA-cT variant[27], isolated several years ago on the basis of its cytoplasmic phenotype, is the conversion of the codon for Lys 128 to that for Asn.

It is likely, therefore, that Lys 128 forms an essential part of some structural feature of the wild-type large-T protein that allows it either to be transported to or retained within the nucleus. The other possibility that the variant large-T proteins coded by d10 and PARA-cT have acquired an affinity for cytoplasmic components seems improbable, in that a novel specificity of binding is unlikely to be endowed by two different amino acid changes.

The context in which Lys 128 serves to localize large-T to the nucleus has been probed further by examining the properties of a number of insertion/deletion mutants with lesions in the immediate vicinity of Lys 128 (Fig. 4). These were made by standard procedures as part of a more comprehensive mutagenic analysis of large-T[9]. As all of the mutants shown in Fig. 4 were able to transform Rat-1 cells (Table 2), the subcellular distribution of the mutant large-T antigens could be examined in cells derived from transformed foci. In all cases where any part of the basic tract of amino acid residues (127–131) is interrupted, even if this does not include Lys 128, large-T is seen only in the cytoplasm of transformed cells (Fig. 4). However, the normal nuclear accumulation of large-T was not detectably impaired by the alteration of as many as four consecutive amino acid residues distal to Glu 133 and was only marginally affected by changing as many as ten residues proximal to Lys 127. Thus, if there exists a region of primary amino acid sequence around Lys 128 that directs large-T to the nucleus, it probably does not extend beyond Lys 127 or Glu 133. The tolerance of the nuclear large-T mutants L27-S26 and T23-L7 to variation in the length of polypeptide chain separating this sequence from the rest of the molecule perhaps also suggests that the function of Lys 128 is not dependent on a precisely structured three-dimensional configuration within the protein. The cytoplasmic location of several different insertion/deletion mutants supports the argument presented earlier that this phenotype does not result from a novel retention of large-T in the cytoplasm but rather from a defect in transport to or retention within the nucleus.

Table 2 Transforming activity and subcellular localization of large-T proteins with deletions in the vicinity of Lys 128

	Net change in no. of amino acid residues	Nuclear large-T	Transformation of Rat-1 cells	
			No. of foci % wt 10 µg DNA	No. of foci % wt 1 µg DNA
L27-S26	−3	+	81	44
S1-S32	0	+	3, 20, 35*	30
S1-S28	+1	+	30	40
S17-S36	−4	−	66, 50	36
S17-S29	+1	−	38, 53	17
S14-S33	+1	−		
S14-S38	+2	−		
S11-S33	−3	−	72	75
S11-S38	0	−	110	35
T23-L7	−6	+	21	75

The transforming activity and subcellular locations of the mutant large-T proteins in transformed cells is given. These parameters were assayed as described in Table 1.

* These foci appeared 7, 3 and 6 days later than wild-type, respectively.

All of the cytoplasmic insertion/deletion mutants, like d10, transform Rat-1 cells according to dense focus formation in high serum with an efficiency and latent period similar to wild-type (Table 2).

Transformation by non-nuclear T

SV40 large-T is an unusual transforming protein in that it can transform primary cells as well as established cell lines[28] and gives rise to a gradation of transformed phenotypes[29]. In this study only the ability of large-T to transform an established cell line, Rat-1, in high serum was measured by the criterion of dense focus formation. None of the cytoplasmic large-T deletion or point mutants showed a significant deficiency in transforming activity relative to wild-type in this assay. Preliminary experiments indicate that the point mutant, d10, also transforms Rat-1 cells, by the criterion of colony formation in soft agar at high serum concentration with an efficiency similar to wild-type. However, any implication that large-T need not be nuclear to transform, must be tempered by two considerations. First, although large-T is seen by immunofluorescence only in the cytoplasm of cells transformed by d10 or by any of several deletion mutants, some large-T may nevertheless be present in the nucleus but remain undetected, either because of its very low abundance or because it is in a form that is not accessible to the antibodies used for its detection. Second, it is possible that differences in the transforming activity of nuclear and non-nuclear large-T species may be revealed by more stringent assays. By using such assays, R. G. Lanford and J. S. Butel concluded that the cytoplasmic large-T encoded by the PARA-cT mutant induces a partially transformed phenotype in hamster cells, although it can induce colony formation in semi-solid medium and tumour formation *in vivo*[30]. In view of the notion that the transformation of primary cells involves the combined action of a nucelar immortalizing gene product (such as polyoma virus large-T, adenovirus E1a protein, the *myc* gene product) and a membrane-associated protein[31] (such as the *ras* gene product, polyoma virus middle-T), it might be predicted that a non-nuclear large-T would be unable to immortalize or transform primary cells, whereas the plasma-membrane associated form of large-T[5] may suffice to transform established cell lines. These predictions are being tested using the cytoplasmic mutants described here.

Mechanisms of nuclear localization

The nuclear envelope differs from other cellular membranes in that it allows the free passage of virtually all proteins below a certain size (corresponding to approximately 18,000 M_r) in addition to some larger proteins[32–34]. Thus, for any given protein it is not clear whether nuclear accumulation results from a specific mechanism that either facilitates or drives transport across the envelope or whether the protein is free to diffuse, for instance through nuclear pores and is then retained in the nucleus by virtue of an affinity for elements that are themselves confined to the nucleus. This distinction has not been made for SV40 large-T, though the large size of the monomer may favour a specific transport mechanism.

The accumulation of nucleoplasmin in the nucleus of *Xenopus laevis* oocytes[35] is the only case for which there is good evidence for the involvement of a nuclear transport system. Proteolytic digestion of the native pentameric protein has shown that a 16,000 M_r fragment derived from a single 33,000 M_r monomeric unit is sufficient to allow the nuclear accumulation of partial proteolytic cleavage products as large as 101,000 M_r, and is therefore presumed also to specify the nuclear location of the native protein.

Whatever the mechanism of nuclear accumulation, the evidence presented here heralds the possibility that a very restricted region of the SV40 large-T amino acid sequence around Lys 128 may be sufficient to ensure the nuclear location of this protein. Further experiments are in progress to determine more precisely to what extent this putative signal is independent of the rest of the large-T molecule and whether the signal can act in the context of other proteins that are normally cytoplasmic so as to direct them to the nucleus. The availability of the d10 mutant will be invaluable as a control for such studies. When this manuscript was in preparation, M. N. Hall *et al.* reported that restricted sequences derived from the yeast Mat $\alpha 2$ gene product can direct another protein to the nucleus in yeast[36].

We thank Robert Lanford, Janet Butel and Lynna Hereford for communication of results prior to publication, Ed Harlow for monoclonal antibody PAb423, Roger Morris for the gift of rhodamine-isothiocyanate-conjugated rabbit anti-mouse antibody, Joe Brock for help with illustrations and Lydia Pearson for typing the manuscript.

The boundary of the Solar System

R. Smoluchowski

University of Texas, Austin, Texas 78712, USA

M. Torbett

Carnegie Institution, Department of Terrestrial Magnetism,
Washington DC 20005, USA

The shape of the boundary of the Solar System, defined as the surface within which the gravitational attraction of the Sun, rather than that of the rest of the Galaxy, controls the orbital motion of bodies such as planets and comets, has been determined. Outside of this surface, the dominant factors are the radial tides due to the galactic centre and, especially, the vertical tides caused by the galactic disk. Orbits which are direct with respect to the galactic plane, have a boundary which differs from that for retrograde orbits, both being 10–20% oblate and both larger than the, usually assumed, present Oort cloud. The surface may have been the boundary of the early cloud of comets which was later reduced by the passages of stars and molecular clouds.

Losses of bodies from the Solar System are caused by: sporadic perturbations by passing stars or giant molecular clouds, which occur at a rate of several per 10^6 or 10^9 yr respectively, perturbations by giant planets and the steady gravitational perturbation by the galaxy. The first two kinds of perturbations have been extensively studied[1–4]. We now describe the results of a three-dimensional stability study (inertial coordinates) of a system consisting of a comet and the Sun rotating[5] around the galactic centre [mass $1.3 \times 10^{11}\ M_{\odot}$, distance 8.2 kpc (ref. 6)] and periodically traversing the nearly harmonic field of the galactic mid-plane (GMP)[7]. A two-dimensional model of a greatly simplified version of this problem has been studied previously[5] and a corresponding three-dimensional Hill surface is also known[8]. To get an indication of the extent and structure of the boundary of stability[9] paths of comets were integrated numerically for various initial parameters using Cowell's method and fourth-order Runge–Kutta integration. Near the boundary of stability the orbit of a comet is non-keplerian, its semimajor axis a, average inclination i, eccentricity e and the direction of perihelion $\tilde{\omega}$ are highly variable. Thus, for an initial i, the values of e and a were so chosen as to obtain an orbit which was bound for the age of the Solar System. The value of $\tilde{\omega}$ had essentially no effect on the results.

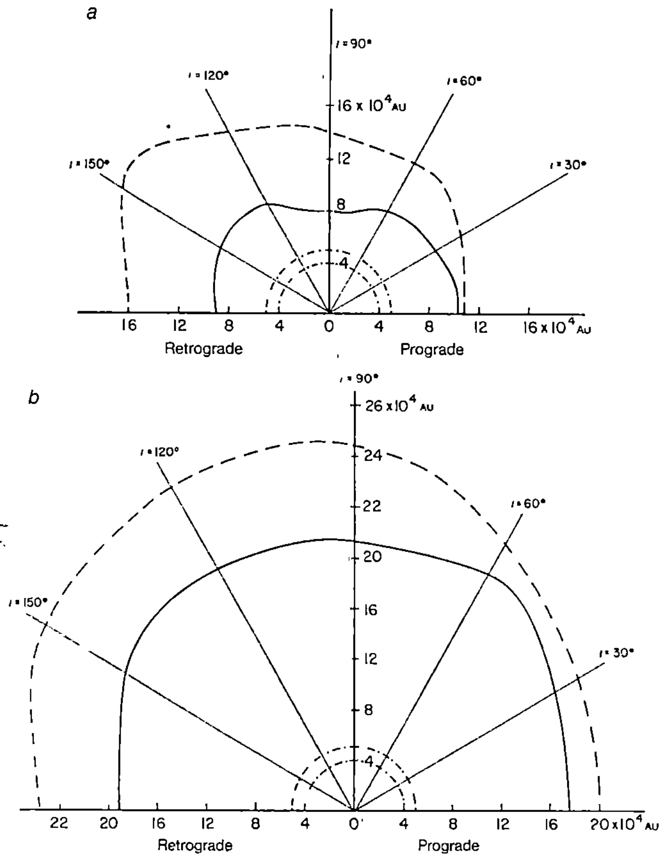

Fig. 1 *a*, Maximum stable semi-major axes of orbits perturbed by the galactic centre alone (dashed line) and by the galactic centre and the mid-plane (solid line). The usually assumed size of the Oort cloud is also indicated (dash-dot line). *b*, Maximum aphelia of orbits perturbed.

The effect of the galactic centre was investigated first and then the influence of the GMP was included. Without such an influence, a cometary orbit is, in general, more stable for high eccentricities and inclinations near 90° as it then senses less of the tidal field of the galactic centre[10] and thus the stability boundary has a proloid shape as shown by dashed lines in Fig. 1. When the effect of the gravitational compression[7] caused by the oscillations of the Sun through the GMP is added, the results indicate a strong destabilization of all orbits especially for i higher than 90°. As shown in Fig. 1, the boundaries of stability then become oblate by 10–20%.

For large a, the periods of orbits are comparable to a substantial fraction of 1.9×10^8 yr, the period of the Sun around the galactic centre or to the shorter period of motion of the Sun across the GMP, so that the directions of the galactic tidal forces change significantly and a resonance can occur between the period of the comet and the other two. The three-dimensional shape of the limits of the stable Solar System, taking both the GC and GMP into account, is obtained by rotating the curves shown in Fig. 1 around the z-axis perpendicular to the plane of the galaxy. This leads to two rather similar co-axial surfaces: the inner one, enclosing the prograde orbits and the outer one, limiting the extent of the retrograde orbits. A rough estimate of the volume of these surfaces suggests that if the density of comets per unit volume were uniform, there would be ~20% more retrograde than prograde comets. The assumption of a uniform density is, however, questionable. Both surfaces have dimensions that are appreciably larger than the commonly assumed radii of the Oort cloud whether based on observation or on other theoretical estimates[1,2,10–13].

Among the stars which penetrate and perturb the Oort cloud those in the mass range of 0.15–0.85 $M_\odot$, have higher velocities than those with masses in the 0.85–1.15 $M_\odot$ range. Taking the mass[14] and velocity distribution into account indicates that the velocity impulse produced by one of the smaller stars is, on average, one-third of that caused by a more massive star. The smaller stars are, however, sufficiently more numerous so that the net perturbations are comparable. The frequency of encounters with the region of stable pro- and retrograde orbits is about 10 per 10^6 yr while for the present Oort cloud it is, depending on the assumed radius, 2–6 per 10^6 yr.

Comets spend most of the time near their aphelia where they are weakly bound and thus the outer regions of both clouds will be severely depleted in spite of continuous redistribution of comets by weak perturbations. It is possible that the early Oort cloud, whatever its origin was comparable in size to the volume of stability here described or, if it were initially smaller, it would have been spread by early perturbations. Later perturbations especially by molecular clouds[3,15,16] decreased the cloud to its present size with a roughly comparable number of prograde and retrograde comets. Such a sequence of events may have an important role in explaining the primordial bombardment of the Solar System. An estimate of the total number of comets in this early cloud and its subsequent changes is beyond the scope of this letter.

Emission of large hydrocarbons from frozen CH_4 by keV proton irradiation

A. E. de Vries*, R. Pedrys†, R. A. Haring*, A. Haring* & F. W. Saris*

Ever since the first description of the synthesis of molecules by impinging protons on ices[1], the possibility of formation of various molecules on cold surfaces by particle radiation has been widely discussed[2–5]. Because fluxes of light ions with energies of ~1 keV AMU^{-1} exist in a wide variety of astrophysical sites[6] there has been a dispute over whether molecules in space are formed by such a process or by gaseous reactions[7]. We have recently studied sputtering of species by bombarding simple frozen gases such as water, carbon monoxide and ammonia with light ions[2]. With these substances, only rather simple molecules were found. However, when bombarding methane, we detected much larger molecules in the sputtered beam—hydrocarbons containing up to at least 13 atoms. We propose, therefore, that bombardment of frozen methane by keV protons may produce large molecules in the Solar system.

Frozen methane at 15 K was bombarded with 6-keV H_3^+ ions and the sputtered flux was analysed by mass spectrometry. The frozen layer had a thickness of ~10 μm (much larger than the range of the projectiles). The ion-beam flux was 50–100 μA cm^{-2}.

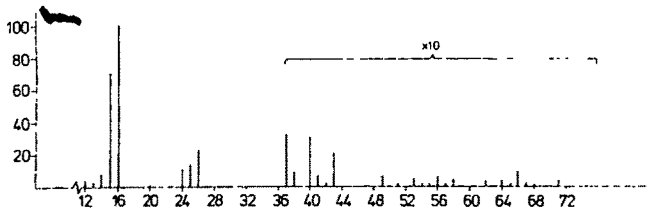

Fig. 1 Mass spectrum of the neutral species sputtered from frozen methane at 15 K by 6-keV H_2^+ ions.

H_2^+ ions were chosen instead of H^+ ions because of achievable ion beam intensity, and on entering the target surface, the H_2^+ ions dissociate at the first collision.

The kinetic energy of the sputtered species was determined by a time-of-flight method[2]. Sputtering of various hydrocarbons was inferred from the spectrum shown in Fig. 1. This gives the signals found in phase with the ion beam modulation, so that continuous background contributions, including those from evaporation, are subtracted.

The signals of sputtered species drastically decrease as the size of molecules increases, and are too low to detect when molecules contain more than five carbon atoms. On the other hand, the total sputtering yield in these experiments is about 1–10, that is, for every incoming ion a few neutral molecules are sputtered. The low fluxes of the larger molecules prohibited time-of-flight measurements, but this was possible for C_2H_2. We found a median energy of 0.063 eV, although 10% of the sputtered C_2H_2 had an energy of >0.28 eV. These energies are far in excess of what can be expected for a volatile substance at 15 K. In addition, the energy distribution is not maxwellian and agrees with that of a collision cascade mechanism[2].

After bombardment, a residue was found which was later warmed up and analysed by pyrolysis mass spectrometry[8]. The resulting spectrum, (Fig. 2) shows masses of up to about 170 indicating that the residue contains molecules with at least 12 carbon atoms. The technique used was the so-called 'open-system flash-pyrolysis mass spectrometry' in which the products from the pyrolysis immediately escape and cannot react with the substrate. Thus synthesis cannot take place but fragmentation clearly does. Note that during the initial warming up of the bombarded layer to room temperature, reactions may have occurred and, therefore, the results from the pyrolysis mass spectrometry only hint that larger molecules may be present in the bombarded sample.

In both the sputtered flux and the residue the largest molecules found were present in concentrations approaching the limit of the sensitivity of our measurements, and thus even larger molecules may have been formed and sputtered by a collisions-cascade mechanism. Obviously some polymerization takes place in the process, producing very large molecules. Polymerization of CH_4 may be caused by electrical discharges, UV light or MeV protons[9], and we conclude from the present measurements that large molecules are also formed by keV ions and infer that a considerable fraction of these is sputtered.

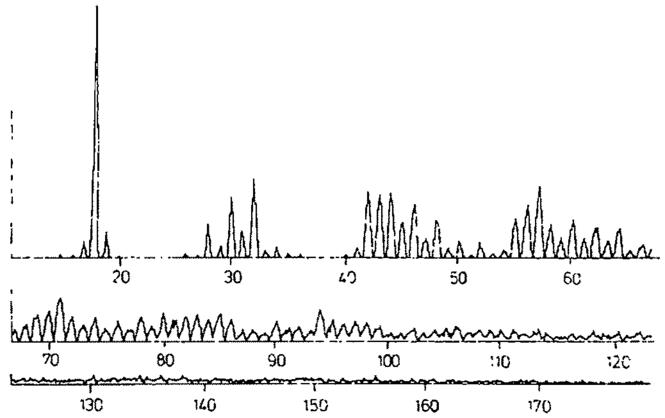

Fig. 2 Pyrolysis mass spectrum of the residue obtained from frozen CD_4 by bombardment with 6-keV H_2^+ ions after warming up to room temperature.

Note that such a process may occur on the most outer planet Pluto and its moon Charon which are covered with methane ice[10,11]. The escape velocity v is given by $v = (2GM/R)^{1/2}$ in which M, R and G are the mass and radius of the planet and G is the gravitation constant, 6.6732×10^{-11} N m^2 kg^{-2}. For Pluto $M = 1.13 \times 10^{22}$ kg and $R = 1{,}800$ km and the escape velocity becomes 917 m s^{-1} (<10% of that of the Earth). The escape energy is then 0.0043 eV AMU^{-1}. For Charon $M = 1.0 \times 10^{21}$ kg and $R = 800$ km. This gives an escape energy of <0.001 eV AMU^{-1}. Therefore, large molecules formed and sputtered from these small planets may turn up in the Solar System. From the above measurements we can infer that the total flux of sputtered molecules is of the same order of magnitude as the incident flux of the solar wind.

Diffuse reflectance pulse radiolysis of opaque samples

F. Wilkinson*, C. J. Willsher*, P. Warwick*, E. J. Land† & F. A. P. Rushton†

* Department of Chemistry, Loughborough University of Technology, Loughborough, Leicestershire LE11 3TU, UK
† Paterson Laboratories, Christie Hospital and Holt Radium Institute, Manchester M20 9BX, UK

Flash photolysis and pulse radiolysis techniques[1] have contributed substantially to our understanding of the harmful and beneficial effects of radiation. The development of extremely short pulsed excitation sources means that time resolution is no longer a serious limitation to the application of these methods[2,3]. However, these methods have previously been restricted to transparent samples because changes in transmission of analysing light were measured following pulsed excitation. Recently[4–6], we have established that photochemical processes within opaque and highly scattering systems can be studied by observing changes in diffusely-reflected analysing light following laser excitation. Many of the most important radiation-induced processes involve non-transparent, heterogeneous systems, for example, most biological systems. We report here the first successful 'diffuse-reflectance pulse radiolysis' experiments in which we demonstrate that time-dependent absorption spectra of short-lived species can now be measured for opaque samples following pulse radiolysis.

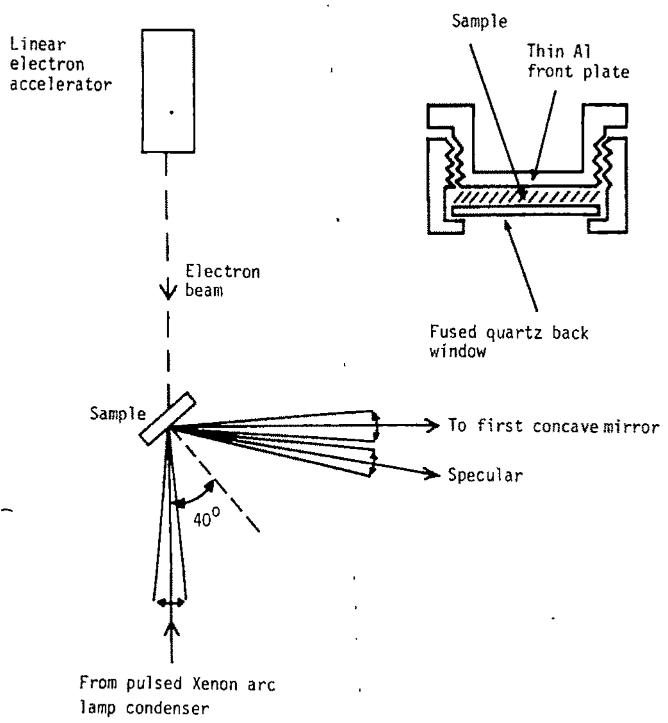

Fig. 1 Schematic diagram of the equipment used for studying diffuse reflectance pulse radiolysis of opaque samples. (Inset shows sample holder in more detail.) Diffusely reflected monitoring light diverging from the sample into a cone of solid angle 0.07 sr is imaged on to the entrance slit of a monochromator (outside the accelerator area at unit magnification) by means of two concave mirrors of 23-cm diameter and 77-cm focal length spaced about 10 m apart.

The pulse radiolysis apparatus has been described previously[7]. Typically 200 ns pulses of 10-MeV electrons were used which delivered doses of up to 100 Gy to the sample through a thin aluminium front plate. Analysing light was obtained from a pulsed xenon arc[8] which was triggered ~750 μs before the excitation pulse fired. This gave a steady reproducible intensity of analysing light which was reflected off the sample through the optically-transparent 'back' face of the irradiation sample holder (see Fig. 1). Collection of specular reflected light with angle of incidence equal to angle of reflection was avoided as far as possible as it contains little transient information. 10-MeV electrons in the excitation pulse are not strongly attenuated on passing through the opaque samples which typically had path lengths of ~1 mm. Thus, 'back' face analysis, which did not require major modification of the pulse radiolysis apparatus designed for normal transmission detection, proved successful (see Fig. 1). This contrasts with the situation when excitation is by pulses of light which are usually substantially attenuated, resulting in a much smaller penetrating depth. Thus, with light excitation, analysis of diffusely-reflected analysing light at the front irradiated surface is essential. The diffusely-reflected light before pulse radiolysis gives a perfect blank in these experiments. A Tektronix 7912 transient digitizer was used to capture the transient information which was then transferred to a minicomputer for analysis. Figure 2 shows a typical set of traces for pulsed radiolysis of microcrystals of benzil analysed at 510 nm. Trace *c* can be corrected for any observed emission, and, by making measurements at different wavelengths, time-dependent absorption spectra of short-lived species produced by pulsed ionizing radiation can be obtained.

The first experiments were performed with opaque samples of organic microcrystals which have already been shown to give transient intermediates in diffuse reflectance laser flash photolysis experiments. Diffuse reflectance pulse radiolysis of benzophenone and benzil give transient absorption spectra which have similar spectra and similar half lives to those obtained by laser flash photolysis[5,6]. Figure 3 shows a comparison of the transient absorption spectra for benzophenone observed from pulse radiolysis and laser photolysis. Phosphorescence decay following pulse radiolysis was also measured and differences were observed between the decay of the transient absorption and the phosphorescence in the case of benzil. This may mean that there is more than one transient absorption, possibly there is some contribution from the negative radical ion of this ketone which would be expected to absorb in the same region as the triplet state.

Several other samples were subjected to the technique and most gave weak transient absorption of <2%. Oxygen was not excluded from any of these samples as the transients observed when microcrystals of benzil and benzophenone are subjected to diffuse reflectance laser flash photolysis are not sensitive to gas phase oxygen. The transient spectrum obtained following pulse radiolysis for naphthalene crystals is shown in Fig. 4*a*.

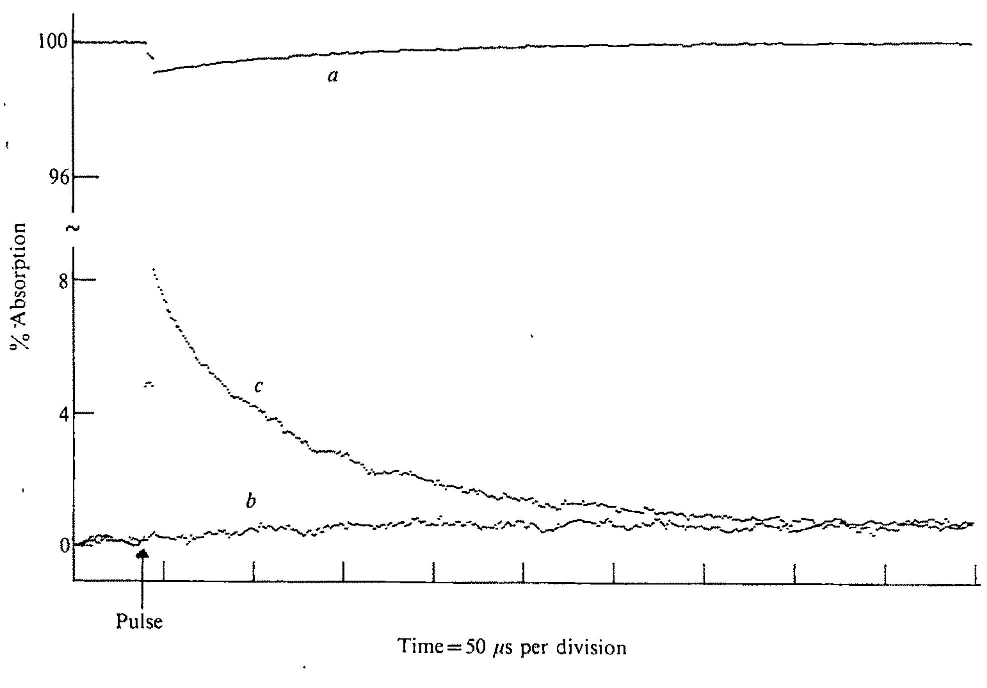

Fig. 2 Transient absorption of microcrystalline benzil, excited by 10-MeV electrons (200 ns pulse), monitored at 510 nm, as a function of time. (Sample thickness = 1 mm, dose ≈ 100 Gy, pulse duration ≈ 200 ns.) *a*, The signal observed following excitation in the absence of analysing light resulting from emission at the analysing wavelength. *b*, The diffusely reflected analysing light in the absence of excitation. *c*, The substantial transient absorption of diffusely reflected light following the pulsed electron excitation.

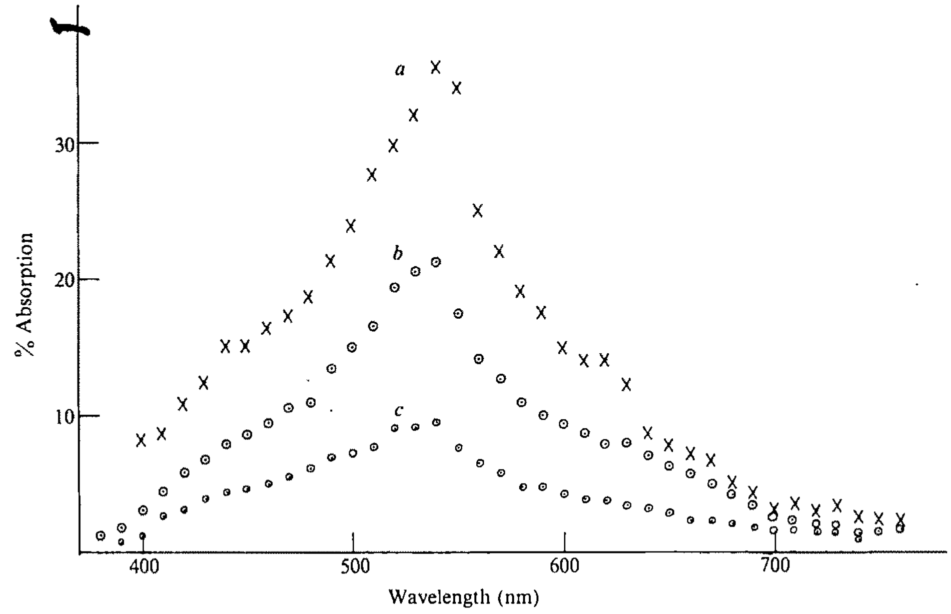

Fig. 3 Excited state absorption spectra of microcrystalline benzophenone. Sample thickness, 1 mm; dose ≈ 100 Gy; pulse duration ≈ 200 ns. *a*, From pulsed laser excitation at 354 nm (ref. 5). *b*, From electron excitation, 3 μs after the end of excitation. *c*, From electron excitation, 13 μs after the end of excitation.

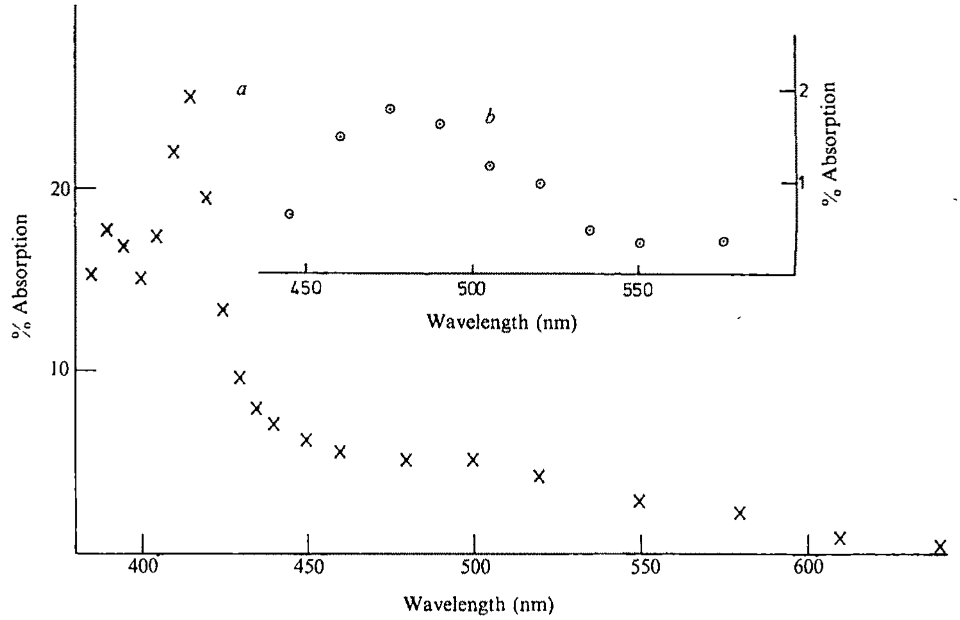

Fig. 4 *a*, Transient absorption spectrum of microcrystalline naphthalene, following pulse radiolysis ($t_{1/2} \approx 20$ μs; sample thickness = 1 mm; dose ≈ 80 Gy; pulse duration ≈ 200 ns). *b*, Transient absorption spectrum of bovine muscle tissue following pulsed radiolysis ($t_{1/2} \approx 20$ μs; sample thickness = 5 mm; dose ≈ 100 Gy; pulse duration ≈ 200 ns).

The absorption spectra in the range 380–440 nm shows strong similarities to the triplet–triplet absorption spectrum of naphthalene obtained in dilute solution using transmission flash photolysis[9]. We tentatively assign the transient absorption in this region to the triplet state of naphthalene. Note that quite a wide distribution of optical absorption path lengths is possible in different samples and that this should be considered in any interpretation of spectra or kinetics.

We stress that pulse radiolysis using diffusely reflected light for analysis extends considerably the range of systems that can be studied by this technique. Diffuse reflectance spectroscopy has been used to probe the effects of radiolysis on, for example, polycrystalline selenites[10], but we believe our work is the first to use diffusely-reflected light to monitor the decay of excited states produced by pulse radiolysis. We feel that this development has most potential for studies of biological systems which are non-transparent. To illustrate this, we have subjected a sample of bovine muscle tissue to this technique and observed the unassigned transient shown in Fig. 4*b*. We consider that our preliminary measurements provide an important step in helping to unravel the mechanism of radiation-induced processes in complicated biological systems and for non-transparent systems in general.

We thank the Cancer Research Campaign for financial support to E.J.L. and F.A.P.R., Loughborough University for support to C.J.W., and Dr J. P. Keene for helpful discussions.

Measurements of hydrogen peroxide in polar ice samples

A. Neftel*, P. Jacob† & D. Klockow†

* Physics Institute, University of Bern, Switzerland
† Department of Chemistry, University of Dortmund, FRG

Hydrogen peroxide, a powerful oxidant, is believed to be a key component in the oxidation of SO_2 to H_2SO_4 in clouds[1]. The first quantitative H_2O_2 measurements in snow, rain, hoarfrost and fog were reported in 1874 (ref. 2), however, systematic investigations of H_2O_2 concentrations in precipitation and hydrometeors began only a few years ago[3,4]. We report here measurements of hydrogen peroxide in polar ice samples. To our knowledge, chemically-reactive species have not been previously analysed in ice core samples. Our measurements show that H_2O_2 is a dominant trace compound present in clouds over remote and clean areas.

The cores from Greenland were drilled as part of the US–Danish–Swiss Greenland Ice Sheet Program. The North Central core, drilled in 1977, and the Dye 3 deep core drilled in 1979–81 were mechanically drilled and are in perfect condition. The Greenland sample series corresponded to a precipitation period of ~1 yr. The locations from which the samples were taken are listed in Table 1 together with their glaciological characteristics.

The analytical system is described in detail elsewhere[5]. Hydrogen peroxide is measured through the chemiluminescence radiation emitted during its reaction with bis-trichlorophenyloxalic ester (TCPO)[6]. Perylene is used as a fluorescing agent. Both the perylene and the TCPO are dissolved in purified acetone. The reaction between the H_2O_2 solution and the TCPO reagent (acetone to water ratio 3:1) takes place in a mixing chamber placed in fromt of a photomultiplier. The emission of the chemiluminescent reaction is linear with H_2O_2 concentration in the range between 0.5 p.p.b. (parts per 10^9) (w/w), detection limit and 30 p.p.m. (parts per 10^6) (w/w).

Because the reaction of hydrogen peroxide with TCPO strongly depends on the *p*H of the solution, the samples were adjusted to a *p*H of 8 using a borate buffer.

Ice cubes (2–5 cm³) were cut in a cold room (−20 °C) with a band saw, so that at least a 1 cm layer was removed from each surface. The cubes were cleaned with a Teflon brush and placed in polyethylene containers. The ice cubes were melted in the containers in a warm water bath (~40 °C). As soon as a whole cube was melted, a sample was taken, mixed with the buffer, and injected into the analytical system. To check whether the handling introduced any noticeable background contamination, ice cubes from a laboratory-grown pure single crystal, purified three times by zone melting, were analysed. The H_2O_2 concentration of such samples were below or close to the detection limit of 0.5 p.p.b.

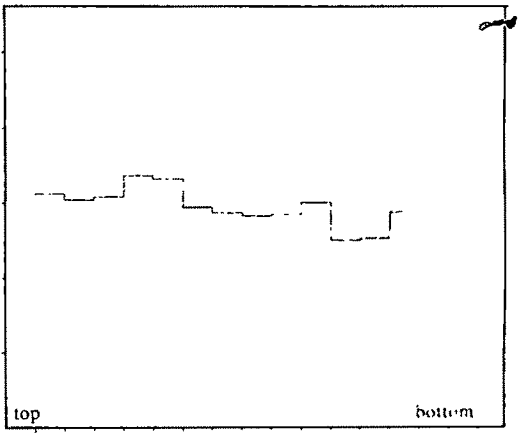

Fig. 1 H_2O_2 concentration along a 26-cm segment from North Central Greenland at a depth of 101 m below the surface. The ice is ~650 yr-old.

Table 1 also shows the measure of mean values of H_2O_2 concentrations with their standard deviation. Figures 1–3 show detailed records from the Dye 3 core and the North Central core.

At Dye 3, melted layers are formed almost every summer[7]. The occurrence of such melted layers may change the H_2O_2 concentration dramatically. In melted layers of the Dye 3 core, concentrations up to 400 p.p.b. H_2O_2 were found (Fig. 2). Figure 2 also shows the distribution of H_2O_2 across a single winter layer of the Dye 3 firn core. A few samples were also analysed from two cores from Antarctica (Byrd and South Pole). (The Byrd core was drilled in 1968–69 and the South Pole core in 1981–82 by the Polar Ice Core Office (PICO).

Because precipitation is stored in the frozen state in ice sheets, chemical trace substances are relatively well preserved and chemical reactions occur extremely slowly. H_2O_2 is produced in the gas phase by the reaction of two HO_2 radicals. The formation of HO_2 radicals in the clean atmosphere starts with the photolysis of O_3 producing O^1 (D), which further reacts with H_2O to form OH radicals[8]. The latter are extremely reactive and several reaction mechanisms, including hydrocarbons and CO as reactants, may lead to the production of HO_2.

A substantial amount of H_2O_2, found in cloud droplets, may have been produced in the liquid phase, due to dissolved OH and HO_2 radicals[9]. It is not known whether H_2O_2 is produced or destroyed at the surface of, or inside, snowflakes, either in clouds or on the ground after deposition.

A small amount of H_2O_2 in the ice could have been produced as a consequence of ionization processes caused by cosmic rays. To estimate an upper limit of this production for the South Pole

Table 1 Locations and glaciological characteristics of samples

Station	Geographical location	Mean annual temperature (°C)	Mean accumulation rate (cm water equiv. yr^{-1})	Measured samples	Depth below surface (m)	Age (yr BP)	Mean H_2O_2 concentration (µg H_2O_2 per kg ice)

* The standard deviation reflects the seasonal variation and melt layer influence (see Figs 2 and 3).

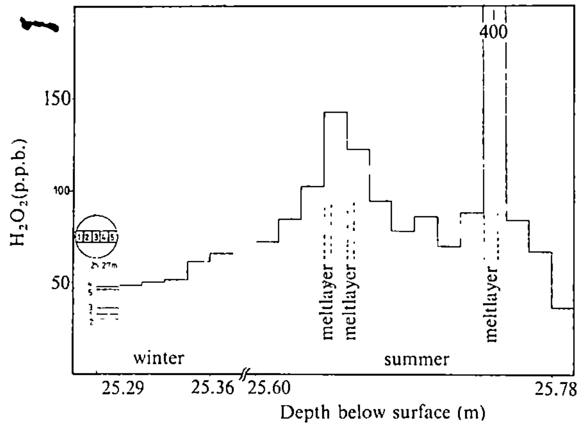

Fig. 2 H_2O_2 concentration in a 30-yr old firn segment from Dye 3 at a depth of 26 m below the surface including melt layers. Summer and winter layers were identified by visual stratigraphy.

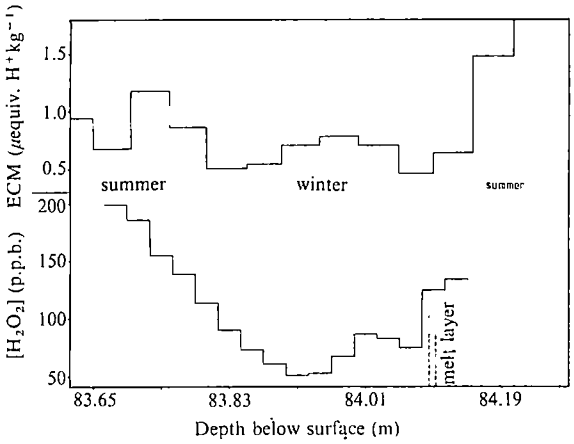

Fig. 3 H_2O_2 concentration and acidity in a 1-yr layer from Dye 3 at a depth of 85 m below the surface, corresponding to an age of 115 yr. Winter and summer layers were identified by the acidity and visual stratigraphy.

core, we assume an ion-pair production of 5×10^3 pairs $g^{-1} s^{-1}$ in the ice[10] and H_2O_2 generation of one molecule per ion pair. Furthermore, we assume that the cosmic ray flux is attenuated exponentially with a damping constant of 0.023 m^{-1} in the first 100 m water equivalent of the ice sheet. With this assumption, 5 p.p.b. H_2O_2 could have been built up in 1,500-yr ice from the South Pole. This crude approximation shows that such a mechanism may be of importance at the South Pole. It has little relevance for Greenland however, because here significantly larger H_2O_2 concentrations have been found in the ice cores.

H_2O_2 is one of the dominant trace compounds in the Greenland cores. In comparison, Table 2 shows mean concentrations of other impurities found in Greenland ice[11] and South Pole firn[12]. The Antarctic samples have a significantly lower H_2O_2 concentration. The annual H_2O_2 deposition rate at Dye 3 would, according to our results, be roughly 30 times higher than at South Pole. This ratio is clearly higher than the one observed for NO_3^- and SO_4^{2-}.

There are three possible causes for the lower H_2O_2 deposition rate at the South Pole:

(1) Transport of H_2O_2 or precursors from mid-latitude sources. Dye 3 is at a much lower latitude than the South Pole, and is meteorologically connected to the continental regions of America and Europe, whereas the whole Antarctic continent is shielded by the circumpolar vortex from lower latitudes.

(2) The stratospheric ozone input to the Southern Hemisphere is lower by a factor of about two[13]. The lower stratospheric–tropospheric air mass exchange in the Southern Hemisphere is also evident from measurements[14,15] of the cosmic ray produced radioisotopes ^7Be and ^{10}Be.

Table 2 Chemical impurities in natural polar ice

Species	Greenland ice sheet* (μmol kg^{-1})	South Pole† (μmol kg^{-1})
Cl^-	0.5	1.25
NO_3^-	1.0	1.44
SO_4^{2-}	0.25	0.75
H^+	1.2	3.37
Na^+	0.4	0.63
K^+, Mg^{2+}, Ca^{2+}	0.1	0.2
NH_4^+	0.3	0.16
H_2O_2‡	3.2	0.5

‡ This paper.

(3) Snow formation and heterogeneous removal mechanisms may differ at South Pole and Dye 3, especially when the lower temperature at the South Pole is taken into account.

The findings, presented in Figs 2 and 3, may be explained by physical and air chemical processes, respectively. High H_2O_2 levels in melt-layers (Fig. 2) indicate that conditions change, if meltwater is present. However, the change of phase of water from the liquid to the solid state decreases the solubility of dissolved impurities by several orders of magnitude[16]. Liquid water in equilibrium with an atmospheric H_2O_2 concentration of 0.5 p.p.b. (v/v), which corresponds to a typical background value[9], would contain 500 p.p.b. (wt/wt) H_2O_2. During the freezing process, H_2O_2 will accumulate in the liquid phase adjacent to the freezing front and will gradually be captured in the ice matrix. Concentrations of H_2O_2 in previously melted layers will, therefore, depend on the mode of refreezing. In addition, any chemical reactions that occur while the water is in the liquid state, as well as increased H_2O_2 deposition during the summer, may also alter H_2O_2 concentrations.

The selected core segment from a depth of 83 m below the surface (Fig. 3) contains only a small melt layer. Nevertheless, the H_2O_2 concentration shows a clear variation, which we interpret as a seasonal variation with high H_2O_2 contents in the summer half year and low contents in the winter half year. The summer and winter layers, respectively, were identified by visual stratigraphy and electrical conductivity measurements (ECM), which give the total acidity in ice[17]. The ECM results show an almost perfect seasonal variation in the Dye 3 core[11]. Indeed, model calculations predict a seasonal variation of the H_2O_2 mixing ratio in the atmosphere for high latitudes, with a maximum in summer[18].

Sublimation and recrystallization smooth out such factors as seasonal variations in $\delta^{18}O$ during the earlier lifetime of the firn from stations with low snow accumulation rates, such as North Central[19]. Thus, we did not expect to see a seasonal variation of the H_2O_2 concentration in the North Central core, and this was confirmed by measurements (Fig. 1).

H_2O_2 is a reactive substance and it is not yet known whether chemical conversions occur in ice. Even if they proceed slowly, they could have affected the H_2O_2 concentration during the hundreds of years since snow formation. Samples from the Dye 3 core from 1,724 m below surface, corresponding to an age of 9,000 yr, gave a mean H_2O_2 concentration of 28.9 p.p.b. Ice samples from the same core with an age of 30,000 yr (ice from the last glaciation) showed H_2O_2 levels at or below the detection limit of 0.5 p.p.b. During the cold periods of the last glaciation, the dust content in the ice was 10–100 times higher than during the Holocene[11]. Perhaps dust was responsible for a catalytic destruction of the H_2O_2 during the snow formation. We cannot decide, however, whether these low concentrations are due to specific atmospheric conditions, or whether they reflect a slow decay of H_2O_2 in the natural ice sheet.

Our measurements show that chemically reactive species, such as H_2O_2, are conserved in polar ice samples. The observed concentrations are not surprising if one takes into account that measurements and model calculations predict similar mixing ratios in ambient air for HNO_3 and H_2O_2 (0.1–1 p.p.b.) and that both trace gases have comparable solubilities in water. If, therefore NO_3^- is found in ice cores, we can also expect H_2O_2 to be present. Although natural ice sheets seem to provide a record of the atmospheric chemical reactor, it is, however, not yet possible to establish any quantitative relationship between the H_2O_2 content of ice and that in the Arctic and Antarctic atmospheres. In the near future, we intend to investigate the effect of sample age on H_2O_2 concentrations to determine more precisely the interhemispheric differences.

We thank H. Oeschger for the opportunity to do this work and his continuing interest. D. Raynaud, R. Delmas and S. Penkett reviewed the manuscript and made valuable suggestions. C. Hammer provided the ECM results from the Dye 3 core segments. P. Warneck gave us much good advice. The development of the analytical system was supported by the Ministry of Science and Research, Nordrhein-Westfalen, FRG.

Age difference between polar ice and the air trapped in its bubbles

J. Schwander & B. Stauffer

Physics Institute, University of Bern, CH-3012 Bern, Switzerland

Air entrapped in bubbles formed in cold ice has essentially the same composition as that of the atmosphere at the time of bubble formation. The analysis of dated ice samples therefore enables the history of atmospheric composition to be investigated.[1–3] The age of the entrapped air is, however, not the same as that of the surrounding ice because air bubbles only become isolated from the atmosphere during the transition from firn to ice. Typically the age of the ice at this transition is between 100 and 3,000 yr, depending mainly on firn temperature and snow accumulation rate. The mean age difference between ice and enclosed air, as well as the age distribution width for a given sample, are especially important for the investigation of the anthropogenic increase of CO_2 and trace gases in the atmosphere over the last centuries, and for the comparison of climatic parameters recorded in the ice with parameters recorded in the bubbles. For Siple Station (Antarctica), this age difference and age distribution width were deduced from the bubble volume measured as a function of depth. The values are 95 yr and 22 yr respectively.

In polar regions, snow is compacted to firn, which is connected to the atmosphere through a system of interconnected pores. The thickness of the firn layer is typically 50–120 m, depending on the temperature and snow accumulation rate. At the depth of the firn–ice transition, the pores are closed-off and individual bubbles are formed. The amount of enclosed air in firn as a function of depth has been measured previously by first removing and discarding the air from open pores, then melting the sample and measuring the amount of gas extracted during melting[4,5]. Two methods have been used to remove the air from the open pores. In the first, the container is evacuated with the ice sample inside; however, this technique carries the risk that some air from closed, but still fragile, bubbles may also be extracted. For the other method, the air in the open pores is displaced by slow immersion of the sample. In this case, however, some of the air from open but dead-ended channels will not be removed.

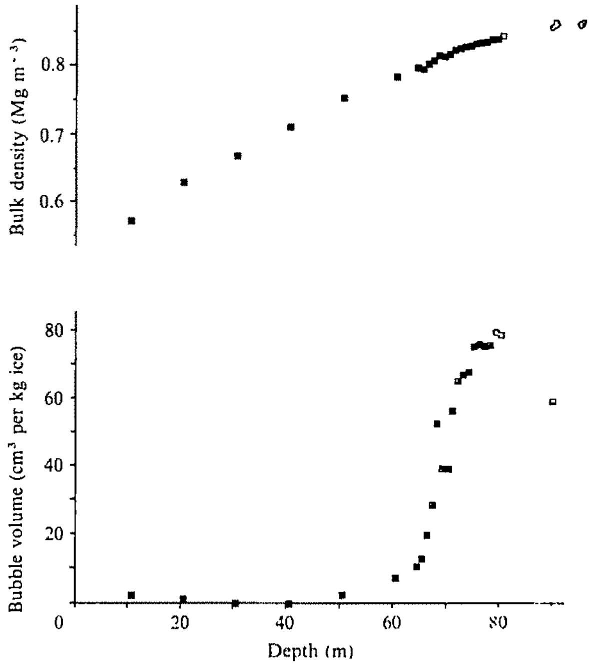

Fig. 1 Bulk density and bubble volume versus depth at Siple Station. Each point represents a 1 m average.

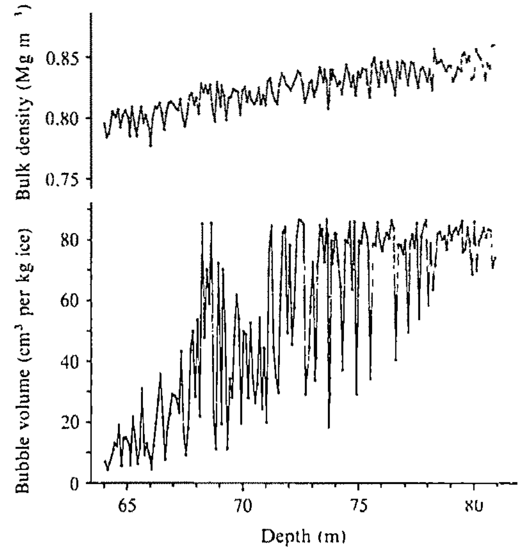

Fig. 2 Detailed bulk density and bubble volume profile of the Siple Station core at the firn–ice transition. Data points are connected by straight lines to illustrate their sequential order

To avoid the problems associated with removing the air first from open pores, we applied the classical method based on the law of Boyle–Mariotte for ideal gases: pressure × volume = constant at constant temperature. Samples are cut to a cylindrical shape of ~35 cm³. The bulk volume is measured with an

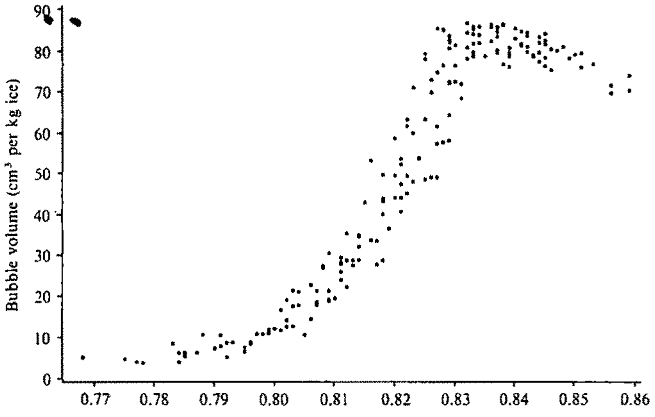

Fig. 3 Bubble volume versus bulk density from all samples between 60 and 81 m depth.

accuracy of 0.1%; the weight is measured with an absolute accuracy of 0.02 g. A calibrated cell containing the firn or ice sample at atmospheric pressure is isolated from the atmosphere and connected to a second, previously-evacuated cell. The pressure decrease, caused by the expansion at constant temperature, allows the volume of the closed bubbles to be calculated. We assumed a pure ice density of 0.919 Mg m^{-3} at −25 °C. There is no danger of disrupting closed but fragile bubbles as the pressure drop is small (5,000–7,000 Pa). The accuracy of the density and bubble volume measurement is ±0.002 Mg m^{-3} and ±2 cm^3 kg^{-1} respectively.

Measurements using this method were made on samples from an ice core drilled in November 1983 at Siple Station (75.92° S; 83.92° W). The main objective for drilling this 192 m core was to determine quantitatively the increase in CO_2 content of the atmosphere since 1800 by analysing air extracted from samples at different depths. The core from Siple Station is especially well suited for this analysis because this location combines a low mean-annual air temperature (−24 °C) with a rather high annual accumulation rate (0.5 Mg m^{-2}). Due to the low temperature, there is only a minimal risk, that the gas composition could be altered by meltwater[6]. A single meltlayer, of 10 mm thickness, was observed in the entire ice core. The high accumulation rate allows a good time resolution and the ice core was dated by counting the seasonal variations of the electrical conductivity of the ice[7]. The age error is <2 yr over the past 200 yr. CO_2 analyses on the Siple ice core will be carried out in the near future. We now focus on measurements which allow the age difference between ice and the enclosed air to be estimated.

All measurements on the ice core were done in a snow trench at South Pole Station[8], where the temperature was very stable (−25 °C). Density and bubble volume of 257 samples from 10 to 91 m depth below the 1982 snow surface were determined. Each point in Fig. 1 represents a 1-m section average, obtained from 10 measurements at 0.1-m intervals. Eighty per cent of the enclosure process takes place between the depths of 64 and 76 m. Only 10% of the final bubble volume is already enclosed above 64 m, and the remaining 10% is trapped below a depth of 76 m. Although at Siple Station (elevation 1,054 m) we expect a mean air content of the ice of 120 cm^3 (STP) kg^{-1} (ref. 5), the measured bubble volume is only 80 cm^3 kg^{-1} at the end of the pore close off (Fig. 1). We deduce a mean bubble pressure at this depth of 140 kPa. The pressure in the bubbles exceeds atmospheric pressure as soon as the bubbles are closed off due to the large local hydrostatic pressure. Detailed results for the depth interval 64–81 m are shown in Fig. 2. The cause of the variations in bubble volume and core density must be seasonal because these variations follow the pattern of the electrical conductivity measurements that distinguish between summer and winter deposits. The summer layers are characterized by low-density and low-bubble volume. The functional dependence between density and bubble volume is shown in Fig. 3 where only measurements between 60 m and 81 m are represented.

To calculate the mean age difference between the ice and the enclosed air, and the age distribution width, we have to assume an age of the air in the open pore volume at the transition zone which is connected to the atmosphere by many meters of permeable firn. ^{39}Ar measurements provide evidence that the air in the open pore volume is well mixed at least down to the beginning of the firn–ice transition[9]. Whether the air in the permeable layers sandwiched between almost impermeable layers is also well mixed with the atmopshere is uncertain. Assuming that the air is well mixed with the atmosphere in all permeable layers, then the mean difference between the age of the ice and the age of the air entrapped in its bubbles is about equal to the age of the ice at a depth where half of the final amount of air is closed off. For Siple Station the mean age difference obtained this way is 95 yr. The age distribution width, defined as the time interval during which the amount of entrapped air rises from 10 to 90% of the final value, is 22 yr. If impermeable layers such as the one from 72.0 to 72.5 m (Fig. 2) have a sealing effect, the mean age difference will be smaller, estimated to be ~90 yr; the age distribution width should also be smaller, although it is difficult to estimate by how much.

Only 10% of the bubble volume is formed at a bulk density of <0.795 Mg m^{-3}, while the final 10% is formed at densities above 0.83 Mg m^{-3}. Results from ice samples from Dye 3 (unpublished data) and North Central, Greenland[10], suggest that these values might be valid for most polar sites. A semi-

Table 1 Measured values for Siple Station, and calculated values for other important sites, of the difference between the age of the ice and the mean age of the air trapped in its bubbles as well as the age distribution width

Site	Location		Mean annual air temperature (°C)	Annual accumulation (m water equivalent)	Width of age distribution (yr)	Difference between mean age of ice and year (yr)
					Measured

empirical formula by Herron *et al.*[11] allows the density and age of the firn to be calculated as a function of depth if mean firn temperature, yearly accumulation rate, and snow density at the surface are known. We calculated the mean age difference between the enclosed air and ice, and the age distribution width using this formula for different stations, assuming that the air is of zero age in all open pores at any depth, and that 80% of the air is enclosed between the densities 0.795 and 0.83 Mg m^{-3}. The results are given in Table 1. The width of the age distribution limits the time resolution for the detection of variations of the past atmospheric composition obtained from ice core analysis.

If the air is well mixed, even in permeable layers sandwiched between impermeable ones, then it should be of different ages in neighbouring seasonal layers. In periods showing an increase in the concentration of an atmospheric component we would expect summer layers to show higher concentrations than winter layers because bubbles in the winter layers close off earlier than those in the summer layers. Measurements of such a seasonal modulation of CO_2 concentration during a period of industrial CO_2 proliferation should provide detailed information on the CO_2 increase and the mixing of the air in the permeable layers at the firn–ice transition.

This work has been supported by the US NSF and by the Swiss NSF. The ice core at Siple Station was drilled by the Polar Ice Coring Office, Nebraska.

Chronology of palaeoclimatic change at the end of the last glaciation

R. B. Stewart & V. E. Neall

Department of Soil Science, Massey University, Palmerston North, New Zealand

Analysis of sediments recorded in a piston core, located east of southern North Island, New Zealand, gives a detailed record of climate change at the end of the last glacial. Accumulation rates[1] of both detrital (quartz) and biological (carbonate and biogenic silica) components of the sediment are much higher during glacial than post-glacial time and they all show a synchronous, rapid decline at 14,700 yr BP. We attribute this to a decline in intensity of the strong glacial westerly winds in the New Zealand region as the polar winds contracted to their present latitudes[2–6]. The greatest rate of quartz accumulation occurs between 16,200 and 14,700 yr BP and is not matched by any change in carbonate or silica accumulation. We believe this reflects accelerated fluvial transport of detritus out of the mountain ranges and consequently increased aeolian dust transport before the decline of the polar westerlies.

Accumulation of greater amounts of quartz in deep-sea sediments during glacial periods than during times of warmer climate has been recognized[7,8] and been attributed to increased wind erosion from arid regions during those cold periods[7–11]. A marked change in global atmospheric circulation at the end of the last glaciation has also been inferred from changes in manganese abundance in east-equatorial Pacific deep-sea sediments[12] and from changes in the microparticle content of polar ice[13,14]. In the New Zealand region, differences in the distribution of quartz between surface sediments and those deposited ~18,000 yr BP have been used to infer that the westerly winds in the south-west Pacific were more intense and extended further north during the last glacial than they do today[6].

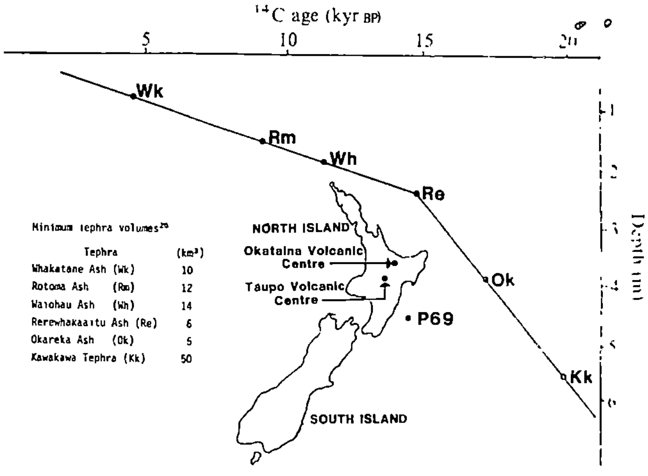

Fig. 1 Depth versus radiocarbon age of tephras in core P69 collected on cruise no 1059, Northland Plateau sediments, 17–31 March 1977 (from R/V *Tangaroa*), located at 40°23′ S, 177°59.8′ E. Mean pre-and post-Rerewhakaaitu Ash sedimentation rates are 594 mm kyr^{-1} and 156 mm kyr^{-1} respectively. Wk, Whakatane Ash (4,640±90 yr BP, NZ 3949A); Rm, Rotoma Ash[37] (9,120 ± 30 yr BP, NZ 1945A) Wh, Waiohau Ash (11,250±200 yr BP, NZ 568A); Re, Rerewhakaaitu Ash (14,700±200 yr BP, NZ 716A); Ok, Okareka Ash (estimated age of ~17,000 yr BP from terrestrial sequences); Kk, Kawakawa Tephra (19,850±310 yr BP, NZ 1056A). NZ numbers are New Zealand radiocarbon numbers. All tephras are from Okataina Volcanic Centre except Kawakawa Tephra, a Taupo Volcanic Centre eruptive.

As part of a wider project examining the accumulation of aerosolic dust in New Zealand we obtained a piston core from 2,195 m depth of hemipelagic sediment from a location 110 km east of southern North Island, New Zealand (Fig. 1). Quartz content in selected size fractions was determined by pyrosulphate fusion and hydrofluorsilicic acid digestion[15], carbonate was determined by a titrimetric method[16] and biogenic silica content by X-ray diffraction[17]. Time control is provided by six identifiable rhyolitic tephras[18,19] erupted from the central North Island during the late Quaternary, five of which have been reliably radiocarbon dated in terrestrial sequences[20] (Fig. 1).

Rerewhakaaitu Ash (14,700 yr BP) occurs in a stratigraphical position marking major changes in sedimentation in the core. The mean sedimentation rate before this age is 594 mm kyr^{-1}, markedly greater than that of the younger sediment at 150 mm kyr^{-1} (Fig. 1). As there is no evidence of major erosion or turbidites in the core, we believe that this change in sedimentation reflects the change in climatic conditions (especially a change in the westerly wind system) at the end of the last glaciation, influencing the supply of terrestrial sediment to the marine environment.

To elucidate the nature of this change in more detail the accumulation of three components of the sediment, one detrital (quartz) and two biological (carbonate and silica) were determined (Fig. 2). Quartz accumulation in both the 62–20 μm (representing loess) and 5–2 μm (representing aerosolic dust)[21] size fractions showed a consistent, abrupt decrease in accumulation at ~14,700 yr BP. Quartz accumulation in both size fractions shows a maximum between ~16,200 and 14,700 yr BP. It is generally recognized that the glacial maximum occurred at about 18,000 yr BP in New Zealand[22] and the period of maximum rate of quartz accumulation in the core clearly postdates this time. We interpret these data as showing that during and after the

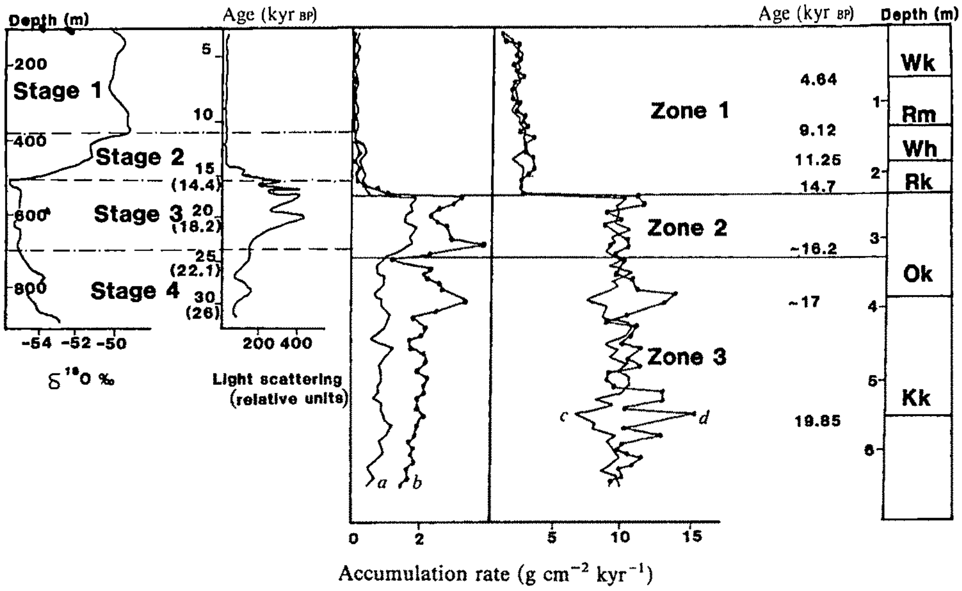

Fig. 2 Accumulation rates of: *a*, 5–2 μm quartz; *b*, 63–20 μm quartz; *c*, biogenic silica; *d*, carbonate. Tephra nomenclature is that described in Fig. 1. Zone 1 represents post-glacial sedimentation, zone 2 the period of accelerated erosion at the end of the last glaciation, and zone 3 the sedimentation during part of the last glaciation itself. The secondary maximum in 63–20-μm sized quartz is in part attributed to volcanic quartz from Okareka Ash, which occurs in this stratigraphical position. The oxygen isotope and microparticle (from light scattering in relative units) distribution curves are from Dome C ice core[14] for comparison.

glacial maximum, a strong westerly wind system existed across the southern North Island. During the period 16,200–14,700 yr BP (zone 2, Fig. 1) we postulate an increase in fluvial activity in the early part of the climatic amelioration following the glacial maximum. This would increase transportation of erosion detritus stored in the mountain ranges during the cold, dry, glacial climate, to form the extensive aggradational surfaces of the lowlands. The continuing strong westerlies would have caused substantial wind erosion from these aggradational surfaces and resulted in increased aeolian transport of detritus to the marine environment east of the southern North Island. At ~14,700 yr BP the contracting westerly wind system passed to the south of the region and the abrupt decrease in wind erosion and transport resulted in a large decrease in the detrital component of sedimentation at this time (zone 1, Fig. 1).

The change in wind regime at 14,700 yr BP is also correlated with palynological evidence from central North Island where forest expansion began after this time[23,24]. The change is also consistent with observations of the Rerewhakaaitu Ash overlying a widespread erosion break in terrestrial tephra sequences of central North Island[23–25] and the cessation of tephric loess accumulation.

This interpretation of the quartz accumulation data is supported by the changes in accumulation of the biological components. These also show an abrupt decrease in accumulation rate at ~14,700 yr BP (Fig. 2), indicating a marked change in the marine biological environment at this time. Biological productivity in the oceans is a function of nutrient content, particularly phosphorus[26,27], of surface waters and nutrient concentration is generally higher in cold polar and sub-polar waters. Upwelling of these nutrient-rich waters is predominantly caused by strong winds[27–31] and so patterns of biological detritus accumulation in the oceans are closely related to global wind patterns[17,27,29]. The abrupt change in accumulation rate in biological components in the core at 14,700 yr BP is thus interpreted as a response to the strong glacial westerly wind system decreasing in intensity and contracting poleward at the end of the last glaciation. As the factors which caused increased accumulation of quartz between the glacial maximum and 14,700 yr BP would have had little effect on biological activity in the marine environment, no change occurred in the glacial accumulation rate of the biological components until the decline of the glacial westerly wind system ~14,700 yr BP.

Our data are consistent with a climatic amelioration beginning at ~16,200 yr BP, corresponding to initiation of a global rise in sea level[32,33] following the glacial maximum. By ~14,700 yr BP the energy balance of the ocean–atmosphere system was such that the glacial circumpolar wind systems began to contract towards their present post-glacial latitudes. Evidence of a change in particle transport at about this time has been found in both Arctic and Antarctic ice cores, concomitant with evidence of a change from cooler to warmer climate shown by oxygen isotope ratios of ice from the same cores[13,14,34]. Comparison with the Dome C ice core[14] shows that our zone 1/2 boundary correlates closely with their isotope stage 2/3 boundary and a similar distribution in microparticle content occurs (Fig. 2). Thus our inferred palaeoclimatic history from core P69 appears to be consistent with evidence from both deep-sea sediments and ice cores, suggesting that these changes were global. Finally, the terrestrial climatic changes reported here for New Zealand are for a maritime environment which may have responded more rapidly to global climatic variation than continentally glaciated areas on which ice sheets persisted into Holocene time[35,36].

This research is part of a wider study into the provenance of quartz in soils and sediments in New Zealand and we thank the New Zealand Department of Scientific and Industrial Research for funding.

Turbulent motions may control phytoplankton photosynthesis in the upper ocean

M. R. Lewis*†, E. P. W. Horne†, J. J. Cullen†, N. S. Oakey‡ & T. Platt†

* Department of Biology, Dalhousie University, Halifax, Nova Scotia, Canada B3H 4J1
† Marine Ecology Laboratory, and ‡ Atlantic Oceanographic Laboratory, Bedford Institute of Oceanography, Dartmouth, Nova Scotia, Canada B2Y 4A2

In their natural environment, algal cells may experience large amplitude variations in incident light on time scales shorter than those associated with the reproductive rate. A major source of variability is due to vertical mixing of water masses: turbulence in the upper mixing layer of the ocean transports algae through a light field that decreases exponentially from the sea surface. Several attempts have been made to discover how the physiological adaptation of algae to fluctuating light[1–9] might affect the magnitude of marine primary production[10–16,17], but it has proved difficult to estimate the vertical mixing rate at sea, and hence the time scales of irradiance variability [18,19]. We recently succeeded, for the first time to our knowledge, in making direct measurement of rates of turbulent kinetic energy (TKE) dissipation, simultaneously with those of photoadaptation properties of natural phytoplankton populations. Dissipation of TKE in these experiments was a strong determinant of algal photosynthetic rate in the upper mixing layer; we conclude that the vertical mixing induced by turbulence to a large degree controls the photosynthetic performance of algae in nature.

The experiment attempted to test hypotheses generated by a recent theoretical analysis of algal photoadaptation in a mixing water column[20], where the significance of photoadaptation was evaluated by considering the time scales at which algal cells would be exposed to changing light intensity. As a first approximation, a simplified bulk view of the turbulent velocity field was taken. It is assumed that the algal cells remain uniformly distributed with depth. Then, any changes in a measurable index of photoadaptation (for example, maximum photosynthetic rate, *in vivo* fluorescence), at a particular depth, can be separated into two terms, one denoting physiological adaptation, and the other changes which result from turbulent fluid motion. As cells are transported in the vertical, irradiance incident on the cells varies. When the rate of photoadaptation is high relative to the rate of turbulence-induced light fluctuation, photoadaptation should produce variations in the photoadaptive property with depth. Conversely, when the rate of photoadaptation is low relative to that of turbulence, photadaptive variations in depth should be smoothed out by turbulence and consequently algal populations throughout the water column should be physiologically homogeneous. The physiological index, for a sample from a particular depth horizon, is an ensemble average of all cells present: it also contains (weighted) information about the recent light history of the cells. For fluid motions sufficiently rapid, samples taken anywhere in the mixing region should have the same average light history and therefore should be indistinguishable with respect to the magnitude of the physiological index. To test these hypotheses,a reliable and independent estimate of the rate of vertical mixing is required.

We therefore designed an experiment where the rate of turbulent mixing was determined simultaneously with the vertical distribution of photoadaptive indices. The experiment was carried out in Bedford Basin, a coastal marine inlet adjacent to the laboratory. Stations were occupied twice a day every 2–3 days for a one-month period during the spring. At each occupation samples were taken from the surface and bottom of a near surface mixing region distinguished from a temperature trace (Guildline SCTD) taken at time of sampling (Fig. 1). Maximum

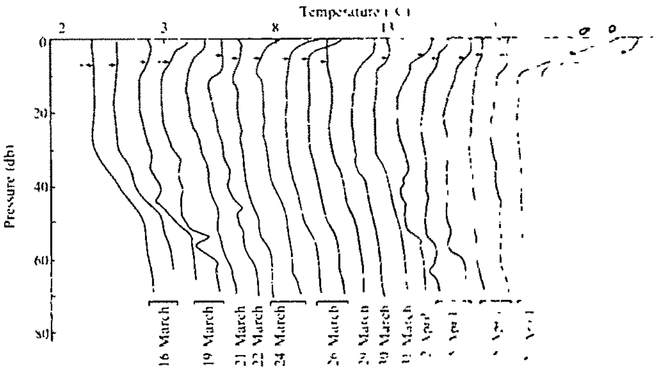

Fig. 1 Profiles of temperature during the study with the dates and sampling depth indicated. Profiles are offset by 1 °C. When two profiles are indicated for a single day, the first is a.m., the second is p.m.

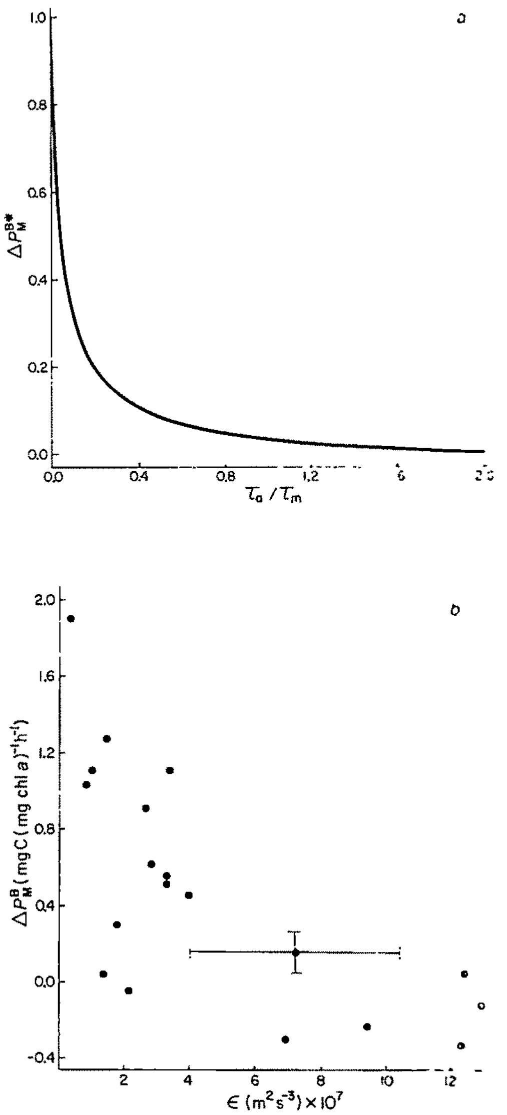

Fig. 2 *a*, Results from analytical solution[20]. ΔP_m^{B*} is the normalized difference between surface samples and those at the base of the mixing region. The irradiance gradient is the same as that in the field study. τ_a/τ_m is the ratio of the photoadaptation time scale to the mixing time scale. *b*, Measured differences between P_m^B at the surface and P_m^B at the base of the mixing region as a function of turbulent energy dissipation rate, ε. Error bars are ±1 s.d.

potential photosynthetic rate normalized to chlorophyll a, P^B_m, was determined by methods described previously[21,22] *In vivo* fluorescence per unit chlorophyll, a photoadaptive index with a rapid response to irradiance changes[23-25], was also measured after a 15-min dark adaptation time. Rates of TKE dissipation, $\varepsilon(m^2\,s^{-3})$, were determined from direct measurements of velocity shear microstructure[26-29] from the recently-developed microscale profiler, Octuprobe[28] according to,

$$\varepsilon = 7.5\nu\overline{\left(\frac{\partial u'}{\partial z}\right)^2} \qquad (2)$$

where $\overline{(\partial u'/\partial z)^2}$ is the averaged variance in turbulent velocity shear and ν is the kinematic viscosity. The numerical constant is a factor for isotropy. Values of ε over the depth interval 2–10 m were averaged over 6 or 7 realizations spanning 25 min. These values of ε were compared with differences between P^B_m and fluorescence parameters over the mixing region.

Results, shown in Fig. 2*b*, were consistent with the expectation of prior[20] theoretical analysis (Fig. 2*a*). At high TKE dissipation rates, little depth variation in P^B_m was observed; on days when energy dissipation rates were low, surface samples showed higher values of P^B_m (Fig. 2*b*). This strong inverse correlation between ΔP^B_m, which measures the physiological homogeneity of plankters over the mixing region, and ε, which is determined from dissipation scale fluctuations in velocity shear, does not result from an inconsistency of scales. The large-scale processes generating TKE may well be of the scale of the mixing region. Variations between days in the irradiance gradient were not significant. Order of magnitude mixing time scales to compare with those in Fig. 2*a* can be estimated from,

$$\tau_m = l^2 K_v^{-1} \approx 4 l^2 \varepsilon^{-1} N^2 \qquad (3)$$

where l is the depth of the mixing layer, K_v is the eddy diffusivity and N is the Brunt–Väisälä frequency[28,30-32]. Algal populations became physiologically more uniform throughout the mixing region as ε became larger. With $\varepsilon = 4\times10^{-7}\,m^2\,s^{-3}$ and with measured values of $l \approx 5$ m, and $N \approx 10^{-2}\,s^{-1}$, the corresponding mixing time scale is ≈ 10 h. This value is consistent with laboratory estimates of the photoadaptation time of P^B_m ($= \tau_a$; Fig. 2*a*) of 6–10 h (refs 9, 20). Some of the observed residual scatter could be due to other environmental factors such as temperature, nutrient supply and grazing (see ref. 19). The relationship in Fig. 2*b* would suggest that the dominant source of variation responsible for the observed difference in physiological performance is turbulence-induced fluctuations in light incident on the algal cell.

Few motile cells were observed; the dominant species was the diatom *Melosira*. Populations of motile cells could potentially resist the vertical displacement induced by turbulence. If the swimming velocity is $\bar{w}$, a 'swimming time scale' can be estimated as $l\bar{w}^{-1}$ and compared with τ_m to determine which vertical motion would dominate. For a typical swimming velocity[33] of the order of $10^{-4}\,m\,s^{-1}$, and the parameter values used here, ε would have to exceed $\approx 10^{-7}\,m^2\,s^{-3}$ for the mixing process to dominate, as it does here (Fig. 2*b*).

In-vivo fluorescence, when normalized to unit chlorophyll concentration, was less at the surface in the afternoon on all days except one—the day of highest measured dissipation. This was also consistent with our hypotheses; the time scale for variation in *in vivo*, chlorophyll-specific fluorescence on exposure to high light ($>100\,W\,m^{-2}$) is ≈ 1 h (refs 23–25), comparable with our highest estimate of $\tau_m \approx 1$h. The sea-surface irradiance (400–700 nm) varied between 100 and 400 $W\,m^{-2}$ at noon. The observation of decreased fluorescence yield for most days at the surface is therefore consistent with a mixing time scale for these days greater that ~ 1 h.

We conclude that turbulent fluid motion in the upper layer of the ocean controls to a large degree the physiological performance of algal cells. Only when energy dissipation rates are high can algal populations in the upper 'mixed' layer be considered physiologically homogeneous. It also appears from these data that the rate of vertical mixing in the upper layer may be inferred from the vertical distributions of appropriate algal physiological indicators.

We thank Mr B. Irwin, Mr P. Dickie, and Mr M. Hodgson for field assistance and Dr K. H. Mann for critical reading of the manuscript. M.R.L. was supported by the Natural Sciences and Engineering Research Council (Canada) and by a Dalhousie University Fellowship.

Nitrate leaching from grassland

J. C. Ryden*, P. R. Ball† & E. A. Garwood*

* The Grassland Research Institute, Hurley, Maidenhead,
Berkshire SL6 5LR, UK
† Grassland Division, DSIR, Private Bag, Palmerston North,
New Zealand

Increased awareness of the economic importance of losses of nitrogen (N) from agricultural land, together with the recognition that nitrate in drinking water is potentially detrimental to human health, have stimulated research on nitrate leaching[1-4]. Various reports[5-7] have suggested that the leaching of nitrate from arable land is the major source of nitrate to water supplies in east and south-east England. In contrast, leaching from grassland is thought to be small[5,8-10]. However, this conclusion has been based largely on studies of leaching below cut swards, which exclude the effect of ruminants (cattle and sheep) on nitrate loss. This effect is likely to be substantial as <20% of the input of N to grassland systems is recovered in products of the ruminant animal[11]. Our study demonstrates that the amount of nitrate leached below a grass sward grazed by cattle was 5.6 times greater than that leached below a comparable cut sward and exceeded the losses normally observed from arable land.

The extent of leaching was assessed by measuring the nitrate content of samples of soil or chalk removed in successive 0.33 m increments to a depth of 8 m below an experimental site at Hurley, Berkshire, UK. Management of the site is summarized in Table 1. The site was on a loam of the Frilsham series[12] overlying Upper Chalk which occurs at a variable depth between 0.7 and 1.3 m. Some properties of the top soil (0–20 cm) are:

Table 1 Management of the experimental site

Date	Plot 1 Cut ryegrass sward	Plot 2 Grazed ryegrass sward
January 1974–April 1976	Fodder maize* which received cattle slurry and farm-yard manure; annual input of N was estimated to be 450 kg ha^{-1}	
April 1976–April 1977	Year during which the swards (each 0.123 ha) described below were established	
April 1977–December 1982	Cut perennial ryegrass† sward to which 420 kg N ha^{-1} as ammonia nitrate was applied annually. The sward was cut once very 4 weeks during the season April to October	Grazed perennial ryegrass† sward to which 420 kg N ha^{-1} as ammonium nitrate was applied annually. The sward was grazed rotationally (1 week in 4, April to October) by yearling steers. Average stocking rate was 9.3 head ha^{-1}
December 1982–present	Swards ploughed and planted to spring barley‡ (April 1983) and winter wheat§ (September 1983). A total of 80 kg N ha^{-1} was applied in 1983

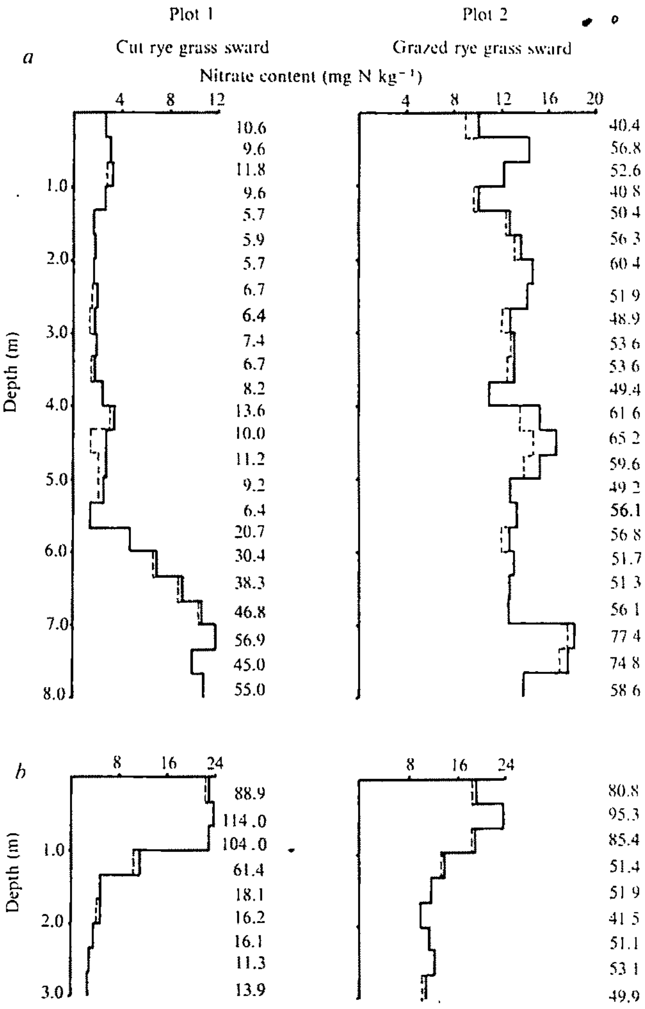

Fig. 1 Nitrate content (mg N kg^{-1}) of samples from successive depths below cut and grazed ryegrass swards (details in Table 1); *a*, before the swards were ploughed in December 1982; *b*, 12 months after ploughing and one crop of spring barley. The numbers alongside each profile are the nitrate concentrations in solution (mg N l^{-1}) at each depth. Values are the arithmetic means of five observations at each depth. The dashed lines indicate the geometric mean where this differed from the corresponding arithmetic mean by more than 0.3 mg N kg^{-1}. The mean values of nitrate content within the 0–1 m depth of each profile derived from the five replicates obtained in the present study were not significantly different from those derived from up to 39 samples removed from a similar depth in a preliminary study[19]. Samples for nitrate analysis were obtained using a power-driven flighted auger drill (Mobil Drilling Co., Indianpolis, USA) mounted on a Land Rover. Nitrate was extracted within 2 h of collection by blending 100-g sub-samples with 200 ml 2 M KCl. The supernatant solution was recovered after 2 h by filtration (Whatman No. 1) and its content of nitrate plus nitrite was determined using an automated colorimetric procedure based on the Griess-Ilosvay Cd-reduction method[21]. Nitrate comprised >99% of the nitrate plus nitrite content of extracts. The water content of samples was determined gravimetrically by drying in a forced air oven at 90 °C for 4 days.

*p*H, 6.0–6.5; bulk density, 1,250 kg m^{-3}; organic carbon, 2.2–2.4%; total N, 0.25–0.28% (ref. 13). The bulk density of the sub-soil to a depth of ~1 m was 1,410 kg m^{-3} while that of chalk at depths >1 m ranged from 1,370 to 1,610 kg m^{-3} with a mean of 1,530 kg m^{-3} for 10 samples. The mean annual precipitation and potential evapotranspiration since 1974 were 694 and 500 mm, respectively[14,15].

The nitrate content of samples removed from below the grazed sward to a depth of ~6 m in December 1982, was consistently greater than that in samples below the cut sward to the same depth (Fig. 1*a*). Although Macduff and White[16] have shown a log-normal distribution of nitrate content in soil, little evidence for this was found for the samples of chalk analysed in the present study. There were only small differences between the arithmetic and geometric means of nitrate content in the five replicates from each depth (Fig. 1 and Table 2). Consequently, a normal distribution was assumed during interpretation of the data obtained.

The differences between the mean nitrate contents of each profile to a depth of 6 m were significant at $P<0.01$; the 95% confidence limits on each mean value were generally in the range ±20–30% (Table 2). The nitrate contents of samples from successive depths to 6 m within a particular profile were not significantly different ($P>0.05$). At depths >6 m, the mean nitrate contents below the cut sward increased to values in the range 8.5–12.0 mg N kg^{-1} and were not significantly different from those observed at the same depths below the grazed swards ($P>0.05$).

Between April 1976 and December 1982, a total of 2,155 mm drainage was measured from lysimeters containing profiles of the Frilsham soil and installed within 500 m of the experimental site[14]. Based on a mean volumetric water content of 0.38 (95% confidence limits ±0.011) in the samples removed and assuming simple piston flow, it is estimated that the 1976–77 leaching front associated with the first drainage season following establishment of the experimental swards should have reached a depth between 5.5 and 5.8 m. It was at about this depth that the nitrate content below the cut sward increased to values similar to those observed below the grazed sward. Thus, the similarity in nitrate content below both swards at depths >6 m apparently reflected the uniformity in management of the site before April 1976, when substantial amounts of waste from winter-housed cattle were applied (Table 1).

The average annual loss of nitrate from the experimental swards can be estimated by relating the mean nitrate content of samples from depths <5 m to the bulk density of material removed and to an estimate of the annual rate of water movement through the profile. Based on the above considerations, the rate of water movement between 1976 and 1982 was ~0.8 m yr^{-1}, a value similar to others derived in studies at sites overlying chalk in south-east England[6,10]. Hence, the average amounts of nitrate leached (nitrate content × bulk density × 8 × 10^{-3}) were 29 and 162 kg N ha^{-1} yr^{-1} for the cut and grazed swards, respectively. Nitrate leaching associated with the return of cattle slurry and farmyard manure during 1974 and 1975 was ~152 kg N ha^{-1} yr^{-1} based on the mean nitrate content of samples from below 6 m.

A substantial increase in the nitrate content of the upper 1.3 m of each profile was observed in December 1983, 12 months after

Table 2 Typical data for the nitrate content of samples from selected depth intervals within the profiles of nitrate content (Fig. 1) below cut and grazed swards

Depth interval (m)	Range	Arithmetic mean (mg N kg^{-1})	s.e.m.	Geometric mean
Cut ryegrass		**December 1982**		
0.33–0.67	1.3–5.1	3.3	0.63	3.0

7.33–7.67	10.2–20.2	17.2	1.81	16.7
		December 1983		
0.33–0.67	21.4–25.7	23.4	1.69	23.4
2.33–2.67	7.9–12.5	10.5	2.14	10.3

the experimental site was ploughed and cropped with spring barley (Fig. 1*b*; Table 1). Mean nitrate contents in the top metre of each profile ranged from 19.4 to 24.0 mg N kg^{-1} dry soil, but differences within this depth and between profiles were not significant and did not reflect the differences in previous management. A discontinuity in the nitrate content of each profile occurred between 1.0 and 1.3 m, an observation in broad agreement with the estimated rate of water movement through the profiles. Although the nitrate front had spread into the upper part of the second metre, probably due to above average rainfall during spring 1983, nitrate contents below this depth were not significantly different from those measured in the corresponding profiles before ploughing (Fig. 1*a*). As 138 kg N ha^{-1} were removed in harvested grain and straw in August 1983, the bulk densities and nitrate contents of the samples removed indicate that between 275 and 310 kg N ha^{-1} in excess of crop requirements was mineralized and nitrified during the first 12 months following ploughing. A further 50 kg N ha^{-1} was present as NH_4^+ at the time of sampling. Much of this inorganic N is expected to be leached below 1 m during the 1983–84 drainage season.

The nitrate concentration in the water moving within each profile can be calculated from the nitrate contents (Fig. 1) and water contents (0.23–0.32 wt/wt) of the samples removed. Concentrations in water draining below the cut sward were in the range 5.4–13.3 mg N l^{-1}, and were above the 'guide level' (5.7 mg N l^{-1}) but generally below the maximum (11.3 mg N l^{-1}) set by the European Community[17] for water for human consumption. Concentrations of nitrate in water draining below: (1) the grazed sward; (2) the experimental area when slurry and farmyard manure were applied; and (3) both plots after they were ploughed, greatly exceeded the upper limit of the range 11.3–22.6 mg N l^{-1} set by the World Health Organisation as 'acceptable'[18].

The present study has shown that substantial amounts of nitrate can be leached from intensively farmed grassland as well as when grassland is ploughed in a ley–arable system. The most striking feature is the effect of ruminant production on nitrate leaching. The annual loss of nitrate from the grazed grass sward was 5.6 times greater than that below the comparable cut sward, despite a common input of fertilizer N and defoliation frequency. The enhanced nitrate movement below the grazed sward can be attributed mainly to the return in urine and dung of as much as 90% of the N in the herbage consumed by cattle[11]. The effect of this is illustrated by the data in Table 3. At the end of the grazing season in October 1982, the mean nitrate content of soil below urine- and dung-affected areas of pasture was 3.2–7.7 times greater than that observed during random sampling across the grazed sward. Additional inorganic N was present as NH_4^+ at this time, much of which had been nitrified by the time the profile was sampled in December at the onset of the drainage season (Fig. 1 and ref. 19). The small amount of residual inorganic N below the cut sward reflected the removal of at least 75% of the applied N in the harvested herbage. However, the cutting and conservation of herbage, and its subsequent use as feed, merely serves to delay the loss of nitrate that can occur after the disposal of slurry and farm-yard manure from winter-housed cattle (Fig. 1*a* and ref. 20).

The effect of ruminant production on the N cycle has received only limited attention in much of the recent work on the use of N in agricultural production[1,5]. The present study and other reports[21–23] show that this effect is substantial, particularly in intensive systems. The amount of fertilizer N applied to the swards used in the present study is typical of the amounts applied to intensively farmed grassland in north-west Europe[24,25]. In England and Wales, 37% of the total area of grass leys now receives >200 kg N ha^{-1} yr^{-1}, with 5% receiving >400 kg N ha^{-1} (ref. 26); responses in animal production have been recorded for inputs up to 600 kg N ha^{-1} (R. D. Baker, personal communication). The data indicate that as the management of grassland is intensified, the amounts of nitrate leached are likely to equal or exceed the range observed for continual arable production (40–100 kg N ha^{-1} yr^{-1}, refs 10 and 27), the losses being greatly accentuated by ruminant production.

Table 3 Nitrate and ammonium contents of soil (0–30 cm) removed from below the cut and grazed swards at the end of the grazing season in October 1982

Sampling position	Number of samples	Nitrate content* Arithmetic mean (mg N kg^{-1} dry soil)	s.e.m.	Geometric mean	s.e.m.†	Ammonium content* Arithmetic mean (mg N kg^{-1} dry soil)	s.e.m.	Geometric mean	s.e.m.†
At random across cut sward	15	2.2	0.29	2.0	1.72–2.22	2.2	0.25	2.0	1.75–2.18
At random across grazed sward	15	7.5	2.23	5.6	4.64–6.63	4.4	2.23	2.2	1.69–2.83
Below urine-affected areas	8	53.5	14.79	43.8	37.11–51.7	56.3	12.56	41.7	33.25–52.25
Below dung-affected areas	8	26.2	8.22	17.8	12.58–25.23	15.1	3.76	10.4	7.09–15.18

* Although the arithmetic and geometric means of the nitrate and ammonium contents of soil below the grazed sward differed by a factor of 1.3–2.0, this was reduced to 1.1–1.2 when individual contents of each form of N were summed for each replicate sample and the mean values of total inorganic N calculated. Hence, the distribution of total N content in October was similar to that of nitrate in December by which time much of the ammonium had been nitrified (see Fig. 1 and ref. 19).

† Lower and upper values on the geometric mean.

We thank J. E. McNeill for technical assistance, K. C. Tyson and D. H. Roberts for help in managing the experimental site and M. S. Dhanoa for advice on the statistical treatment of data. This work was conducted while P.R.B. was a visiting research worker at the Grassland Research Institute and partly supported by the National Research Advisory Council (NZ). The Grassland Research Institute is financed through the Agricultural and Food Research Council, London, and the work was commissioned in part by the Ministry of Agriculture, Fisheries and Food.

A pseudo α-helix from poly(α-isobutyl-L-aspartate), a nylon-3 derivative

J. M. Fernández-Santín, J. Aymamí, A. Rodríguez-Galán, S. Muñoz-Guerra & J. A. Subirana

Unidad de Química Macromolecular del Consejo Superior de Investigaciones Científicas, Escuela T. S. de Ingenieros Industriales de Barcelona, Diagonal 647, Barcelona 08028, Spain

Derivatives of nylon-3, with the general formula given in Fig. 1, crystallize as extended chains, producing sheets similar to those found in polypeptides in the β-conformation[1–3]. Nylon-3 itself (R=H, poly-β-alanine) crystallizes as extended chains[4]. However, given the similarity of the chemical structure, we decided to search for conformations related to the α-helix in this type of compounds. We show here that the nylon-3 derivative poly(α-isobutyl-L-aspartate) can adopt a helical structure similar to an α-helix. The turn has 3.25 residues, equicalent to 13 main chain atoms, whereas the α-helix has 10.8 atoms per turn. This is the first time that a helical structure has been observed in a polyamide, other than in the conventional polypeptides and proteins.

Poly(α-isobutyl-L-aspartate) was prepared using the method described by Yuki *et al.*[3]. A stretched fibre of this compound gave the X-ray diffraction pattern shown in Fig. 2 which can be

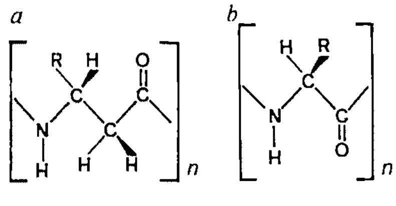

Fig. 1 Comparison of a segment of a nylon-3 derivative of the type described here (*a*) with a peptide unit in a protein (*b*). In *a*, $R{=}COOCH_2CH(CH_3)_2$. The lateral group R is on the opposite side to that in proteins, as it would be in polypeptide chains prepared from D-amino acids. The polymer was obtained by polycondensation of the pentachlorophenyl ester of α-isobutyl-L-aspartate hydrobromide according to Yuki *et al.*[3]. Its intrinsic viscosity is 0.57 dl g^{-1} in dichloroacetic acid at 25° which corresponds to a molecular weight of 90,000 if the equation for poly(γ-benzyl-*L*-glutamate) is applied[6].

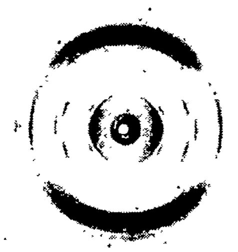

Fig. 2 X-ray diffraction pattern of a fibre of poly(α-isobutyl-L-aspartate) stretched from a chloroform solution. The stretching direction is on the meridian. Equatorial reflections correspond to an hexagonal unit cell with $a = 13.50$ Å. This crystallographic system provides additional evidence for a helical structure, because an extended structure should not pack in the hexagonal system. The first and fourth layer lines are clearly visible in the picture, with spacings of 19.9 and 4.98 Å respectively, which indicate a pitch for the helix of 4.98 Å. The structure contains 13 monomer units in four turns of the helix.

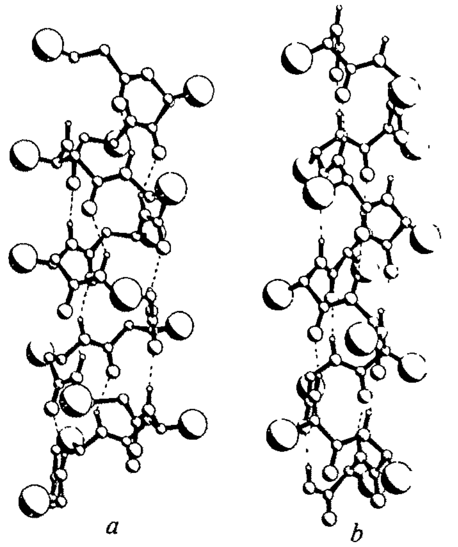

Fig. 3 Comparison between the left-handed helix observed in poly(α-isobutyl-L-aspartate) (*a*) and the conventional α-helix (*b*), constructed in this case with D-amino acids for a more adequate comparison. The larger spheres indicate the side chains. The smallest spheres correspond to the hydrogen atoms involved in hydrogen bonds, which are indicated as dotted lines. The rest of the hydrogen atoms are not shown. The model was built and refined using linked-atom-least-squares methodology[7].

Helix parameters: unit height $h = 1.53$ Å; unit twist = 110.8°; pitch, 4.98 Å. r, ϕ and z are the cylindrical coordinates.

interpreted as a helix. The main argument in favour of such interpretation is that a weak layer line is observed with a spacing of 19.9 Å, together with a strong layer line at 4.98 Å. The first spacing corresponds to the true repeat of the structure, whereas the 4.98-Å spacing corresponds to the pitch of the helix. There should be a whole number of units in the 19.9-Å spacing. Model building indicates that there are 3.25 units in a complete turn of the helix and 13 units in the true repeat of four turns. Additional support for this interpretation comes from the hexagonal packing system found, which is typical of helical structures. The calculated density for such structure is 1.19, which is in reasonable agreement with the measured density of 1.17.

A model of the suggested structure was built and its coordinates are given in Table 1. It is shown in Fig. 3 together with the conventional α helix found in polypeptides. The following conclusions can be made from such a comparison: (1) The α helix has 10.8 main chain atoms per turn whereas the helix described here has 13. (2) The orientation of the hydrogen bonds is the same in both helices, so that they both have a polar structure. (3) To achieve such orientation, the nylon-3 derivatives maintain in the helix a conformation similar to that found in the extended chain, whereas in the α-helix there is a considerable rotation around the N–C and C–C bonds of the main chain so that consecutive peptide units have the same orientation. (4) The orientation of the side group with respect to the main chain in poly(α-isobutyl-L-aspartate) is similar to that found in a left-handed α-helix built from D-amino acids, in fact, our calculations show that there are fewer steric hindrances in a left-handed rather than a right-handed helix. (5) The average radius of the main chain atoms in the helix we have described is 2.4 Å, a value significantly larger than that found in the α-helix (1.8 Å), as it is apparent from Fig. 3.

Our studies show, therefore that it is possible to obtain conformations similar to the α-helix in nylon-3 derivatives. In fact, given the higher degree of flexibility provided by the additional carbon atom in the main chain, it is likely that other conformations (similar to either ω or π helices[5]) may be found in these compounds. To our knowledge it is the first time that a helical conformation has been found in a nylon derivative.

Replacement of oak forest with pine in the Himalaya affects the nitrogen cycle

J. S. Singh, Y. S. Rawat & O. P. Chaturvedi

Department of Botany, Kumaun University, Naini Tal 263 002, India

Pine and oak are the two predominant evergreen forests in the central and western Himalaya between altitudes 1,200 and 2,200 m. The pine is a light-demanding, fire-adapted but fire-promoting species. The surface fires averaging once every 2 or 3 years cause substantial nitrogen losses in pine forest. Pine forest naturally occurs on the driest and rockiest slopes, and has spread greatly under the influence of cutting and burning, replacing oak forest in vast areas. Oak forest is non-inflammable but has suffered a good deal from fire spreading from the pine forest[1]. Deforestation has also accounted for loss of oak forest[1–3], and although the replacement of oak by pine is common[1,2], the reverse has not been observed. Our studies indicate that the greater nutrient-conserving ability of pine and the creation of a nitrogen shortage makes it difficult for oak to re-invade areas occupied by pine[4–8].

The pine (*Pinus roxburghii* Sarg.) forest was studied on four sites and the oak (*Quercus leucotrichophora* A. Camus & *Q. floribunda* Lindl.) forest on three sites, between 1,300 and 2,100 m altitude, 29°24′–29°37′ N lat. and 79°28′–79°38′ E long. The annual rainfall is 1,160–2,298 mm, and mean annual temperature 13–18 °C. All sites have mature (60–200-yr old) forests with uneven-aged trees. Soil in the pine forest is residue from chlorite–sericite schists and micaceous quartzites, weakly podzolic (*p*H 5.7), and sandy loam of composition 15.2% clay, 18.3% silt, 66.5% sand, 2.28% organic carbon and 0.18% total nitrogen. Oak forest soil is residual brown earth (*p*H 6.0), derived from limestone, quartzite and shales, and sandy loam (sand 76%, silt 13% and clay 11%) with 4.51% organic carbon and 0.51% N.

Biomass was estimated using allometric equations, and the density and diameter of trees. Net production was calculated from diameter increments and litter fall. One-fifth of the leaf fall was assumed to be equal to fine root mortality[9], and this was added to the estimate of net production. All plant components were analysed for nitrogen and phosphorous. Gross uptake was calculated by multiplying the net production of different components by their respective nutrient concentration. The amounts of N and P transferred to the forest floor were estimated from litter fall and its nutrient concentration, and from canopy leaching. Standard error ranged between 3 and 6% of the mean values. The differences in nutrient concentration and dry weight of mature live and freshly senescent leaves were used to calculate the per cent withdrawal of N and P.

Dry matter, and the amounts of N and P for the two forests are given in Table 1. Dry weight of the standing vegetation in the oak forest was 1.8 times and N 3 times that of the pine forest. The amount of P was roughly similar. Soil (to a depth of 20 cm) under oak forest had 1.5 times as much N as in pine forest. The C:N ratio of oak soil was 8.5 and of pine soil 14.

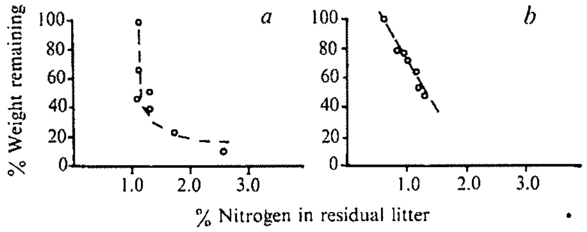

Fig. 1 Relationship between per cent weight remaining and N concentration of residual leaf litter after different time intervals during a year. *a*, Oak (*Q. leucotrichophora*) leaf litter enclosed in litter bags and placed on the forest floor of an oak forest; *b*, pine leaf litter enclosed in litter bag and placed on the forest floor of a pine forest.

§ Includes reproductive litter.

Of the total N and P in the system, pine vegetation had, respectively, 22 and 40%, and oak vegetation 37 and 41%.

Net production was 8% of the tree layer biomass for the pine forest and 4% for the oak forest. Gross uptake of nitrogen was higher for the oak forest.

Substantial quantities of N and P were reabsorbed from old leaves before abscission in pine. Thus, 37% and 33% of gross uptake of N and P, respectively, were derived from nutrients reused from previous years in pine compared with 10% N and 11% P in oak. For foliage alone, 51% N and 52% P were reused for production of new leaves in pine, but 13.2% N and 8.5% P in oak. The withdrawal of nutrients before abscission maintains a relatively mobile pool within the living biomass of the ecosystem, and allows the plant to use the same unit of nutrient to build successively new leaves or plant parts[10,11]. Increased internal redistribution of nutrients is considered to be an adaptation to impoverished soils[12–15].

The net uptake of N and P from the soil is lower than the nutrient pool accumulated in net production (gross uptake) by the amount reused from previous years[16]. Net uptake in oak was relatively low for P, but for N it was considerably higher than in pine.

The return of N and P amounted to 3–6% of the quantities in the vegetation pool. The dry matter : nitrogen ratio of leaf litter fall was 105 in pine and 60 in oak. Thus the efficiency of litter production per unit of N was greater in pine compared with oak. Vitousek[11] suggested that nitrogen efficiency of litter production varies as an inverse function of the nitrogen available.

The high, dry matter : nitrogen ratio of the litter and high, C:N ratio of the soil in pine forest reduce the rate of litter decomposition and increase the fuel load on the forest floor. In addition, the decomposers of litter of a high, dry matter : nitrogen ratio may immobilize available N from the soil solution. Weight loss and the N concentration of residual litter of pine and oak enclosed in litter bags and placed on respective forest floors were studied for 1 yr. Figure 1 clearly indicates a marked immobilization of N in decomposing pine litter. The dynamic available N pool in the soil at any point in time is usually only a small proportion of total N[10,17] and its immobilization by microbes may intensify the N shortage in nitrogen-poor ecosystems. We suggest that this is the main reason why pine is able to resist reinvasion by oaks. As argued by Vitousek[11], low N availability caused by the immobilization by microbes may lead to increased efficiency of N use and production of litter with still higher dry matter : nitrogen ratio. Recurring fires in the pine forest lead to marked N losses through volatilization, augmenting the N shortage.

Oak has a relatively heavy demand for N and cannot succeed in N-poor soil. Through the return of N-rich litter and rapid mineralization, oaks maintain high soil fertility. Heavy lopping of oaks for fodder and cutting for fuel cause large canopy gaps and reduce leaf fall and hence N return, making the conditions suitable for invasion by pine.

The retention of N is specially pronounced in the oak forest (Table 1). Thus, in this forest the N pool may be more severely altered by deforestation. In such systems, replacement of N reserves will be essential to avert a long-term decline in productivity following deforestation[10]. In view of the above, the widespread replacement of mixed rain forests with plantations of conifers in the tropics and subtropics should be viewed with caution.

Species variation and the mechanism of pressure–anaesthetic interactions

E. B. Smith, F. Bowser-Riley, S. Daniels, I. T. Dunbar, C. B. Harrison & W. D. M. Paton*

Physical Chemistry Laboratory, South Parks Road,

Oxford OX1 3QT, UK

The mechanism of general anaesthesia has proved difficult to elucidate (see ref. 1 for a review), although the relative potencies of anaesthetic agents have been used to establish that the site at which anaesthetics act is hydrophobic in nature[2]. One further clue to their mode of action is that the effects of anaesthetics on vertebrates can be eliminated by pressures of ~100 atm (refs 3, 4). However, the effects of anaesthetics are not always reversed in model systems, where there is evidence that the pattern of pressure reversal varies significantly[5–10]. We now find that pressure fails to reverse the effects of anaesthetics on the freshwater shrimp (*Gammarus pulex*), although the sensitivity of these crustaceans to anaesthetics is comparable with that of higher animals. This is hard to reconcile with traditional bio-physical mechanisms and indicates that anaesthetics may act at a specific protein site rather than having a general effect on cell membranes. The pharmacology of pressure in mammals seems to be more similar to that of strychnine than of any other central stimulant[11]. As glycine, whose action is blocked by strychnine, is absent as a neurotransmitter in the arthropod central nervous system, we believe that this substance may be involved in determining pressure–anaesthetic interactions in vertebrates.

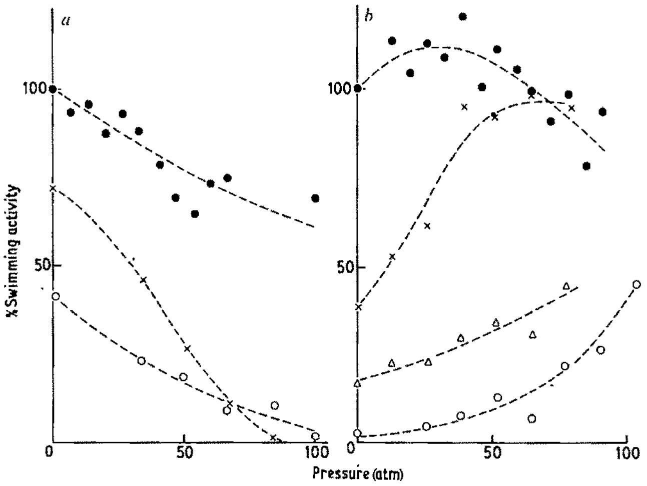

Fig. 1 *a*, Effect of pressure on *G. pulex* in the presence of ethanol (the lines are merely visual aids). *b*, Effect of pressure on larvae of *R. temporaria* in the presence of ethanol. ●, No anaesthetic; ×, 0.02 M ethanol; △, 0.265 M ethanol; ○, 0.275 M ethanol.

The effects of pressure and anaesthetics on the stimulated swimming activity of freshwater shrimps (*G. pulex*) and tadpoles (the larvae of *Rana temporaria*) were compared in similar experimental conditions. The animals were observed in glass cells, 5 cm long, designed to fit into a high-pressure chamber. The lower portion of the cells consisted of a trough of 1 cm^2 cross-section fitted with tungsten electrodes. Above the trough was a larger volume with steep sides so that anaesthetized animals fell into the trough which, when an electrical stimulus was applied, was a region not favoured by unanaesthetized animals. Five animals were placed in the cell and each determination of activity consisted of 20 observations taken at 10-s intervals. The fraction of the total population remaining above the trough was taken as a measure of swimming activity. Optimum swimming activity was obtained by the application of 5-V pulses of 0.1 s duration every 2 s for shrimps and similar pulses of 10 V for tadpoles. In these conditions the standard deviation of the measurements of activity was found to be ±7%. The experiments were carried out at 18 °C. Anaesthetics were added directly to the cell and up to 30 min was allowed for equilibration. Pressure was applied using helium gas; this is an acceptable agent because any anaesthetic effects that it might induce are not significant at the pressures used here[12].

For shrimps, the relative potencies of the anaesthetics studied—ethanol, ether, chloroform, halothane and sodium pentabarbitone—were very similar to those determined with other organisms (Table 1). Furthermore, the absolute potencies for shrimps and tadpoles are close to those reported for other species. The effect of pressure, in the absence of anaesthetics, on the swimming of the shrimps was moderately to reduce activity by ~30% at 100 atm and no hyperactivity was observed (Fig. 1). With all the anaesthetics used, the application of pressure further reduced swimming activity. In no instance was there any evidence of pressure reversal; indeed, the decrease in activity seemed greater than would be predicted by the simple addition of the effects of pressure and anaesthesia. Tests were made to confirm that the effects of both pressure and the anaesthetics were reversible.

The experiments with tadpoles were carried out in a similar manner. Pressure alone caused moderate hyperexcitability. When anaesthetics were present, the application of pressure dramatically restored swimming activity (Fig. 2). This effect had been previously observed qualitatively with tadpoles[13] and also with mice and newts[3]. Because tadpoles behave as expected in the same experimental conditions, it is unlikely that the anomalous behaviour of the shrimps is due to the experimental procedure.

This behaviour of the shrimps parallels that of the pleopod frequency of *Marinogrammarus marinus* which exhibits a gradual decline when exposed to 3.9 mm Hg pressure of halothane and which is potentiated by pressure[5]. For the brine shrimp, *Artemia salina*, the locomotor activity showed a lower relative decline on the application of pressure in the presence of anaesthetics than occurred in their absence. However, it was concluded that neither pressure reversal of anaesthesia nor a narcotic amelioration of the pressure effect had occurred[14].

The relative potencies of the anaesthetics for shrimps, as for other organisms, point clearly to a hydrophobic site of action. The absolute potencies for shrimps and tadpoles are sufficiently close to suggest that in both species the anaesthetics act at physically similar sites by a common mechanism. However, the effects of pressure on anaesthesia in the two species suggests that very different mechanisms are involved. The effects of pressure on a process can be interpreted in terms of an associated volume change, ΔV (ref. 15). For a simple equilibrium, defined by equilibrium constant K,

$$\frac{\mathrm{d}\ln K}{\mathrm{d}P}=\frac{\Delta V}{RT} \qquad (1)$$

The association of ΔV with physical changes in the system depends on the model adopted[1]. For vertebrates the volumes calculated from this equation, or obtained from more sophisticated models such as the constant volume hypothesis[3], are positive and in the range 50–100 cm^3 per mole of anaesthetic[1,16]. This range is in keeping with the volume change associated with anaesthetic interaction at a hydrophobic region[14]. Conversely, the data for the shrimps, though not sufficiently precise to define quantitatively the associated volume change, indicate that the ΔV obtained from equation (1) is small and possibly negative.

Serious consideration has been given to two types of sites at which general anaesthetics might act. Traditionally, anaesthetics have been thought to act by a general perturbation of the lipid bilayers of the cellular membrane[17]. More recently, hydrophobic sites associated with protein molecules have been proposed[1]. This idea has drawn support from investigations of the complex responses of bacterial luciferases to clinical concentrations of general anaesthetics[18]. Anaesthetics at low concentrations can enhance light production from the enzyme by facilitating substrate binding and at higher concentrations can decrease the light emission by blocking the binding of an aldehyde necessary for luminescence[19]. The effects are observed both *in vivo* and with the extracted enzyme. The reduction of light intensity caused by anaesthetics can be reversed by the application of pressure. The very different responses observed in shrimps and tadpoles are not easily explained in terms of general membrane sites, but the differences could be consistent with more specific binding at protein sites if, for shrimps, anaesthetics induce a conformational change in a protein which leads to a negative ΔV.

The pharmacology of pressure, as elucidated from studies of pressure-induced convulsions in mammals, has been found closely to parallel that of strychnine[11]. This compound is believed to act primarily on postsynaptic inhibition, which is mediated by the neurotransmitter glycine. Crustaceans are insensitive to strychnine[20] and have a central nervous system in which glycine is not present as a neurotransmitter[21,22]. Thus, we propose that pressure reversal of anaesthesia, as observed in vertebrates, may involve effects of pressure on strychnine-sensitive processes, possibly through changes brought about in the glycine receptor protein. Although we cannot rule out the possibility that pressure reversal results from an independent action of pressure leading to a physiological rather than pharmacological antagonism of anaesthesia, most models of pressure reversal assume that pressure and anaesthetics act at the same site[1,4]. This suggests that in vertebrates, as in luminous bacteria, both pressure and anaesthetics act on the same relevant protein. By analogy with the luciferase model, anaesthetics could facilitate the binding of glycine to its receptor protein, a process that could play a part in determining those aspects of general anaesthesia which are reversed by pressure, including loss of consciousness in mammals.

Rules for neural development revealed by chimaeric sensory systems in crickets

W. W. Walthall & R. K. Murphey

Neurobiology Research Center, State University of New York at
Albany, 1400 Washington Avenue, Albany, New York 12222, USA

Many sensory systems are organized so that the afferent projection forms a topographic map of the sensory surface within the central nervous system (CNS)[1,2]. The information necessary to create such a map may be available to the neuronal cell body based on its position in the receptor array, and this 'positional information' is translated into an axonal arborization in the proper part of the CNS[3–6]. To study how the location of a cell body within the sensory surface determines the termination pattern of its axon within the CNS, we have transplanted epidermis, containing identified sensory neurones, from a black cricket to a tan cricket. As we report here, when epidermis is transplanted to an unusual location in the receptor array, newly generated neurones are produced along the borders of the graft. These neurones arborize in locations that are appropriate neither to their new position nor to their original position in the array, but rather to a position somewhere in between. This is direct evidence for the idea that positional information guides the differentiation and ultimately the synaptic connections of insect sensory neurones.

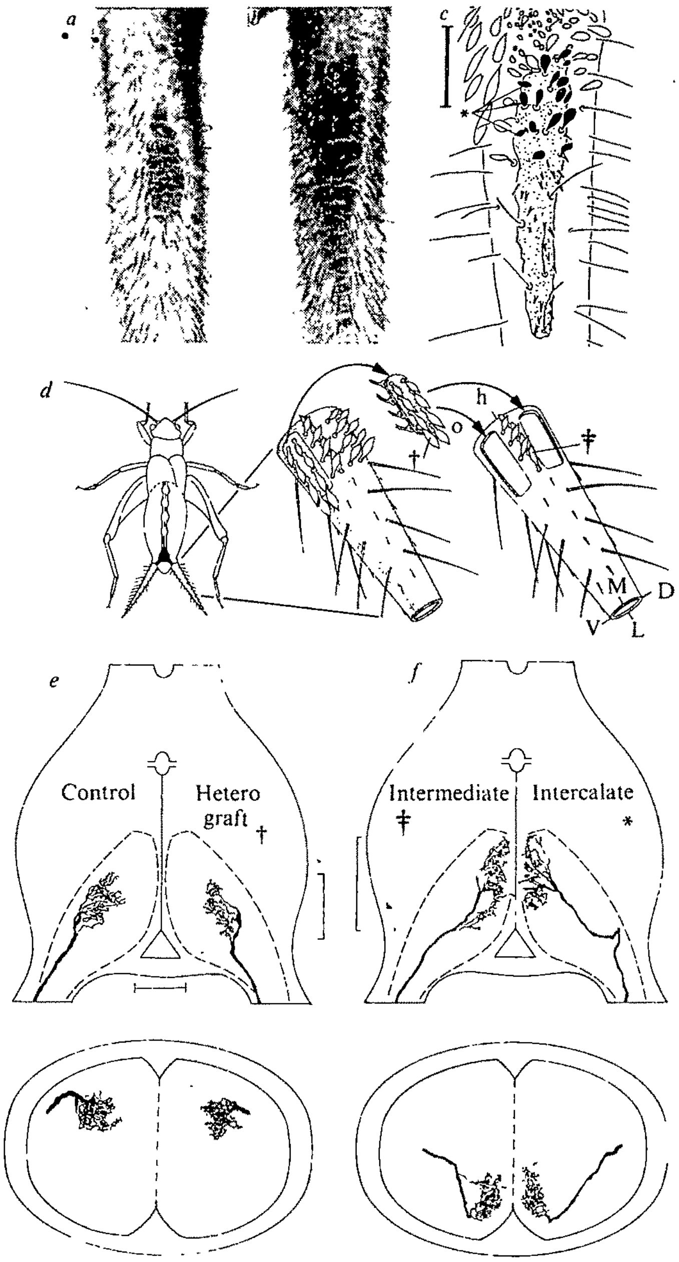

Fig. 1 Transplantation of neurones and characterization of their axonal arborizations. *a*, *b*, Light micrographs of chimaeric cerci. *a*, Ventral view of a cercus showing an orthotopic graft. The graft is schematized and indicated by 'o' in part *d*. *b*, Dorsal view of a cercus showing a heterotopic graft. This graft is schematized and indicated by 'h' in part *d*. *c*, Camera lucida drawing of the heterotopic graft shown in *b*. Transplanted clavate hairs (club-shaped) lie in the centre and to the right of the graft. *, Intercalated clavate hairs, as shown by their smaller size and by examining the graft for new hairs, after each moult. *a* and *c* are shown at the same magnification; scale bar, 500 μm. *d*, Schematic diagram illustrating the methods. The cutaway view of a cricket outlines the abdominal nervous system. The last abdominal ganglion, site of termination for all clavate neurones, is darkened. In each graft the two most ventral rows of clavate hairs and the surrounding epidermis were moved from a donor *G. bimaculatus* to a host *A. domesticus*. The graft consisted of a piece of tissue, 100 μm × 250 μm, transplanted when both crickets were in the 6th instar. Phenyl thiocarbamide (Sigma grade II), penicillin G (Sigma) and streptomycin sulphate (Sigma) powders were combined by weight in a ratio of 2:1:1 and added directly to the wound to guard against infection and melanization. *e*, *f*, Comparison of the axonal arborizations of normal and transplanted neurones. *e*, The axonal arborization of a neurone transplanted to a foreign location (hetero-graft), indicated by † in *d*, is compared with the equivalent neurone on an unoperated cercus (control). *f*, The terminal arborization of an intercalated sensory neurone (intercalate) innervating a clavate hair along the ventral margin of the dark epidermis (not actually grafted but intercalated) (*c*, *) is compared with a neurone (intermediate) normally found between the new graft site and its site of origin (*d*, ‡). The upper panels in *e*, *f* represent dorsal views; the lower panels represent transverse views. The transverse views were reconstructed from serial sections (the region reconstructed is indicated by a bracket next to the dorsal view). The dashed lines in the dorsal views outline the target area, the cercal glomerulus, for clavate neurones. *e* and *f* are shown at the same magnification; scale bar, 100 μm.

An orderly array of club-shaped sensilla called clavate hairs, located on the cercus of crickets[7,8], forms the initial stage of a neuronal circuit that apprises the insect of its position with respect to the gravitational field[9]. Each clavate hair is innervated by a single epidermally derived sensory neurone whose axon projects into the CNS. As a group, these sensory neurones form a topographically ordered neuronal projection[8]. Analogous individual receptors can be identified on two species of cricket, *Acheta domesticus* and *Gryllus bimaculatus*. The only detectable difference is one of colour; *A. domesticus* epidermis is tan, whereas *G. bimaculatus* is black. To demonstrate the similarity of the two species, we transplanted strips of tissue containing the cuticle, underlying epidermis and receptors and associated sensory neurones from the cercus of a black cricket, the donor, to an analogous position (orthotopic graft, Fig. 1*d*, 'o') on the cercus of a tan cricket, the host. The transplanted tissue survived as a contiguous sheet of black epidermis; the borders between donor and host were sharply delineated and the hairs retained their colour differences (Fig. 1*a*), thus allowing donor-derived clavate hairs to be readily distinguished from their host-derived neighbours.

Because a stereotyped series of cell divisions produces a hair cell and its associated sensory neurone from a single epidermal cell[10], a marked hair is always innervated by a sensory neurone of the same genotype. Thus, *G. bimaculatus* epidermis provides a marker not only for cuticle, but also for the underlying sensory neurone. When identified donor neurones within the graft were stained, they possessed axonal arborizations indistinguishable in size and location from the equivalent host neurone on the undisturbed cercus (Table 1). Apparently, there are no species-specific differences between donor sensory neurones and the host CNS to prevent regeneration of normal axonal arborizations.

We have taken advantage of these similarities to study whether the position of the soma on the body surface determines the axonal arbor within the CNS. Donor sensory neurones were transplanted into non-equivalent areas of the cercus (heterotopic grafts), and they then regenerated arbors characteristic of their original position. For example, when ventro-medial donor tissue was transplanted to a dorso-medial location on the host (Fig. 1*d*, 'h'), the donor tissue healed into place and transplanted neurones terminated in a location within the CNS appropriate to their position of origin (Fig. 1*e*, hetero-graft). In fact, these heterotopic neurones are virtually indistinguishable from the equivalent neurone on the undisturbed cercus (Fig. 1*e*, control). Thus, some intrinsic property of the neurone allows it to regenerate an axonal arbor to its former location even after its soma has been transplanted to a foreign location.

How does a neurone obtain this instruction about where to terminate? If the position of origin of the soma is important in assigning the axonal arborization of a neurone to the proper target area, a translocation of the neurone or its precursor before differentiation (or determination) should assign it a new identity and lead to an axonal arbor in a location appropriate to its new position[6,11]. Heterotopic grafts trigger the proliferation of new epidermal cells along the border between donor and host tissue[12–14], as is suggested in Fig. 1*a* and *b*, which compare an orthotopic and a heterotopic graft: even though the donor tissues were initially the same size (0.025 mm^2), the heterotopic graft grew significantly larger (0.343 mm^2) than the orthotopic graft (0.139 mm^2, Table 1). It has been demonstrated, using external cuticular markers, that this new tissue represents positions normally located between the donor and the host and the epidermis is thus said to 'intercalate' the intermediate positions[12–14].

When a heterotopic graft was created by transplanting a piece of donor epidermis containing identified clavate hairs to an unusual position on the host (Fig. 1*d*, 'h'), we noticed that new receptors often differentiated along the margins of the graft (Fig. 1*c*, asterisk). These new receptors could be identified by examining the graft after each moult; they were smaller and were not present at the time of the transplantation. Staining the axonal arbors of the sensory neurones associated with these intercalated receptors provides a critical test of the idea that sensory neurones are specified by positional information: if donor-derived neurones of 'intermediate' phenotype are produced, this supports the hypothesis that position of origin determines target area. When donor-derived neurones, associated with black hairs along the ventral border of the heterotopic graft (Fig. 1*c*, hairs indicated by an asterisk) were stained (Fig. 1*f*, 'Intercalate'), they projected to an area normally associated with neurones located in an area between that of the apposed host and the donor tissue (such as those innervating the hair indicated in Fig. 1*d*,‡). Of 11 intercalated neurones stained in 11 different specimens, 10 could be recognized as having intermediate phenotypes (Table 1). Equally important, none of these neurones had the phenotype of the transplanted neurones (located more centrally in the graft, for example, Fig. 1*e*, heterograft). This result strongly supports the idea that relative position of the neuronal cell body, at or near the time of its terminal mitotic division, determines the shape and location of the neurone's axonal arborization in the CNS.

Bate[6,15] suggested, from physiological determinations of neuronal connections, that the position of a sensory neurone on the epidermis of an insect regulates the central connections it makes. The present results and related work[7,8,16] provide strong support for Bate's hypothesis because they show first that the axonal arborizations are physically distinguishable within the CNS, and second that the topography of the afferent projection is controlled by the position of origin of the cell body. The idea is very similar to Sperry's chemoaffinity hypothesis[3], developed to explain results regarding the development of the projection from eye to brain in amphibians and fish. Subsequent work has led to considerable debate[4,17–19] over the exact role of positional information in the formation of the retinal projection, primarily because it is so difficult to identify and keep track of the neurones involved. In contrast, the individual sensory neurones of the cricket cercus, which are easily identifiable, have allowed us to demonstrate clearly that soma position is translated into a property that guides the elaboration of an axonal arborization in a particular location of the CNS. Because the location of the axonal arborization is ultimately associated with synaptic connectivity[16], we conclude that positional information guides connectivity.

Table 1 Results of grafts between *A. domesticus* and *G. bimaculatus*

Type of graft	No. of successful grafts	Average size (mm^2)	Successfully stained neurones	Type of arbor
Orthotopic	11	0.139 ± 0.063 ($n = 8$)	5 Transplanted neurones	Normal
Heterotopic	30	0.343 ± 0.214 ($n = 17$)	6 Transplanted neurones	Normal
			11 Intercalated neurones	Intermediate*

The difference in average size between the two groups was significant at the 0.05 level ($t = 2.08$, d.f. = 22). Some of the chimaeric cerci were used for histological work and could not be included here.

* This arbor is located ventro-medially in the neuropil (see Fig. 1*f*, 'intermediate').

We thank Professor F. Huber for providing the *G. bimaculatus*, Dr J. P. Bacon, L. Eisele, G. A. Jacobs, S. E. Johnson, H. Rothenberg and D. S. Sakaguchi for advice, and R. Loos, R. Speck and L. Welch for assistance in preparing the manuscript. This work was supported by NIH award NS-15571 to R.K.M.

Evidence for neurotensin as a non-adrenergic, non-cholinergic neurotransmitter in guinea pig ileum

Michel Goedert, John C. Hunter & Mary Ninkovic

MRC Neurochemical Pharmacology Unit,
Medical Research Council Centre, Medical School, Hills Road,
Cambridge CB2 2QH, UK

Neurotensin is a 13-amino acid peptide that is widely distributed in central and peripheral tissues of various mammalian species[1]. In peripheral tissues, the highest concentration of neurotensin-like immunoreactivity is found in the ileum, where it is present in endocrine-like cells and nerve fibres[2–4]. The longitudinal smooth muscle layer of the guinea pig ileum, where neurotensin has both a direct relaxant and an indirect contractile action, has been used extensively as a biological assay system for neurotensin[5]. We report here that the majority of specific ^{3}H-neurotensin binding sites is present in the guinea pig ileum circular smooth muscle layer, which is known to be innervated by a large proportion of the ileal non-adrenergic inhibitory nerves[6]. Neurotensin produces a dose-dependent, tetrodotoxin-resistant relaxation, whereas the relaxation produced by field stimulation of the inhibitory nerves is frequency-dependent and tetrodotoxin-sensitive. The calcium-dependent potassium channel blocker apamin[7,8] inhibits both the neurotensin- and nerve stimulation-induced muscle relaxation. Incubation of the circular smooth muscle preparation with a neurotensin antiserum substantially inhibited the nerve stimulation-induced relaxation, indicating a direct relationship between the effects of neurotensin and of nerve stimulation.

For receptor autoradiography, adult male guinea pigs (250–400 g, Hartley strain) were stunned, a portion of their terminal ileum was dissected, flushed with cold saline, frozen and sectioned in the transverse plane at 13 μm using a cryostat. The sections were incubated with 2 nM ^{3}H-neurotensin and non-specific binding was defined as that in the presence of 1 μM neurotensin. Following incubation, they were apposed to emulsion-coated coverslips and kept at −20 °C for 2 months. The coverslips were then developed and the tissue sections Nissl-stained. Test-tube binding for ^{3}H-neurotensin was performed by using washed membranes prepared from whole guinea pig ileum. The guinea pig ileum circular smooth muscle preparation was set up as described previously[9]. Contraction of the muscle tone was induced by the tachykinin kassinin (10 nM) and all experiments were performed in the presence of atropine (5 μM), guanethidine (20 μM), indomethacin (1 μM) and mepyramine (5 μM).

When sections through the guinea pig ileum were incubated with ^{3}H-neurotensin, labelling was found in the smooth muscle layers, with a dense band of silver grains in the circular muscle layer and a band of lesser density in the longitudinal muscle layer (Fig. 1). The neurotensin binding sites were further characterized by using a test-tube binding assay for ^{3}H-neurotensin performed on washed membranes of whole guinea pig ileum.

The binding was saturable (Fig. 2*a*) and Scatchard transformation of the specific binding data (Fig. 2*b*) indicated the presence of a single population of binding sites with an equilibrium dissociation constant of 3.4±0.7 nM ($n = 4$) and a maximum number of binding sites of 14±2.6 fmol per mg protein ($n = 4$). The relative potencies of various neurotensin fragments in competing with ^{3}H-neurotensin for its specific binding site were similar to the potencies obtained for these fragments in the circular smooth muscle preparation (Table 1), indicating that the binding properties of ^{3}H-neurotensin were consistent with binding to a physiological receptor.

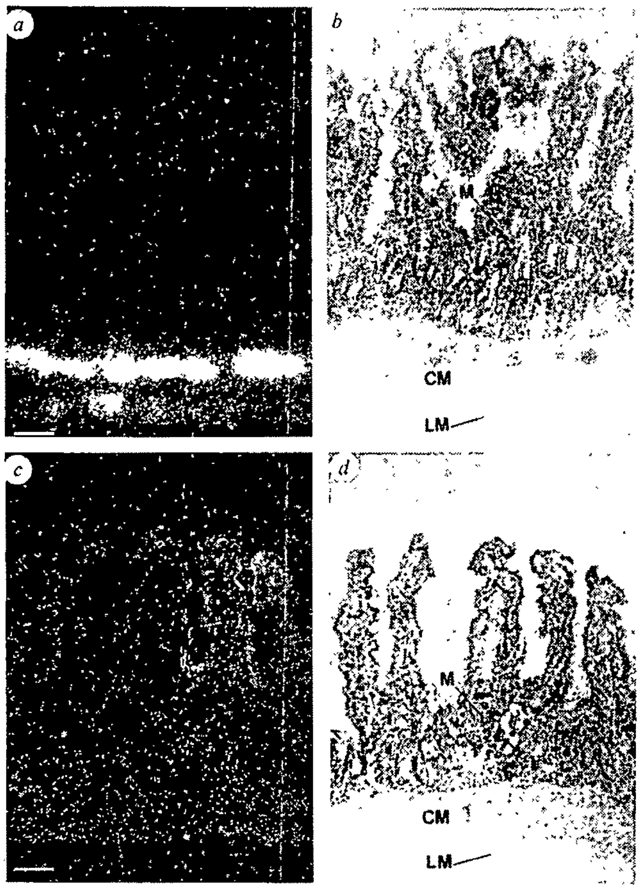

Fig. 1 Autoradiographic localization of ^{3}H-neurotensin binding sites in the guinea pig ileum. *a*, Dark-field photomicrograph of a section incubated in the presence of 2 nM ^{3}H-neurotensin. *b*, Light-field photomicrograph of the Nissl stain of the same section as in *a*. *c*, Dark-field photomicrograph of an adjacent 13-μm section to *a* incubated in the presence of 2 nM ^{3}H-neurotensin and 1 μM unlabelled neurotensin. *d*, Light-field photomicrograph of the Nissl stain of the same section as in *c*. M, mucosa; CM, circular muscle; LM, longitudinal muscle. Note the labelling of the circular and longitudinal muscle layers in *a*. Similar results were obtained for the ilea from six different animals. Scale bar, 100 μm.

Methods: Sections (13 μm) of the guinea pig ileum were pressed onto gelatin-coated slides, melted in place and dried overnight at 4 °C in air-tight boxes with desiccant. The thawed sections were incubated for 10 min at 25 °C in 2 nM [3,11-tyrosyl-3,5-^{3}H]neurotensin (56.3 Ci mmol^{-1}, NEN) in 50 mM Tris-HCl *p*H 7.4, containing 0.1% bovine serum albumin (radioimmunoassay grade, Sigma), 40 mg l^{-1} bacitracin (Sigma) and 1 mM EDTA. Nonspecific binding was defined in adjacent sections as binding in the presence of 1 μM unlabelled neurotensin (Cambridge Research Biochemicals). Following the incubation, the sections were washed twice in cold buffer (2 min each time), dipped into cold water and dried under a stream of cold air. They were then apposed to emulsion-coated coverslips[26] and kept at −20 °C for 2 months. The coverslips were developed in safe-light conditions using Kodak D19 developer and the tissue sections put into Carnoy's fixative, Nissl stained and mounted using Depex. Dark-field photomicrographs were taken of the silver grains and the Nissl stain, respectively. In some experiments, following the incubation with 2 nM ^{3}H-neurotensin, the dried tissue sections were scraped off the slides and the bound radioactivity determined by liquid scintillation spectrometry. The specific binding was 77±9% ($n = 3$) of the total (taken as 100%). The binding of ^{3}H-neurotensin was not affected by 1 μM of the following peptides: neurotensin(1–6), neurotensin(10–13), substance P, vasoactive intestinal polypeptide, somatostatin(15–28) and dynorphin(1–17).

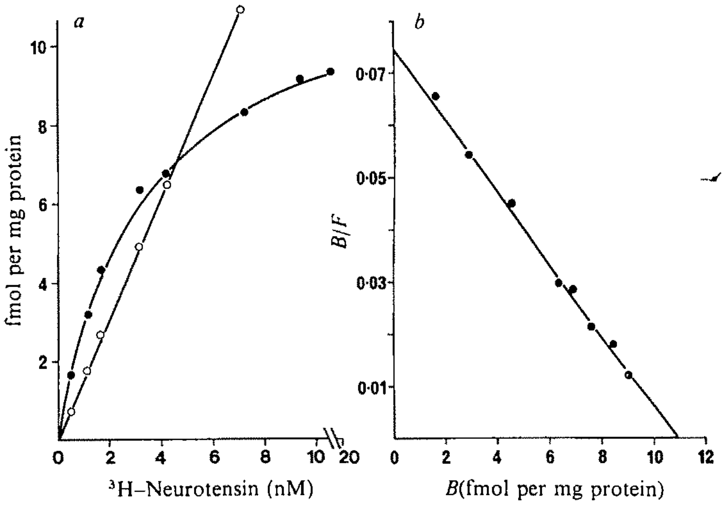

Fig. 2 ^{3}H-Neurotensin binding to a membrane preparation of guinea pig ileum. *a*, ^{3}H-Neurotensin as a function of the radiolabelled peptide concentration. Values were obtained in a single experiment; similar results were obtained in four separate experiments. Nonspecific binding (○) was defined as binding in the presence of 1 μM neurotensin and specific binding (●) was obtained by subtracting the nonspecific from the total binding. *b*, Scatchard transformation of the specific binding data.

Methods: The ileum from adult male guinea pigs was dissected, flushed with cold saline, weighed and homogenized in 10 vol (w/v) of cold 50 mM Tris-HCl *p*H 7.4, with a Polytron at setting 7 for 15 s. After 20 min centrifugation at 50,000*g*, the pellet was resuspended in 10 vol 50 mM Tris-HCl, incubated at 37 °C for 30 min and centrifuged again. The washed pellet was resuspended in 50 mM Tris-HCl *p*H 7.4, containing 0.1% bovine serum albumin, 40 mg l^{-1} bacitracin and 1 mM EDTA to yield a concentration of 10 mg tissue per ml buffer. 1 ml of homogenate was incubated in the presence of ^{3}H-neurotensin at 25 °C for 10 min. At the end of the incubation period the tubes were transferred to ice and filtered immediately under reduced pressure through GF/B glass fibre filters (Whatman) pretreated with 0.2% polyethyleneimine (Sigma) in water. Each of the filters was washed four times with 5 ml cold buffer and the radioactivity determined by liquid scintillation spectrometry. A detailed characterization of the binding assay has been published elsewhere[25]. Proteins were determined according to Lowry *et al.*[27] using bovine serum albumin as the standard.

In the guinea pig ileum circular smooth muscle preparation, neurotensin produced a dose-dependent relaxation of the muscle tone, with an IC_{50} value of 3.6 ± 0.6 nM ($n = 12$, Fig. 3*a*), whereas the relaxation following field stimulation was frequency dependent (Fig. 3*b*). The latter was inhibited by 0.6 μM tetrodotoxin, whereas the muscle relaxation effected by neurotensin was tetrodotoxin-resistant. Both the neurotensin-mediated smooth muscle relaxation (1–30 nM) and the relaxation produced by inhibitory nerve stimulation (1, 2 and 5 Hz) were completely inhibited by 30 nM of the bee venom apamin.

The possibility that the smooth muscle relaxation effected by inhibitory nerve stimulation is due to the release of a neurotensin-like substance was investigated by incubating the circular smooth muscle preparation with a previously described antiserum directed against the carboxy-terminus of neurotensin[10]. Incubation with the neurotensin antiserum (1 in 20 dilution) for 3 h not only prevented the action of neurotensin, but also inhibited the nerve stimulation-induced smooth muscle relaxation at all frequencies tested (Figs 3, 4). Higher dilutions of the antiserum at 1:50 and 1:100 were ineffective. Controls consisted of using the same dilution of either preimmune serum (Fig. 4) or an antiserum raised against [Lys^{8}Asn^9]neurotensin(8–13) a peptide sequenced from chicken small intestine which shares marked sequence homologies with neurotensin[11], but is not present in mammalian tissues[12]. This antiserum, which was raised in the same way as the neurotensin antiserum and had a similar antibody titre, did not cross-react with synthetic neurotensin. Neither the preimmune serum (Fig. 4) nor the antiserum raised against [Lys^{8}Asn^9] neurotensin(8–13) affected the smooth muscle relaxation produced by either neurotensin or inhibitory nerve stimulation.

It was possible that the effect of the neurotensin antiserum was due to a non-selective postsynaptic action on the circular smooth muscle. However, the antiserum did not affect the contractile response to 10 nM kassinin (Fig. 4), nor the reduction

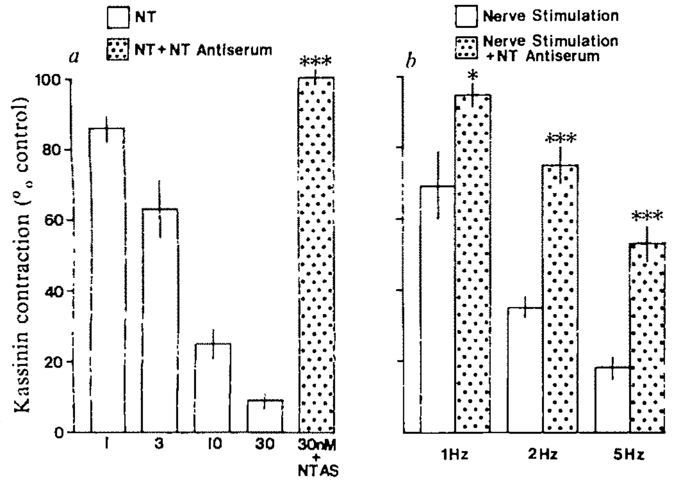

Fig. 3 Effect of neurotensin antiserum on the dose– and frequency–response curves to neurotensin (*a*) and non-adrenergic inhibitory nerve stimulation (*b*) in the guinea pig ileum circular smooth muscle. Note that the neurotensin antiserum completely reversed the inhibitory effect of neurotensin at all dose levels, with the effect on the maximum response of neurotensin (30 nM) shown above. The neurotensin antiserum also significantly antagonized the response to inhibitory nerve stimulation at all frequencies tested. All values have been expressed as a percentage of the control response to kassinin (100%). Open columns represent the controls and stippled columns the effects of neurotensin and inhibitory nerve stimulation in the presence of neurotensin antiserum. In each preparation, control responses were obtained before incubation of the tissues with the neurotensin antiserum (1:20 dilution) for 3 h at 37 °C. Each value represents the mean ± s.e.m. of 4–10 observations. * $P < 0.05$; *** $P < 0.001$ (Student's *t*-test).

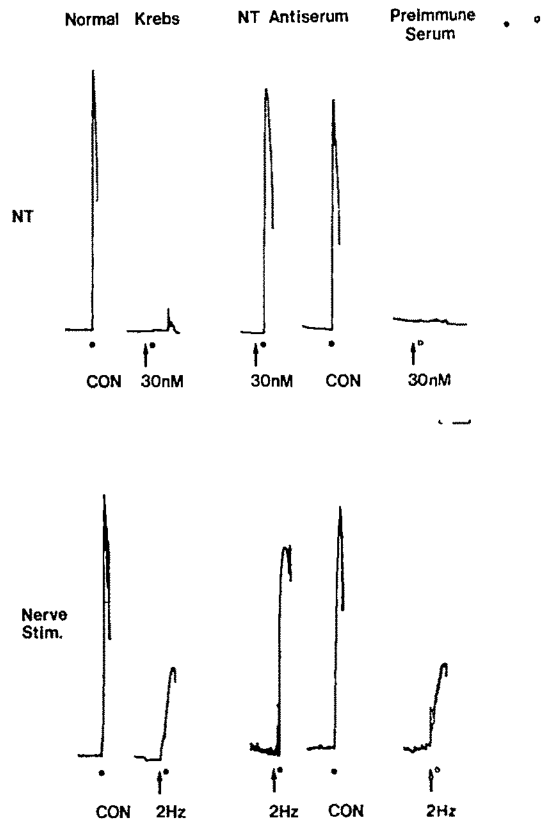

Fig. 4 Effect of neurotensin antiserum on the inhibitory responses of the guinea pig ileum circular smooth muscle to neurotensin and non-adrenergic inhibitory nerve stimulation. The upper row of records illustrates the effect of neurotensin (NT, 30 nM) and the lower row the effect of inhibitory nerve stimulation on the kassinin-induced tone of the guinea pig ileum circular smooth muscle preparation. Intramural nerve fibres were stimulated with 0.5-ms pulses at supramaximal voltage and at a frequency of 2 Hz. The first pair of responses are in normal Krebs and represent, respectively, a control dose of 10 nM kassinin (CON) followed by a subsequent dose in the presence of either NT or nerve stimulation. The second pair of responses are in the presence of the neurotensin antiserum (1:20 dilution) following prior incubation of the tissues with the antiserum for 3 h at 37 °C and the last response in each row shows the effect of prior incubation with preimmune serum (1:20 dilution) for 3 h at 37 °C. Time bar, 2 min. Note that the neurotensin antiserum completely antagonized the inhibitory effect of neurotensin and substantially reversed the effect of inhibitory nerve stimulation, whereas the preimmune serum had no effect on either parameter.

Methods: Male guinea pigs (250–400 g, Hartley strain) were stunned, the terminal ileum was dissected, flushed with Krebs saline at 37 °C and the circular smooth muscle preparation set up as previously described[9]. The tissues were suspended under a tension of 1 g in 2 ml organ baths containing Krebs saline at 37 °C and aerated with a mixture of 95% O_2 and 5% CO_2. The saline composition was (in mM): NaCl 118, KCl 4.7, $CaCl_2$ 2.5, $MgSO_4$ 1.2, $NaHCO_3$ 25, KH_2PO_4 1.2 and glucose 11. In all preparations tension was recorded with isotonic transducers. Contraction of the muscle tone was induced by 10 nM kassinin (CON) and all experiments were performed in the presence of atropine (5 μM), guanethidine (20 μM), indomethacin (1 μM) and mepyramine (5 μM). However, the contractile response to kassinin was found to be transient and hence inconvenient for the study of inhibitory responses in the conventional manner. The protocol of the present study was therefore similar to that of the anti-assay previously described by Burn[28]. Briefly, neurotensin was added (arrow) 20 s (optimal) before the addition of kassinin (●). Similarly, field stimulation of the inhibitory nerves was started (arrow) 20 s before the addition of kassinin (●) and was continued until the peak of the response to kassinin was reached, normally 25–30 s. The direct inhibitory effects of neurotensin and inhibitory nerve stimulation on the circular smooth muscle have therefore been observed as a reduction in the contractile response to kassinin.

Table 1 Relative potencies of neurotensin fragments in a binding and a biological assay

Peptide	Binding assay		Biological assay	
	IC_{50} (nM)	Potency (%)	IC_{50} (nM)	Potency (%)
NT(1–13)	3.2 ± 0.5	100	3.3 ± 0.3	100
NT(8–13)	7.3 ± 0.7	43	11.5 ± 0.8	29
NT(9–13)	633 ± 90	0.50	344 ± 75	0.95
NT(10–13)	>10,000	<0.04	>10,000	<0.04
NT(1–6)	>10,000	<0.04	>10,000	<0.04

The binding assay was the inhibition of specific ^{3}H-neurotensin binding to guinea pig ileum membranes and the biological assay the inhibition of kassinin-induced tone of the guinea pig ileum circular smooth muscle preparation. The binding of tritiated neurotensin (NT) was assayed at a concentration of 2 nM. The IC_{50} was defined as the concentration of unlabelled peptide required to inhibit the specific binding of ^{3}H-neurotensin by 50%. In the biological assay the IC_{50} was defined as the concentration of peptide required to produce 50% inhibition of the contractile response to 10 nM kassinin. The relative potencies were calculated by comparing the IC_{50} values with that of NT(1–13), taken as 100%. The results represent the means ± s.e.m. of between three and five separate experiments. The concentrations of NT(1–13) and of all NT fragments were determined by amino acid analysis. The purity of ^{3}H-NT was determined by subjecting an aliquot from each batch to reverse-phase HPLC[25]. NT(9–13) and NT(10–13) were synthesized by Dr B. J. Williams, NT(8–13) was purchased from Peninsula Laboratories and all other peptides were obtained from Cambridge Research Biochemicals.

($74.5 \pm 5.3\%$, $n = 4$) in this response which was produced by the β-adrenoceptor agonist isoprenaline (500 nM).

The present results indicate that neurotensin has a potent direct relaxant effect on the guinea pig ileum circular smooth muscle layer, where a dense accumulation of specific ^{3}H-neurotensin binding sites is found. The circular smooth muscle preparation may therefore constitute a favourable biological assay system for neurotensin. Electrophysiological studies have indicated that the circular smooth muscle layer of the guinea pig ileum is innervated by non-adrenergic, non-cholinergic inhibitory nerve fibres whose action is blocked by apamin[13,14]. In addition, it has been shown that ATP and vasoactive intestinal polypeptide are unlikely mediators of this inhibitory non-adrenergic effect[14]. In the present study, the relaxant effects of nerve stimulation and neurotensin were both apamin-sensitive; a similar effect has previously been noted for the relaxant effect of neurotensin in the guinea pig colon and the rabbit ileum longitudinal smooth muscle[15,16].

This parallelism suggested that neurotensin may be released from non-adrenergic inhibitory nerve fibres following nerve stimulation. In the absence of neurotensin receptor antagonists, we have made use of a specific neurotensin antiserum to neutralize the endogenous peptide. Specific antisera have been used to study the physiological function of hypothalamic releasing hormones[17–19]; more recently, both polyclonal and monoclonal antibodies have also been successfully used to prevent the actions of neuropeptides in both the peripheral and the central nervous system[20–24]. In the present study, the neurotensin antiserum inhibited the nerve stimulation-induced smooth muscle relaxation to a significant extent, whereas both the preimmune serum and a control immune serum were without effect. The residual smooth muscle relaxation observed after exposure to the neurotensin antiserum may be due to the inability of the antiserum to neutralize rapidly all of the neurotensin released; alternatively, a substance distinct from neurotensin may contribute to the relaxation of the circular smooth muscle. In conclusion, the present results are consistent with the hypothesis that neurotensin functions as an inhibitory non-adrenergic, non-cholinergic neurotransmitter in the guinea pig ileum.

We thank Dr P. C. Emson for the gift of the neurotensin antiserum, Dr S. P. Hunt for his advice and Mrs M. Wynn for help with the preparation of the manuscript.

Adenosine mediates a slow hyperpolarizing synaptic potential in autonomic neurones

T. Akasu, P. Shinnick-Gallagher & J. P. Gallagher

Department of Pharmacology and Toxicology, The University of Texas Medical Branch, Galveston, Texas 77550, USA

Considerable evidence has accumulated suggesting that purines, adenosine and ATP function as neurotransmitters in the central and peripheral nervous systems[1–4]. Burnstock[2] has proposed that purinergic receptors be classified into two types, P_1 and P_2, having adenosine and ATP, respectively, as agonist prototypes. Recent data suggest that ATP may mediate a synaptic potential in guinea pig vas deferens[5,6], but no such evidence exists for adenosine. The presence of a non-cholinergic, non-adrenergic nerve supply to the urinary bladder has been postulated[7,8] and termed purinergic[1,2], as these nerves have been shown to release ATP[7]. Furthermore, atropine-resistant contractions of bladder smooth muscle are thought to be mediated by ATP, while *in situ* experiments[9,10] in vesical parasympathetic ganglia have suggested that a purinergic modulatory mechanism may control urinary bladder function. We now report the presence of a slow hyperpolarizing synaptic potential (slow-h.s.p.) in neurones of cat vesical parasympathetic ganglia, produced by stimulating the preganglionic nerves, and provide evidence that the slow-h.s.p. is mediated by adenosine.

Vesical parasympathetic ganglia isolated from the surface of the urinary bladder were placed in a chamber superfused with oxygenated (95% O_2/5% CO_2) Krebs' solution of the following composition (mM): NaCl, 117; KCl, 4.7; $MgCl_2$, 1.2; $CaCl_2$, 2.54; NaH_2PO_4, 1.19; $NaHCO_3$, 25 and glucose, 11. We employed conventional intracellular recording methods using glass microelectrodes (50–80 MΩ) filled with 2 M K_2SO_4 (ref. 11).

Vesical parasympathetic ganglion cells were superfused with a solution containing hexamethonium (1 mM) to block nicotinic responses to synaptically released acetylcholine in all experiments[11]. Supramaximal stimulation (3–10 V) of the preganglionic nerve at 40 Hz for 250 ms in hexamethonium-containing solution revealed the presence of the slow-inhibitory postsynaptic potential (slow-i.p.s.p.), mediated through monosynaptic activation of muscarinic receptors[11] (Fig. 1*a*). When the stimulus

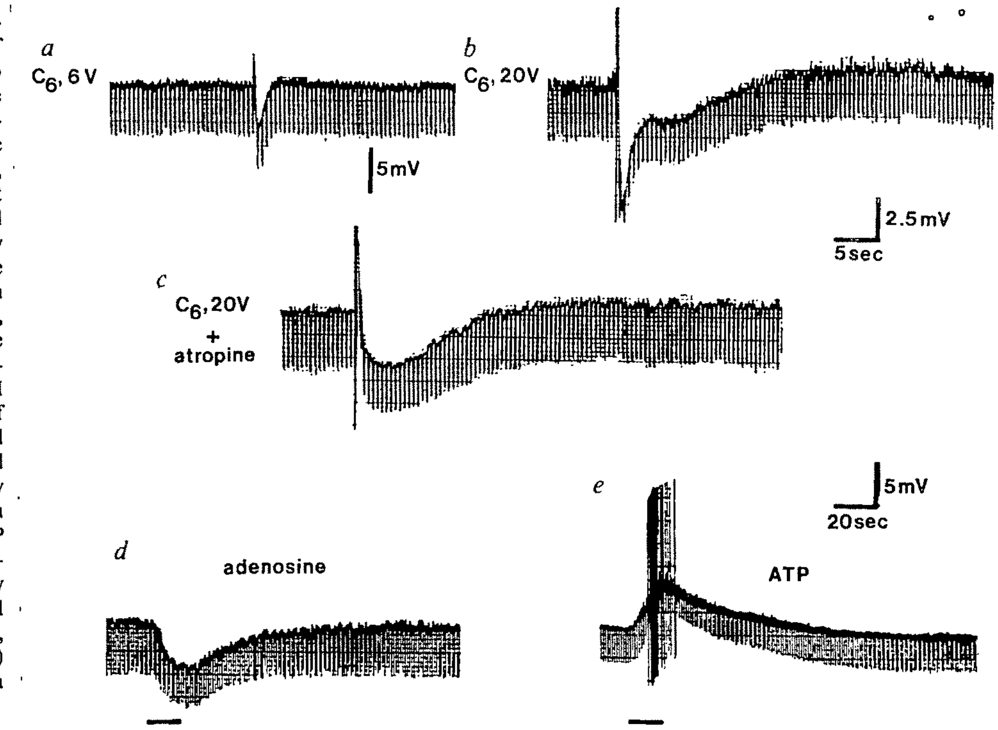

Fig. 1 Responses to nerve stimulation recorded in the presence of hexamethonium (C_6; 1 mM) and to exogenous application of adenosine (100 μM) and ATP (50 μM). *a*, Slow-i.p.s.p. elicited by preganglionic nerve stimulation (6 V, 40 Hz, 250 ms). *b*, Slow-i.p.s.p. recorded at a higher sensitivity in the same cell as in *a* after the stimulus intensity had been raised to 20 V; note the slower hyperpolarizing response on the falling phase of the slow-h.s.p. *c*, The slow-h.s.p., recorded from same cell as in *b*, remained after the slow-i.p.s.p. had been blocked with 1 μM atropine. Note that the sensitivity of the recording was increased in *b* and *c*. *d*, *e*, Adenosine (100 μM; *d*) and ATP (50 μM; *e*) were applied by superfusion as indicated. Action potentials recorded in the ATP response were truncated. The downward deflections were produced by injecting constant-current anodal pulses of 100 ms and 1.4 nA (*a*), 0.7 nA (*b*, *c*) and 0.5 nA (*d*, *e*) through the recording electrode as a measure of membrane resistance.

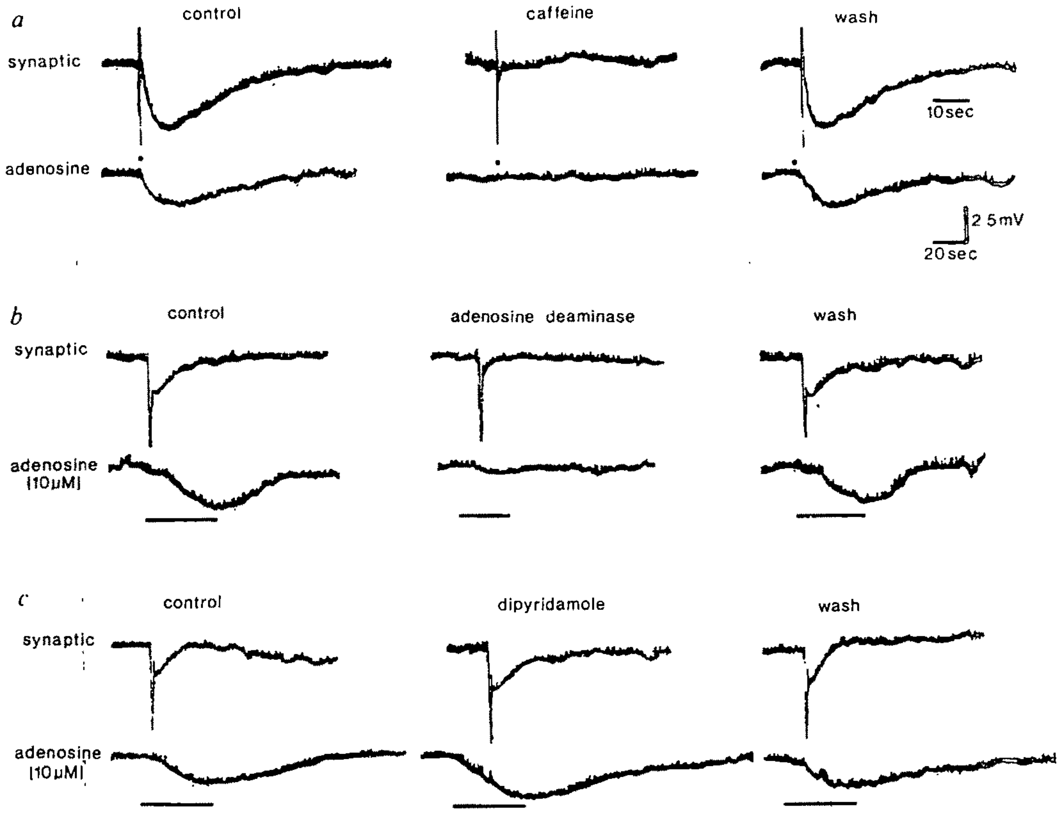

Fig. 2 Comparison of the pharmacology of the slow-h.s.p. and the adenosine hyperpolarization. *a*, The slow-h.s.p. and adenosine hyperpolarization in control conditions (left panels) and after 10 and 5 min treatment, respectively (middle panels), with 1 mM caffeine. The responses returned to control levels after a 15-min wash with normal Krebs' solution (right panels). Adenosine (100 μM) was applied to the bath in a drop from an 18-gauge needle attached to a 1-ml glass syringe as indicated (dot). Resting potentials were −66 mV and −62 mV, respectively. *b*, The slow-h.s.p. and adenosine hyperpolarization in control (left panels) and 10 min after treatment with 0.25 IU ml^{-1} adenosine deaminase (middle panels). The responses returned to control amplitude after 15 min washing with normal Krebs' solution (right panels). Resting potentials were −68 mV. Adenosine was applied by superfusion as indicated (bar). *c*, Slow-h.s.p. and adenosine response in control (left panels), 8 min after treatment with dipyridamole (1 μM; middle panels) and 10 min after washing with control Krebs' solution (right panels). Resting potentials were −59 mV and −60 mV, respectively.

intensity was increased (8–30 V), a slower hyperpolarizing potential appeared on the falling phase of the slow-i.p.s.p. (Fig. 1*b*). Treatment with atropine (0.5–1 μM) completely abolished the slow-i.p.s.p.[11] and revealed the presence of the slow-h.s.p. (Fig. 1*c*). This potential was quickly abolished in a low Ca^{2+} (0.25 mM), high Mg^{2+} (3.74 mM) solution, suggesting that the slow-h.s.p. was produced by a neurotransmitter released from the terminals of neurones whose axons were present in the preganglionic nerve trunk. The amplitude of the non-cholinergic slow-h.s.p. varied from 2 to 13 mV in individual neurones, with a mean amplitude obtained from 58 neurones of 4.1 ± 1.7 mV (mean ±s.d.), recorded at a mean resting membrane potential of 62.3 ± 3.4 mV. The mean duration of the slow-h.s.p. was 31.6 ± 5.5 s, an order of magnitude greater than that of the muscarinic slow-i.p.s.p.[11].

Adenosine (5 μM–1 mM) hyperpolarized (2–10 mV) most (92%) ganglion cells ($n = 71$, Fig. 1*d*); other neurones (8%) were slightly depolarized by or did not respond to adenosine. The adenosine hyperpolarization persisted in low Ca^{2+} (0.25 mM), high Mg^{2+} (3.74 mM) solution for more than 25 min,

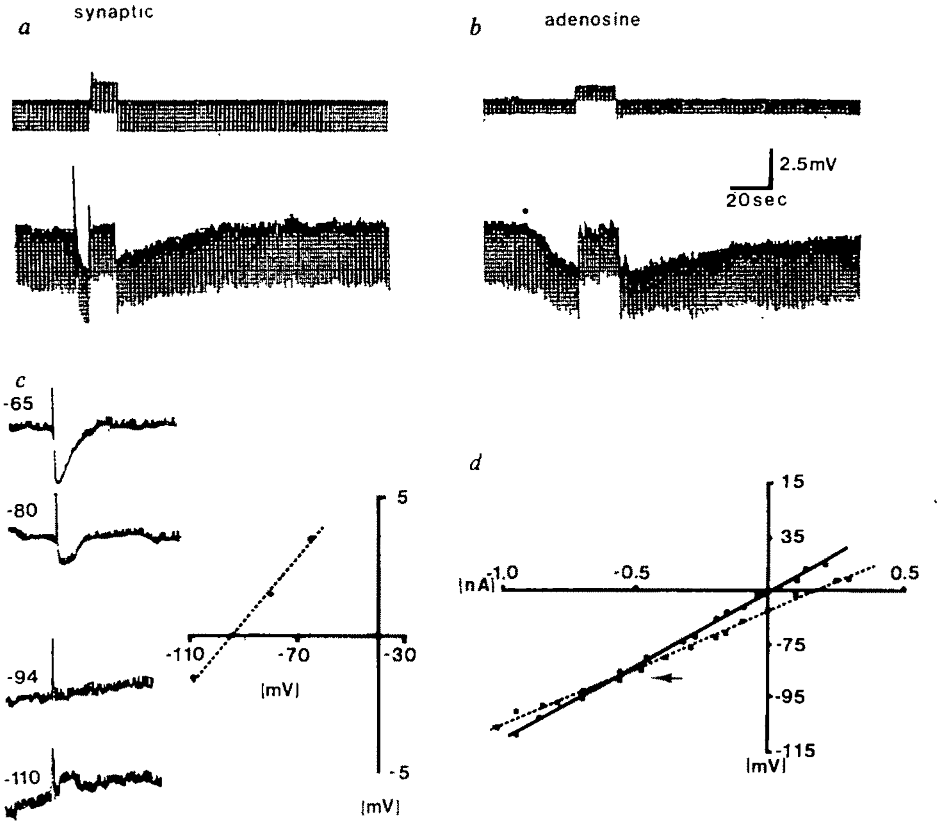

Fig. 3 Comparison of the membrane mechanism of the slow-h.s.p. and the adenosine hyperpolarization. *a*, *b*, Upper trace, the transmembrane current passed by means of a bridge circuit; lower trace, the membrane potential during the slow-h.s.p. (*a*) or during superfusion of adenosine (50 μM) applied in a drop to the organ bath as indicated (dot). Resting potential = −68 mV in *a* and −60 mV in *b*. *c*, Left panel, slow-h.s.p. recorded at different membrane potentials in the presence of hexamethonium (1 mM) and atropine (1 μM); right panel, graph of the relationship between the amplitude of the slow-h.s.p. (ordinate; 40 Hz, 250 ms) illustrated in left panels and membrane potential (abscissa). The slow-h.s.p. was nullified here, around −94 mV; the slow-h.s.p. reversed polarity with further hyperpolarization of the membrane. *d*, Hyperpolarizing and depolarizing current pulses of constant duration (100 ms) and varying amplitude were passed across the membrane in control solution (solid line; circles) and in the presence (dashed lines; squares) of a solution containing adenosine (50 μM). The difference in the slope of the lines indicates a decrease in resistance during adenosine superfusion. The intersection point of the lines (arrow) represents the estimated reversal potential of the response, here −90 mV for adenosine. Lines were fitted by eye.

suggesting a direct action of adenosine on vesical neurones. The adenosine hyperpolarization also persisted in the presence of hexamethonium (1 mM) and atropine (0.5–1 μM). On the other hand, bath application of ATP (100 nM–1 mM) produced a depolarization (3–12 mV) in 62% of vesical parasympathetic neurones tested ($n = 63$, Fig. 1*e*). Some parasympathetic neurones (14%) showed a hyperpolarizing response to ATP (100 nM–1 mM) application, while others (24%) were not affected by ATP at these concentrations. In many cases, ATP and adenosine were applied to the same cells. These data suggested that the response to exogenous adenosine application is similar to the slow hyperpolarizing synaptic response.

Pharmacological analyses were performed to examine the possibility that the slow-h.s.p. is mediated by a purinergic neurotransmitter[7,8]. Caffeine, known to be an antagonist of the P_1 purinoceptor[2], depressed the slow-h.s.p. recorded in 11 (73.3%) out of 15 neurones tested (Fig. 2*a*). The slow-h.s.p. was decreased 89.3 ± 7.7% ($n = 8$) by caffeine (1 mM) in 5 min and abolished in 10 min. The effect of caffeine was concentration dependent, 100 and 10 μM caffeine depressing the slow-h.s.p. by 64.4 ± 7.1% ($n = 7$) and 41.8 ± 5.2% ($n = 5$), respectively, after 5 min of treatment. In four neurones (26.7%), the slow-h.s.p. was relatively insensitive to the effect of caffeine (1 mM), being depressed by only ~22% after 10 min of treatment. Caffeine at these concentrations slightly hyperpolarized (1–3 mV) the membrane but did not significantly affect membrane resistance or directly evoked action potentials. Bath application of caffeine (1 mM) decreased the amplitude of the adenosine hyperpolarization by 92.6 ± 4.3% ($n = 11$) after 5 min of treatment. The adenosine hyperpolarization was subsequently blocked reversibly by caffeine (Fig. 2*a*), but the response to ATP was not affected (not shown). These data suggest that the receptor underlying the synaptic response is similar to that mediating the response to adenosine—a P_1 purinoceptor.

Adenosine deaminase, the enzyme which catabolizes adenosine to inosine and NH_3, depressed the amplitude of the slow-h.s.p. by 82.4 ± 8.6% (5 cells) after 5–10 min of treatment (Fig. 2*b*) and depressed the response to exogenous adenosine by 92.3 ± 7.4% ($n = 7$). Bath application of adenosine deaminase (0.25 IU ml^{-1}) produced no significant changes in the membrane potential or resistance. All the effects of this enzyme were reversible. The application of dipyridamole (3 μM), which has been reported to block the uptake of adenosine[12] and augment adenosine effects in heart muscle[13] and in neurones of sympathetic ganglia[14], produced a slight hyperpolarization of parasympathetic neurones (2–4 mV), with no appreciable change in membrane resistance. At 1 μM, dipyridamole increased the amplitude and duration of the slow-h.s.p. by 45.7 ± 5.3% ($n = 6$) and 185.1 ± 0.3% ($n = 6$), respectively (Fig. 2*c*), while the amplitude and duration of the response to exogenous adenosine were enhanced by 128.3 ± 10.3% ($n = 6$) and 136.6 ± 15.4% ($n = 6$), respectively. These data suggest that the synaptic response, the slow-h.s.p., and adenosine hyperpolarization are affected by pharmacological agents in a similar manner.

We compared the membrane mechanism of the slow-h.s.p. with that of the adenosine hyperpolarization (Fig. 3). The slow-h.s.p. was associated with a decrease in membrane resistance (Fig. 3*a*). The changes in membrane resistance could be separated from membrane rectification by passing a cathodal current through the recording electrodes and returning the membrane to its original resting level during the peak of the slow-h.s.p. or adenosine hyperpolarization. The mean decrease in resistance during the slow-h.s.p. was 35.8 ± 8.8% ($n = 12$). Adenosine (100 μM) induced hyperpolarization was also associated with a decrease in membrane resistance (Fig. 3*b*), to 33.7 ± 5.6% ($n = 9$) of that at original resting potential levels. We also compared the reversal potential for the synaptic response with that of the adenosine hyperpolarization. The amplitude of the slow-h.s.p. was decreased by membrane hyperpolarization and eventually reversed in polarity at a membrane potential of −95 mV (Fig. 3*c*). The mean reversal potential of the slow-h.s.p. obtained in five neurones was −93.7 ± 7.4 mV. As Fig. 3*d* shows, the slope of the current-voltage (*I*–*V*) curve was decreased in the presence of adenosine (100 μM). The reversal potential of the adenosine hyperpolarization estimated by the intersection of *I*–*V* curves determined in control and adenosine (50 μM) containing Krebs' solution[15] was −90 mV; the mean reversal potential of the adenosine hyperpolarization obtained from nine neurones was

−93.5 ± 4.3 mV. The amplitude of the adenosine hyperpolarization was increased in K^+-free solution to 175.5 ± 10.3% of the control response ($n = 9$). The slow-h.s.p. was also augmented in a low-K^+ (0.5 mM) solution, to 156.1 ± 8.1% of the control value ($n = 7$). Neither the slow-h.s.p. nor the adenosine hyperpolarization was affected by prolonged injection of Cl^- ion, applied by passage of outward current through an electrode filled with 2 M KCl. This indicates that Cl^- ions are probably not involved in the responses. These data suggest that both the slow-h.s.p. and the adenosine hyperpolarization are mediated primarily through activation of a K^+ conductance. A similar ionic mechanism for a purinergic hyperpolarization has been reported in guinea pig taenia coli[16], frog heart muscle[13] and *Xenopus* oocyte[17].

Our data demonstrate that a synaptic response, a slow-h.s.p., produced by preganglionic nerve stimulation in vesical parasympathetic neurones in the presence of cholinergic blocking agents, can be most closely mimicked by exogenous application of adenosine. The present results seem to satisfy the pharmacological and electrophysiological criteria for establishing adenosine as a neurotransmitter in vesical parasympathetic ganglia. These data provide the first evidence for a synaptic response mediated by adenosine and lend further support to the mounting evidence that purines function as neurotransmitters in the autonomic nervous system.

We thank Drs Gil Hillman, Betty Williams and James Blankenship for their careful review of the manuscript. This work was supported by NS 16228, to P.S.G.

University of Washington, Seattle, Washington 98195, USA

The dwarf little (*lit*) mouse is a model for the human hereditary disorder, isolated growth hormone (GH) deficiency type I[1]. In these animals, dwarfism results from an autosomal recessively inherited gene mutation. The *GH* gene is present[2] but production of *GH* mRNA is deficient[3], resulting in reduced serum GH and concomitantly decreased serum somatomedin[4–6]. Growth retardation is evident by 15 days of age and adult animals reach approximately one-half normal size[1]. Mutant mice of both sexes also exhibit a delayed onset of puberty, with males having a high degree of infertility[1]. As administration of GH restores growth[7], we reasoned that growth failure in the mutant mice might be corrected by providing them with sufficient GH by gene therapy. Here we demonstrate that although the rat and human *GH* genes alone do not restore growth in transgenic mutants, a metallothionein–rat growth hormone fusion gene (*MT–rGH*) does. Moreover, the fertility of transgenic mutant males is improved; however, female fertility is impaired.

As one approach to gene therapy, we tested the feasibility of introducing either rat or human *GH* genes that contained normal 5′ and 3′-flanking sequences[8,9]. Because mutant eggs are difficult to obtain, we piloted this approach with normal mice. Thirty-two transgenic mice carrying one or more copies of the foreign *GH* genes were produced, and despite low levels of human growth hormone (*hGH*) mRNA transcripts in the liver and pituitary of some mice carrying the hGH_N and *cGH4* genes (data not shown), no foreign GH was detectable and none of the mice grew larger than normal (Table 1). This lack of *hGH* gene expression has occurred in other *hGH* mice[10] and may reflect a requirement for precise chromosomal localization[11,12], insufficient flanking sequences or highly species-specific regulation of *GH* gene expression. The absence of detectable serum hGH and increased growth suggested that introducing normal *GH* genes into mutant eggs would be ineffective; therefore, we attempted to correct the growth disorder of mutant *lit*/*lit* animals by introducing a *MT–rGH* fusion gene into mutant eggs, as this construct has been shown to stimulate growth of normal mice[13]. Forty-one animals developed from microinjected eggs; seven *lit*/*lit* mice carried the foreign gene (Table 2).

By 5 weeks of age, six of the seven transgenic *lit*/*lit* mice were already twice mutant size, and by 16 weeks were approximately 1.5 times the size of *lit*/+ mice (Table 2). Thus *MT–rGH*

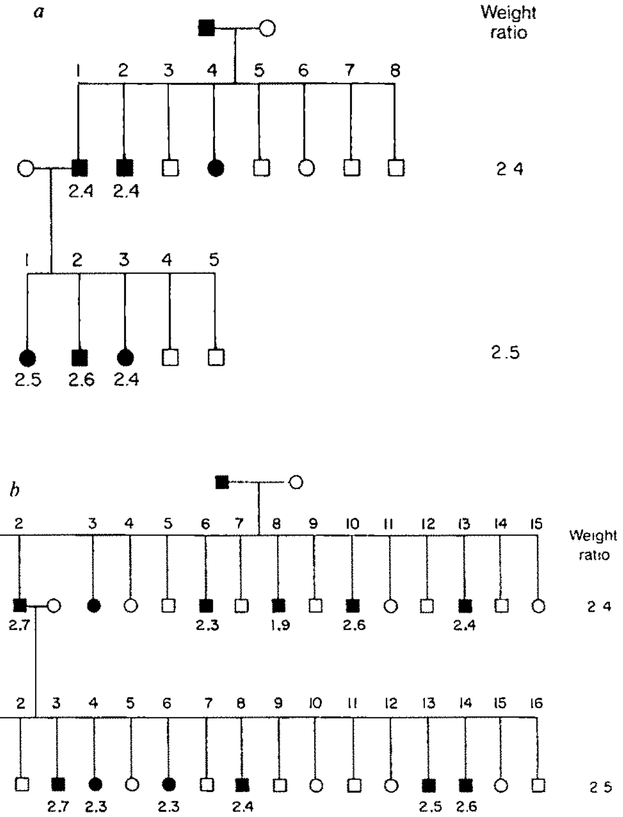

Fig. 1 Pedigree from: *a*, 41-1; *b*, 54-1 males. Mice that carry the *MT–rGH* genes are indicated by the solid symbols. Squares represent males and circles females. Numbers above symbols designate animal number and numbers below solid symbols the weight ratio of a MT-rGH mouse to control littermates at 6 weeks of age. Female 3 in the F_1 generation of 54-1 and female 4 in the F_1 generation of 41-1 died before body weights were taken.

Table 1 Transfer of *GH* structural genes to mice

Injected genes	DNA length (kb)	No. of transgenic mice	No. of gene copies	Rat or human GH in serum	Body weight ♂	Body weight ♀
rGH	7.6	8	1–250	ND	27.4 ± 2.1	22.3 ± 1.8
hGH_N	2.6	8	1–10	ND	27.1 ± 2.3	22.7 ± 1.1
hGH_N, hPL_L, hPL_A	43.0	16	1–50	ND	27.6 ± 1.2	21.5 ± 1.5
Control	—	—	—	—	27.5 ± 3.2	22.2 ± 1.7

A 7.6-kilobase (kb) *Bam*HI linearized fragment containing the entire *rGH* structural gene[8,19] was isolated and about 1,000 copies were microinjected into the male pronucleus of eggs from C57 × SJL hybrid crosses[20]. The 2.6-kb *Eco*RI linearized fragment containing the entire hGH structural gene (hGN_N)[9,21] or a cosmid fragment containing three genes of the *hGH* gene family (hGN_N and two human placental lactogen genes, hPL_L and hPL_A; *cGH4*, 43 kb)[21] were isolated and about 1,000 copies microinjected. The number of foreign structural genes per cell was estimated by DNA dot hybridization with a nick-translated 1.0-kb *Pst*I probe for *rGH* and a 1.0-kb *Pvu*II probe for hGH_N and *cGH4*. The radioactivity was then measured by scintillation counting[11,13]. Serum rat GH or hGH were determined by radioimmunoassay of duplicate samples using either rat[19] or human[11] GH standards respectively. The GH antiserum used interacts with both rat and mouse GH; therefore 'ND' indicates no significant difference between the serum GH concentration of rGH transgenic (mean ± s.d. 254 ± 54) and control (319 ± 50) mice. The concentration of hGH in hGH_N and cGH4 mice was lower than the limit of detection (~10 ng ml^{-1}) and is listed as 'ND'. Body weight is given as mean ± s.d. at 11 weeks of age; $n = 42$ animals.

Table 2 Expression of *MT–rGH* fusion gene in transgenic *little* mice

Animal	Sex	Genotype	Gene copy (No. per cell)	Serum GH (ng ml^{-1})	Body weight (g)	Ratio
20-1	♀	*lit/lit*^{1}	4	2,600	50.0	4.0
41-1	♂	*lit/lit*^{2}	17	31,200	41.8	2.9
41-2	♀	*lit/lit*^{2}	98	29,300	38.0	3.0
41-3	♀	*lit/lit*^{2}	1	1,463	12.9	1.0
54-1	♂	*lit/lit*^{1}	8	2,764	43.7	3.0
65-1	♀	*lit/lit*^{1}	10	1,630	39.0	3.1
65-2	♀	*lit/lit*^{1}	12	6,540	37.5	3.0
Control	♂	*lit/lit*	—	66 ± 11	14.6 ± 1.8	
Control	♀	*lit/lit*	—	76 ± 8	12.6 ± 0.4

Control	♂	*+/+*	—	110 ± 18	31.0 ± 0.7	
Control	♀	*+/+*	—	240 ± 55	25.9 ± 1.0	

A 5.0-kb linear fragment of the fusion gene *MT–rGH*[13] containing the mouse *MT-I* regulator/promoter region fused to *rGH* gene was injected into fertilized one-cell eggs collected from superovulated[22] *lit/lit* females crossed with either *lit/lit* males or hypodactyl males carrying the little gene (*Hd+/+lit*). The male pronuclei of 690 fertilized eggs were microinjected with approximately 2 pl of buffer containing 300–600 copies of DNA, and 494 eggs were transferred into the oviducts of pseudopregnant recipients[20]. The animals were weaned and total nucleic acids extracted from a piece of tail and used for dot hybridization with a probe corresponding to exons 1 and 2 of *rGH* gene. Digestion of the DNA by *Sst*I or *Stu*I and Southern blotting confirmed the presence of *MT–rGH* genes and indicated that, in all animals with multiple copies, the foreign genes were integrated as tandem arrays (data not shown)[20]. For the genotype, mice that developed from eggs obtained from the cross mutant *lit/lit* females × *lit/lit* males are indicated by superscript 1 and those developing from crosses between *lit/lit* females and *Hd+/+lit* males (hypodactyl males carrying the little gene) are indicated by superscript 2. Mutant males have delayed sexual maturation and show a marked degree of infertility[1]. This suboptimal fertility was improved by implanting pituitaries from heterozygous mice into mutant males, thereby allowing us to make homozygous crosses for egg collection. The hypodactyl gene which is closely linked to *little* gene locus[1] was introduced into the little colony by crossing *lit/lit* females with *Hd+/++* males and using the resulting hypodactyl male offspring (*Hd+/+lit*) for stud with *lit/lit* females. Mice resulting from this cross are either *+lit/+lit* (five-toed and dwarf) or *Hd+/+lit* (hypodactyl and normal). The number of *MT–rGH* genes per cell was estimated by DNA dot hybridization with a nick-translated *Sst*I–*Bgl*II probe corresponding to the mouse *MT-I* promoter/regulator, and scintillation counting[23]. Serum GH levels were determined by radioimmunoassay of duplicate samples using GH standards[19]. The antibody used for rGH determinations binds both rat and mouse GH; therefore appropriate control values should be subtracted from transgenic GH values. Body weights were compared at 16 weeks of age. The weight ratio compares transgenic mutant body weight to control mutant mice of the same sex. Values for controls are mean ± s.e.m., with $n \geq 8$ in each group.

expression in transgenic mutants not only restores growth but changes their phenotype from dwarfs to giants. The absence of a correlation between copy number or gene dosage and growth rate has also been observed in other *MT–rGH* mice (unpublished) and *MT–hGH* mice[11] and may result, at least in part, from only one or a few genes in the tandem arrays actually being expressed.

Serum GH levels in *MT–rGH* transgenic and control mice were quantified to see whether the accelerated growth correlated with elevated serum GH (Table 2). Mutant mice had approximately one-third the quantity of GH found in *lit/+* mice. All seven of the transgenic mutant mice had elevated serum GH ranging between 20 and 400 times greater than *lit/lit* control mice and 5 and 120 times greater than *lit/+* and *+/+* controls. The one transgenic mouse which failed to grow also had elevated serum GH. Transgenic mice with this characteristic have occurred previously in both *MT–rGH* (unpublished) and *MT–hGH*[11] experiments, indicating that although an immunoreactive product is produced, its biological potency is not assured.

To determine whether *MT–rGH* was stably integrated into the host chromosome making the phenotype heritable, two transgenic *lit/lit* males, 41-1 and 54-1 (Table 2), were bred with *lit/lit* females (Fig. 1). Both males transmitted their characteristic number of copies of fusion gene (data not shown) to approximately half of their offspring, indicating that multiple copies were integrated into a single chromosomal location. In both lines, the fusion gene has been transmitted into the second generation as well; every animal carrying *MT–rGH* genes was more than twice mutant size by 6 weeks of age.

To establish when transgenic mutants develop a sensitivity to elevated serum GH, we bred 54-1-2 ♂ with *lit/lit* females (Fig. 1) and compared the growth rates of transgenic and normal mutant offspring and *+/+* controls (Fig. 2). At about 40 days of age the growth of mutant mice essentially ceases. In contrast, transgenic mutant mice enter an accelerated growth phase at about 20 days of age and by 90 days they are approximately three times the size of nontransgenic littermates. Transgenic mutants surpass normal body weight by 30 days of age and by 90 days are more than 1.5 times normal weight.

All the transgenic males in the F_1 generation of 54-1 have been bred and have sired at least two litters. Thus in contrast to mutant males where only 50% sire one litter, 30% sire second litters and third litters are rare; the fertility of transgenic mutant males is improved by *MT–rGH* expression. Transgenic mutant females (with the exception of 41-3, Table 2) were also bred to *+/+* males and all four were infertile. Although control *lit/lit* females show delayed sexual maturation, they eventually reach full fertility[1]. We also assessed the effects of extra-pituitary GH production on the fertility of *MT–GH* transgenic C57 × SJL hybrid mice. F_0 males exhibited slightly reduced fertility (15 out of 20 were fertile). The fertility of F_1 *MT–GH* male mice was

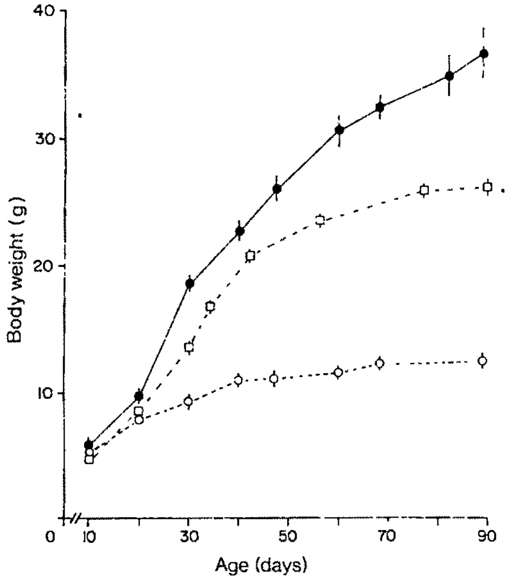

Fig. 2 Growth curves of MT–rGH *lit/lit* mice, nontransgenic littermates and control C57Bl/6J mice. One litter (eight pups) from the F_2 generation of 54-1 (see Fig. 1) was marked 1 week after birth and their weights were recorded periodically. Hybridization of tail DNA with a 0.38-kb *Xho*I–*Pvu*II *rGH* probe revealed five offspring inherited the *MT–rGH* gene (●) and three did not (○). □, Weights of C57Bl/6J mice. Mean body weights ± s.e.m. are indicated at each point.

normal with 11 out of 12 siring multiple litters. In contrast, the fecundity of F_0 transgenic females was dramatically reduced: only 1 of 10 of the *MT–GH* females bred was fertile. Thus whereas excess GH in transgenic mutant males improves fertility and has a negligible effect on the fertility of other *MT–GH* males, it dramatically reduces the fertility of both transgenic mutant and +/+ females. The mechanisms by which GH influences fertility are unexplored.

Several different *Drosophila* null mutants have been corrected recently by introducing wild-type gene counterparts into the germ line by their injection as part of P-element vectors into mutant eggs[14–16]. In the case described here, the primary defect is unknown. The *lit* mutation probably affects the regulation of expression of *GH* gene rather than gene itself[2,3]. Therefore, we attempted to correct the phenotypic defect in GH production by supplying a *GH* gene attached to an alternate promoter so that it would be independent of normal *GH* regulation. Although this approach has remedied the diminutive size of *lit/lit* mice as well as improved the fertility of males, we have uncovered an unsuspected deleterious effect of chronic elevated GH production on female fertility.

Although it seems feasible to correct certain genetic defects in animals, the application of the present technology to humans is inappropriate for several practical reasons. First, the techniques are inefficient; only about 1% of the injected eggs develop into mice that express the gene. Second, because the integration site of the foreign DNA is unpredictable, it is not possible to replace mutant DNA sequences with normal sequences. Thus the mutant gene will not be eliminated from the gene pool and will probably segregate independently of the foreign gene in the next generation. Furthermore, the unpredictability of integration means that it is possible that the foreign DNA could disrupt a normal gene, thereby creating a new mutation[10,17,18]. Current estimates are that about 20% of transgenic mice harbour recessive mutations[10,17]. These considerations, coupled with the fact that for most genetic diseases only one of four offspring are at risk, argue against application to humans.

We thank Dr Ronald Evans for continued interest and help, Myrna Trumbauer and Mary Yagle for experimental assistance, Dr Eva Eicher and Linda Washburn for assistance in setting up our *little* and *hypodactyl* colonies, and April Hamel for secretarial help. The cosmid containing the human *GH* gene family was provided by Greg Barsh and Richard Gelinas. R.E.H. was supported by NIH training grant HD 07155, and the work by research grants from NIH (HD 17321 and HD 09172) and NSF (PCM 81 07172).

Live recombinant vaccinia virus protects chimpanzees against hepatitis B

Bernard Moss*, Geoffrey L. Smith*, John L. Gerin† & Robert H. Purcell‡

* Laboratory of Viral Diseases, and ‡ Laboratory of Infectious Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, Maryland 20205, USA

Hepatitis B virus (HBV) is an important human pathogen responsible for over 200 million cases of chronic infection, many of which progress to hepatocellular carcinoma. Although HBV cannot be propagated in tissue culture, highly effective subunit vaccines obtained from the plasma of chronically infected patients have been developed and licensed[1–3]. Such vaccines are safe but their expense and limited quantities make them unavailable to most Third World countries. Other approaches to vaccine construction, including purification of the HBV surface antigen (HBsAg) from genetically engineered eukaryotic cells[4–13] and the synthesis of peptides predicted from the nucleotide sequence of the HBsAg gene[14–19], are still under evaluation. Another potential application of recombinant DNA technology to vaccine development is the use of live virus vectors to express foreign genes[20–25]. An infectious vaccinia virus recombinant that expressed the HBsAg in animal cells and which stimulated the production of antibody to HBsAg (anti-HBs) in rabbits represented a novel candidate vaccine of this class[22,23]. As a continuation of our earlier study, we now present evidence that chimpanzees vaccinated with a live recombinant vaccinia virus were protected against hepatitis following challenge with HBV.

The construction of vHBs4, the recombinant vaccinia virus used for these experiments, has been described elsewhere[22]. Briefly, a 1,350-base pair DNA fragment of HBV strain *adw*, containing the entire gene coding for HBsAg, was fused to an early vaccinia virus promoter and inserted into the coding sequence of the vaccinia virus thymidine kinase (*tk*) gene. The chimaeric gene was inserted into vaccinia virus by homologous recombination *in vivo* and infectious TK^- recombinant virus was isolated.

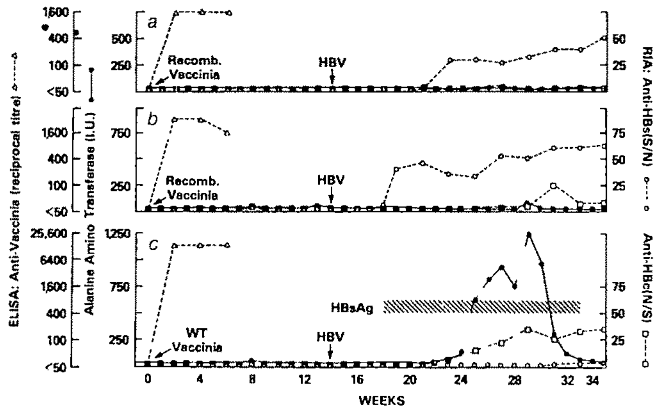

Fig. 1 Response of chimpanzees to intradermal vaccination with live recombianant virus vHBs4 or wild-type vaccinia virus, followed by challenge with live HBV. Chimpanzee 66 (*a*) and chimpanzee 67 (*b*) received recombinant vaccinia virus; chimpanzee A-98 (*c*) received wild-type vaccinia virus. Alanine aminotransferase activity is expressed in IU l^{-1}. Antibodies to vaccinia are expressed as reciprocal dilutions; anti-HBs and anti-HBc are expressed as the ratio of sample c.p.m. to negative control c.p.m. (S/N) and negative control c.p.m. to sample c.p.m. (N/S) respectively. Positive HBsAg values (>2.1 P/N) are shown as cross-hatching; between weeks 19 and 32, chimpanzee A-98 had P/N values ranging from 56 to 155.

Three chimpanzees (*Pan troglodytes*) weighing 14–25 kg were housed and maintained as described previously[26]. None showed serological evidence of prior exposure to HBV, as determined with commercial radioimmunoassays for HBV markers (HBsAg, AUSRIA; anti-HBs, AUSAB; anti-HB core antigen, anti-HBc, CORAB; anti-HBc IgM, CORZYME-M, Abbott Laboratories). Also, the animals had no other evidence of hepatitis, as judged by normal levels of alanine aminotransferase, aspartate aminotransferase and isocitric dehydrogenase enzymes.

To test the ability of vaccinia virus recombinant vHBs4 to protect chimpanzees against hepatitis, 10^8 plaque forming units (PFU) in 0.1 ml were administered intradermally in the upper back of two animals (66 and 67). A third chimpanzee (A-98) was vaccinated with 10^8 PFU of wild-type vaccinia virus. All three chimpanzees developed primary vaccinia lesions at the sites of vaccination. The two chimpanzees vaccinated with the recombinant virus had dermal lesions of diameters 24 and 22 mm, respectively. The chimpanzee vaccinated with the wild-type vaccinia developed a larger primary lesion of 37 mm diameter. A secondary vaccinia lesion developed in the right axilla of this animal. The greater severity of infection in the chimpanzee receiving wild-type virus, compared with that of chimpanzees receiving recombinant virus, was also reflected in a four- to eight-fold higher antibody titre to vaccinia virus when tested by enzyme-linked immunosorbent assay (ELISA)[27] (Fig. 1). Correlation of the TK^- phenotype of recombinant vaccinia virus with attenuated pathogenecity will be presented elsewhere.

Following vaccination, weekly serum samples were obtained from the three chimpanzees and tested for biochemical evidence of liver disease and serological evidence of exposure to hepatitis B viral antigens as described above. All sera were negative for elevations of liver enzyme activity and for evidence of exposure to HBV antigen except for one weak positive but repeatable 2.5 P/N value (ratio of positive c.p.m. to negative control c.p.m.) for anti-HBs 8 weeks after vaccination of chimpanzee 67 (Fig. 1).

Fourteen weeks after vaccination, all three animals were challenged intravenously with $10^{3.5}$ chimpanzee ID_{50} units of live HBV (subtype *ayw*, strain MS-2), a dose and strain of HBV which has consistently produced hepatitis B in chimpanzees[26,28]. Figure 1 shows that chimpanzee A-98 (vaccinated with wild-type vaccinia) developed typical hepatitis B. Circulating HBsAg appeared 4 weeks after HBV challenge and reached a peak P/N value of 155. Anti-HBc and biochemical evidence of hepatitis occurred after 8 and 9 weeks, respectively. HBsAg levels declined and disappeared by 19 weeks after challenge, coincident with the appearance of anti-HBs.

In contrast, chimpanzees 66 and 67 (vaccinated with recombinant virus) had no detectable HBsAg or biochemical evidence of hepatitis. Instead, anti-HBs appeared at 4–7 weeks after challenge and rapidly rose to high levels that persisted throughout the experiment. Both chimpanzees developed low levels (3.8–8.8 N/P) of anti-HBc, 21 or 27 weeks post-challenge, indicating that they had experienced inapparent infections with HBV. As a follow-up, the livers of the two chimpanzees inoculated with recombinant vaccinia virus were biopsied at 11 months after HBV challenge. There was no evidence of acute or chronic hepatitis.

Sera from chimpanzees 66 and 67 were analysed for the immunoglobulin class of anti-HBs by sucrose gradient centrifugation followed by radioimmunoassay of the fractions containing IgM or IgG immunoglobulins for anti-HBs activity. Two weeks after detection of anti-HBs in chimpanzees 66 and 67, IgM and IgG anti-HBs activities were present in approximately equal proportions (data not shown). Late convalescent sera (14–17 weeks after seroconversion) contained only IgG anti-HBs. Thus, the immune reaction had features characteristic of both primary and anamnestic responses. Sera obtained from chimpanzees 66 and 67 during the early phase of the immune response (2–6 weeks after seroconversion) were tested by radioimmunoassay[29] for the subtype specificity of the anti-HBs: only anti-*a* was detected.

This study demonstrated that chimpanzees receiving a single intradermal vaccination with a live recombinant vaccinia virus that expresses HBsAg were protected against hepatitis B. Following a challenge with HBV of a heterologous subtype, the vaccinated animals experienced a mild inapparent infection characterized only by seroconversion to anti-HBs and anti-HBc. The marginal primary antibody response of chimpanzees 66 and 67, when compared with the anti-HBs response of rabbits following vaccination with this same recombinant vaccinia virus, is in keeping with the relatively poor response of primates to a single dose of HBsAg in the absence of adjuvants[30]. Although the chimpanzees had little or no circulating anti-HBs after vaccination, they were immunologically 'primed'. Consequently, they showed a brisk and sustained antibody response, presumably due to newly synthesized HBsAg, following challenge with live HBV. The early detection of IgG anti-HBs and the anti-*a* subtype specificity are consistent with the anamnestic nature of the response. Priming of neutralizing antibody production by vaccination of rabbits with synthetic peptides of poliovirus structural protein VP1 has been reported[31], but has not been demonstrated previously for HBV.

In conclusion, these studies indicate the feasibility of using a recombinant vaccinia virus as a live hepatitis B vaccine. Current research is directed towards increasing HBsAg expression by using stronger vaccinia virus promoters.

Since submission of this manuscript, additional vaccinia virus recombinants that express prokaryotic chloramphenicol acetyltransferase[32], herpesvirus glycoprotein D (ref. 33), HBsAg[33] and malaria sporozoite antigen[34] have been described.

We thank R. L. M. Buller for vaccinia virus antibody determinations, H. Popper for evaluation of liver biopsies, W. T. London and J. Cicmanec for care and management of the chimpanzees and R. Engel for technical assistance.

Defect in the generation of light-chain diversity in bursectomized chickens

Sirpa Jalkanen*‡, Markku Jalkanen†‡, Kaisa Granfors* & Paavo Toivanen*

* Departments of Medical Microbiology and †Medical Chemistry, Turku University, SF-20520 Turku, Finland

The avian bursa of Fabricius has been regarded as a central organ for B-cell development[1,2], but there is controversy about the existence of other sites for differentiation of B cells[3–6]. We have recently shown that chickens surgically bursectomized as early embryos, before the bursal primordium appears, can produce cytoplasmic, surface and serum immunoglobulins of IgM, IgG and IgA classes but are unable to generate specific antibodies in response to antigen[7–9]. We have therefore examined the structure and diversity of immunoglobulins of bursectomized chickens. Analysis of serum IgG revealed normal γ-heavy chains but altered light chains with more basic and less diverse isoelectric points than normal. These light chains may represent germ-line specificities not diversified by somatic mutations. Thus the bursa of Fabricius appears not to be necessary for the production of immunoglobulin molecules as such but to function in the creation and expansion of the antibody repertoire, possibly by providing a microenvironment for somatic mutations.

Chickens were surgically bursectomized after 60 h incubation by cutting off the tail caudally to the leg buds. Bursectomy was ascertained by careful microscopic examination at the autopsy at 10 weeks of age[7,8]. All bursectomized chickens had detectable amounts of serum immunoglobulins; mean concentrations of serum IgM and IgA were normal, whereas that of serum IgG was 1/10 of the control value[9]. In spite of immunoglobulin production, the bursectomized chickens did not respond to repeated immunizations with levan, *Escherichia coli* lipopolysaccharide, tetanus toxoid, dinitrophenyl-bovine serum albumin, brucella, diphtheria, pertussis, salmonella, sheep red blood cells and human γ-globulin[7,9]. Also all the tests made to detect natural antibodies to major histocompatibility complex (MHC) products, rabbit red blood cells, faecal bacteria and phosphorylcholine, and autoantibodies to the kidney, thyroids and liver, were totally negative. Antibodies to bursal structures were not observed[9]. The total lack of inducible or spontaneous antigen-specific antibody responses, given near normal immunoglobulin levels, suggested that the immunoglobulins produced by bursectomized chickens might be abnormal in structure. To examine this possibility, we compared serum IgG of the bursectomized and control chickens at the age of 10 weeks. Serum proteins were electrophoresed in SDS-polyacrylamide gel electrophoresis (PAGE)[10] or electrofocused in thin layer agarose gel[11], and then

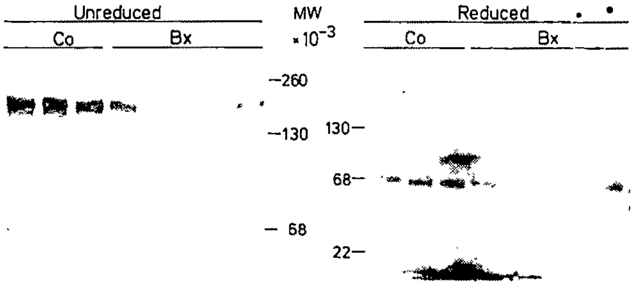

Fig. 1 Molecular weight of serum IgG and γ-chain of the control (Co) and bursectomized (Bx) chickens. Serum samples (1 µl) were examined in non-reducing (left) or reducing (right) conditions by SDS–PAGE[10] by using a 5% homogeneous or 5–22.5% gradient gel, respectively. After electrophoresis, proteins were transferred to a nitrocellulose sheet[12] (HAWP 000 10; Millipore). The sheet was saturated for 1 h with 20% fetal calf serum (FCS) diluted in Tris-buffered 0.9% NaCl (TBS) and then incubated for 2 h with rabbit antiserum against chicken γ-chain[8] diluted in 20% FCS–TBS. After extensive washings with 0.1% Triton-X-100-TBS for 1 h, alkaline phosphatase conjugated pig anti-rabbit IgG (Orion Diagnostica) was added and incubation was continued overnight. After washings with 0.1% Triton-X-100–TBS phosphatase activity on the sheet was visualized with α-naphthyl phosphate as a substrate and 4-amino-diphenylamine diazonium sulphate as a staining dye[11]. Pepsin-digested collagen β- and α-chains of type I of molecular weight (MW) 260,000 (260K) and 135K, bovine serum albumin (68K) and trypsin inhibitor (22K) were used as molecular weight standards.

Fig. 2 γ-Chain fragments of one control (Co) and one bursectomized (Bx) bird after enzymatic digestion with *Staphylococcus aureus* V-8 protease (V-8), chymotrypsin (CH) or trypsin (T): control incubation without any enzyme (C). Sodium sulphate precipitated serum immunoglobulins in SDS-buffer were subjected to enzymatic digestion for 2 h at 37 °C according to Cleveland *et al.*[21] All enzymes were used in concentrations of 25 µg ml⁻¹. After digestion proteins were fractionated by using a 15% homogeneous SDS–PAGE. Transfer to a nitrocellulose sheet and identification of γ-chain fragments were performed as described in Fig. 1 legend.

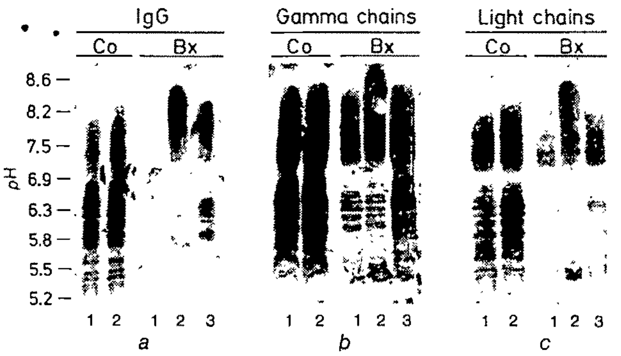

Fig. 3 *a*, Diversity of IgG; *b*, γ-chains; *c*, light chains of the control (Co) and bursectomized (Bx) chickens. Only bursectomized birds with serum IgG > 10% of the control value were selected for diversity analysis. Serum samples (2 μl) were electrofocused in 1% agarose gel in the absence (*a*) or presence (*b*, *c*) of 0.1 M mercaptoethanol[11]. After electrofocusing, proteins were transferred to a nitrocellulose sheet[11] and then the sheet was stained with the following antibodies. *a*, *b* Stained with the same procedure as in Figs 1 and 2 using rabbit antiserum against chicken γ-chain[8] at the first step. *c*, First incubated with monoclonal mouse anti-chicken light chain[13], then with rabbit anti-mouse IgG (Dako-immunoglobulins) and finally with alkaline phosphatase-conjugated pig anti-rabbit IgG (Orion Diagnostica). The *p*H gradient of the gel as measured with a surface electrode is indicated on the left. Light chains of both normal chickens reveal 26 separate bands at *p*H values 5.2–6.9 (concentration of total serum immunoglobulins 20.4 and 12.3 mg ml^{-1}) whereas two of the bursectomized chickens show 11 bands (concentration of total serum immunoglobulins 6.8 and 2.3 mg ml^{-1}) and the third showed 20 bands (concentration of total serum immunoglobulins 14.3 mg ml^{-1}) in this same area, indicating limited diversity of bursectomized birds show the same or even greater light-chain diversity than the controls. The mean isoelectric points of the light chains of bursectomized chickens are more basic than normal. In contrast, γ-chains of the bursectomized chickens have normal diversity.

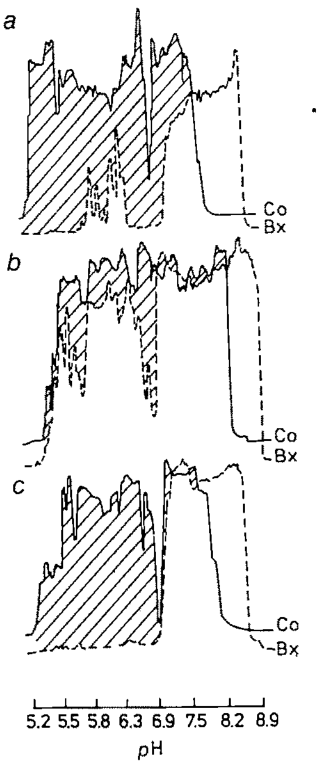

Fig. 4 Densitograms of the isoelectric focusing patterns of: *a*, whole IgG; *b*, gamma chains; *c*, light chains of one control (Co) and one bursectomized (Bx) chicken. These densitograms are made from isoelectric focusing patterns of the chickens Co 1 and Bx 2 in Fig. 3.

transferred to nitrocellulose sheets[11,12]. Immunoglobulins on the sheets were identified by an indirect immunoenzymatic staining[11] using polyclonal rabbit antibodies to γ-chain[8] and monoclonal mouse antibodies to light chain[13] (gift from Dr Max Cooper).

Bursectomized chickens had entire IgG molecules containing both heavy and light chains of apparently normal molecular weight (for γ-chain ~70,000 and for whole molecule ~190,000; Fig. 1). γ-chains of the bursectomized and control chickens showed identical cleavage patterns with three different proteases (Fig. 2), which suggests that their major structural fragments are similar and that they are expressed after similar gene rearrangement. Thus, IgG from bursectomized chickens exhibited no detectable structural abnormalities. However, whole IgG molecules of the bursectomized chickens had more basic isoelectric points than those of the controls (Fig. 3*a*). This was not due to a change in γ-chains, because they showed a normal diversity in isoelectric points (Fig. 3*b*). Instead, bursectomy decreased the amount of acidic light chains to an almost undetectable level without having any corresponding effect on the amount of basic light chains (Fig. 3*c*). Thus, alterations in the isoelectric spectra of the whole bursectomized IgG result from alterations in the light chains. This finding is clarified further in Fig. 4. The results clearly suggest abnormally limited diversity in these light chains.

Normal concentration of serum immunoglobulins does not necessarily imply normal immunoglobulin diversity and antigen binding capacity[14]. In this respect, the bursectomized chickens closely resemble human patients suffering from antibody deficiency with normal serum immunoglobulins[15,16]. Our finding of limited diversity of light chains in the bursectomized chickens is supported by the previous findings of Huang and Dreyer[17], who used testosterone bursectomy *in ovo* at day 11 of incubation. They concluded that bursectomy at day 11 of incubation blocks the generation of new clones of B cells. However, when bursectomy is performed 4 days after hatching a normal diversity of antibodies to human serum albumin develops[18].

Both somatic recombination and somatic mutation diversify the genetic information coded by the germ line genome. Somatic mutation, which alters bases throughout the sequences coding for the variable region, amplifies the diversity arising through recombination[19]. The isoelectric spectra of light chains of bursectomized chickens indicate that they consist of more basic amino acids than normal and may represent germ-line specificities. The antigen specificities of these antibodies have not yet been determined. The number of genes coding light-chain variable regions is not known in the chicken, but it is very probable that the number is small as in the human, and the diversity is generated mostly by somatic mutations[20]. Abnormality only in the light chains of the bursectomized chickens, on the other hand, indicates either that the specific influence of the bursa of Fabricius on B-cell development occurs late in the history of the B-cell clones, or that the normal diversity of the γ-chains observed in isoelectric focusing is generated with high numbers of variable-region genes.

Thus, our findings in bursectomized chickens of immunoglobulins without detectable antigen specificities and of abnormal diversity of light chains suggests that the bursa of Fabricius creates and expands the antibody repertoire by regulating somatic diversification, especially somatic mutations.

We thank Dr Max Cooper for monoclonal mouse anti-chicken light chain antiserum and him and Drs Irving Weissman, Matthias Wabl and Eugene Butcher for critical reading of this manuscript, Soile Niittoaho for technical assistance and Dr Timo Hyypiä for advice. This work was supported by grants from the Sigrid Jusélius Foundation and the Finnish Cancer Union.

Direct evidence for an integrated function of J chain and secretory component in epithelial transport of immunoglobulins

P. Brandtzaeg* & H. Prydz†

* Laboratory for Immunohistochemistry and Immunopathology, Institute of Pathology, and † Research Institute for Internal Medicine, University of Oslo; The National Hospital, Rikshospitalet, Oslo 1, Norway

J chain is a polypeptide of molecular weight (M_r) ~ 15,000 common to human dimeric IgA and pentameric IgM[1,2]. These immunoglobulin polymers show a high affinity for secretory component (SC) *in vitro*[3,4], a feature that, in some studies, has been claimed to be a function of the J chain[5,6]. SC is a glycoprotein of M_r ~80,000 which is expressed on the basolateral surfaces of secretory epithelial cells[7,8] where, according to a current hypothesis, it may act as a receptor for dimeric IgA and pentameric IgM[9] which are selectively transported through secretory epithelial cells into exocrine fluids[10,11]. Previous studies, however, have not excluded the possibility that secretory cells express isotype-specific Fc receptors for IgA and IgM which may be involved in epithelial transport. We now report that the adsorption of immunoglobulin polymers to SC-expressing epithelial cells depends solely on a J chain-determined binding site. This finding lends biological significance to the striking J-chain expression shown by immunoglobulin-producing immunocytes in secretory tissues[12–14].

Almost 20 years ago Tomasi *et al.*[15] showed that the major immunoglobulin class present in human secretions is dimeric IgA covalently bound to an epithelial component now called SC. Pentameric IgM is similarly enriched in most exocrine fluids in contrast to IgG[10]; and secretory IgM is also associated with SC, although not in a covalently stabilized complex[11].

At least seven models have been proposed for the epithelial transport of IgA (reviewed in ref. 9). The common transport model for dimeric IgA and pentameric IgM proposed by one of us in the early 1970s[16,17] has subsequently gained considerable support from observations of both normal[8] and neoplastic[18,19] living epithelial cells. This model postulates that the J chain and SC represent the 'lock and key' in the selective external transport. It has recently been shown that SC is synthesized as a transmembrane protein of M_r ~95,000 (ref. 20). This larger SC precursor may alone, or in combination with other binding factors, constitute the actual receptor.

As it is known that human hepatocytes contain an IgA-binding site unrelated to SC[9] and that subsets of T and B lymphocytes[21,22], monocytes[23], alveolar macrophages[24] and granulocytes[23] express Fcα receptors, we believed it important to examine whether this is the case also for human secretory epithelial cells. In addition, we wanted to test directly the role of J chain in immunoglobulin binding to cell membrane-associated SC.

Experiments were performed with cells from the colonic carcinoma line designated H29 (ref. 25). The subclone HT29.E10 (used with the permission of Dr K. E. Mostov; ref. 20) was maintained as monolayers in 75 cm^2 Costar flasks at 37 °C with an atmosphere of 5% CO_2 in McCoy's Modified 5A medium supplemented with 15% fetal bovine serum, 2 mM glutamine, 50 units ml^{-1} penicillin and 50 µg ml^{-1} streptomycin. The cultures were split by 7-min treatment with 0.05% (w/v) trypsin and 0.02% (w/v) EDTA (Trypsin–EDTA; Flow), washed and seeded into Leighton tubes. Coverslips from 2–6-day-old cultures were divided into small areas that were subjected to tests with various human protein preparations (Table 1).

Direct immunofluorescence showed that only 20–40% of the living cells expressed substantial amounts of SC. After preincubation with polymeric IgA containing appropriate amounts of J chain (>4 mg per 100 mg), paired staining showed strict correspondence between SC expression and IgA binding (Fig. 1*a*); a positive result was obtained with staining end points of $<0.02\ \mathrm{g\,l^{-1}}$ for unlabelled and $<0.01\ \mathrm{g\,l^{-1}}$ for fluorescein-labelled preparations (Fig. 2). The only exception was colostral IgA which did not produce binding below 1 g l^{-1} (Fig. 1*c*). Monomers of IgA having no J chain showed no adsorption to the cells (Fig. 2*b*), even when tested at $\geqslant 3.5\ \mathrm{g\,l^{-1}}$ (Fig. 2). Conversely, three monomer preparations with small amounts of J chain showed binding between 0.3 and 1.8 g l^{-1} (Fig. 2), probably reflecting the presence of contaminating polymers. Four IgA polymers deficient in J chain produced staining end points comparable to the latter three monomer preparations when J-chain content and percentage SC-binding capacity were taken into account (Figs 1*d*, 2). The same was true for a J chain-deficient polymeric IgM in contrast to the three pentamers with normal J-chain content (Figs 1*e*, *f*, 2). On the whole, there was good agreement between the SC-binding capacity of the various preparations and their staining end points when tested on living cells (Fig. 2).

No binding of IgA or IgM was observed with epithelial cells lacking SC (Fig. 1*a*, *e*). Conversely, IgG at 4 g l^{-1} was largely adsorbed to such cells (Fig. 1*g*), probably reflecting the presence of Fcγ receptors, which may be expressed by carcinoma cells[26]. This finding indicated that the amount of these receptors might be related to cellular de-differentiation resulting from clonal diversification as preservation of SC expression is found mainly in well-differentiated colonic carcinomas[27].

In previous binding studies with the HT29 cell line, no dose–response analyses were performed. One study included dimeric IgA, monomeric IgA and IgG only at 0.2 g l^{-1} (ref. 19) and another used a much higher (4 g l^{-1}) concentration[18]. Although no binding was reported for monomeric IgA, the possibility could not be excluded that the positive results obtained with polymers were due to isotype receptors because paired staining for ligand and SC was not performed. Indeed, it has been shown that the Fcα receptors present on granulocytes show much higher (~10 times) binding activity for dimeric than for monomeric IgA[23]. We do not believe that tests with colostral IgA are an appropriate control; its incorporated SC could, by steric hindrance, have interfered with binding to putative Fcα receptors. Blocking by preincubation with antibodies to SC[5,6] is, using a similar reasoning, an unsatisfactory control.

Thus, for the first time we have excluded the possibility that 'conventional' Fcα and Fcμ receptors are significantly involved in the adsorption of immunoglobulin polymers to human secretory epithelial cells; a J chain-determined binding site specific for SC seems to be the decisive structure. Although much work has been done to elucidate a role for the J chain in B-cell differentiation, there is as yet no clue to this end[28]. Immunoglobulin-producing cells may express cytoplasmic J chain regardless of concurrent isotype[12]; but the combination

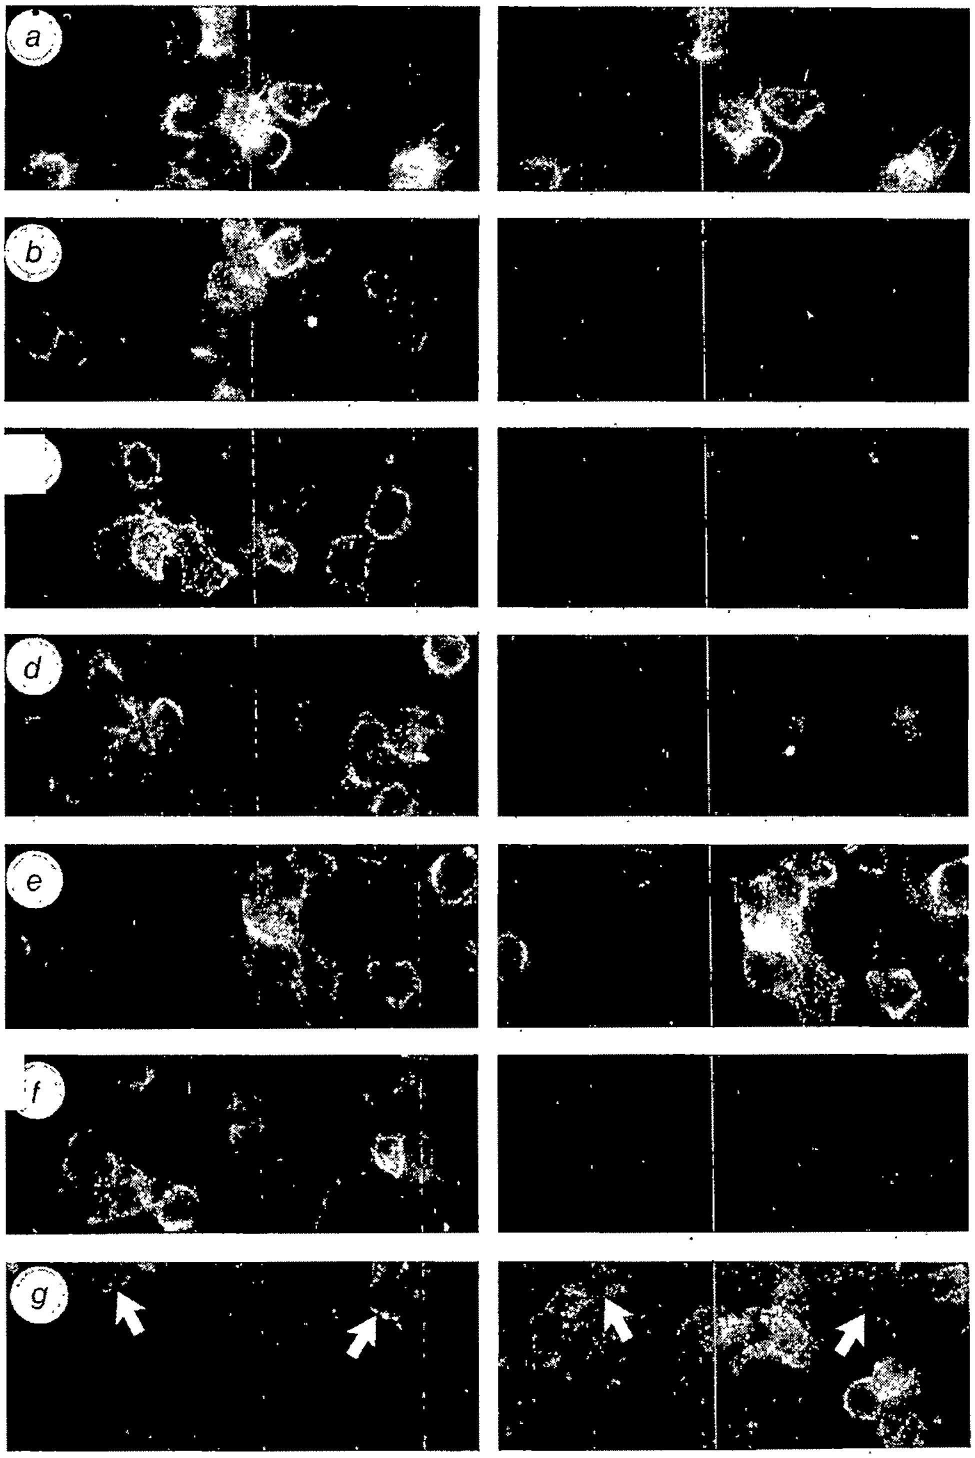

Fig. 1 Paired immunofluorescence staining of vital HT29.E10 monolayer preparations to demonstrate concurrent surface expression of SC (left panel, 10-s exposure of rhodamine emission) and binding of IgA, IgM or IgG (right panel, 20-s exposure of fluorescein emission). *a*, Binding of fluorescein-labelled polymeric IgA at 0.15 g l^{-1}. *b*, Lack of binding of fluorescein-labelled monomeric IgA at 1.2 g l^{-1}. *c*, Absence of binding of fluorescein-labelled colostral IgA at 1.0 g l^{-1}. *d*, Lack of binding of J chain-deficient polymeric IgA at 2.9 g l^{-1}. *e*, Binding of polymeric IgM at 0.25 g l^{-1}. *f*, Absence of binding of J chain-deficient polymeric IgM at 0.25 g l^{-1}. *g*, Binding of IgG at 4.0 g l^{-1} obtained mainly with SC-negative cells; the locations of two SC-positive cells are indicated by arrows. ×390.

Methods: Protein binding to living cells was tested by incubating unfixed monolayers at room temperature for 45 min with various concentrations of human immunoglobulin preparations which were applied either unlabelled or conjugated with fluorescein isothiocyanate as indicated. Dilutions (4.0–0.005 g l^{-1}) were done in phosphate-buffered isotonic saline (PBS), *p*H 7.5, containing bovine serum albumin (120 g l^{-1}). After washing in PBS (10 min), the monolayers were incubated (30 min) with a combination of rhodamine conjugate specific for SC and fluorescein conjugate specific for the appropriate immunoglobulin isotype. The characteristics of these fluorochrome conjugates have been reported previously[39]. After a final wash in PBS, all preparations were fixed in 96% ethanol (15 min), rinsed in PBS, and mounted in a polyvinyl alcohol medium for fluorescence microscopy[8].

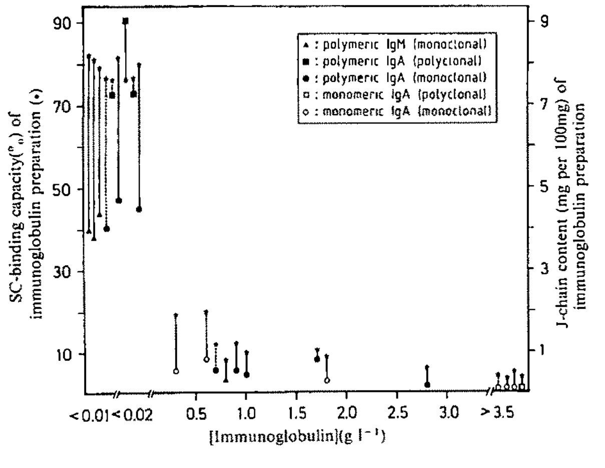

Fig. 2 Staining end points for binding of various human immunoglobulin preparations to the surface of HT29.E10 cells as determined by indirect immunofluorescence (see Fig. 1). The results were based on microscopic evaluation of 175 monolayer preparations incubated with IgA and 45 incubated with IgM. The abscissa gives the concentration of immunoglobulin needed for binding to SC-expressing epithelial cells. The plots of SC-binding capacity (*) and J-chain content (different symbols as indicated) are connected by vertical lines (broken for fluorescein-labelled IgA preparations); these data were obtained as described in Table 1.

Table 1 Characteristics of human immunoglobulin preparations used in binding studies with HT29.E10 cells

No. and type of preparation		Approximate composition	Molar *F*/*P* ratio	J-chain content (mg per 100 mg)	SC-binding capacity (%)*
1	Pc Pm IgA	78% Dimers 15% Larger polymers 7% Monomers	4.0	7.3	76
1	Pc Pm IgA	78% Dimers 15% Larger polymers 7% Monomers	None	7.3	76
2	Pc Pm IgA	70% Dimers 25% Larger polymers 5% Monomers	None	9.3	76
3	Mc Pm IgA	70% Dimers 20% Larger polymers 10% Monomers	0.9	4.0	77
4, 5	Mc Pm IgA	Mainly trimers 5–10% Monomers	None	4.5–4.7	80
6	Mc Pm IgA	20% Dimers 40% Trimers 40% Larger polymers	3.0	0.6	12
6	Mc Pm IgA	20% Dimers 40% Trimers 40% Larger polymers	None	0.6	12
7–9	Mc Pm IgA	40–60% Dimers 25–50% Larger polymers 10–20% Monomers	None	0.2–0.8	7–10
10	Colostral IgA	75% Dimers 25% Larger polymers	3.2	ND	19
11	Mc Mm IgA	Mainly monomers	3.6	0	4
12	Pc Mm IgA	Mainly monomers	None	0	4
13,14	Mc Mm IgA	Mainly monomers	None	0	4–5
15–17	Mc Mm IgA	Mainly monomers	None	0.3–0.8	9–20
18–20	Mc Pm IgM	Mainly pentamers	None	3.9–4.4	80–82
21	Mc Pm IgM	Mainly hexamers	None	0.5	8

Pc, polyclonal; Pm, polymeric; Mc, monoclonal; Mm, monomeric. Purification was achieved by anion-exchange chromatography and gel filtration[6]. It is unknown whether the J chain-deficient polymers had been produced as such or whether the J chain had been removed by selective proteolysis *in vivo* or *in vitro*[36]. The fact that preparation 21 consisted mainly of hexamers[33] suggests the former possibility. The approximate composition of each preparation was determined by density gradient centrifugation[6]. The *F*/*P* (fluorochrome/protein) ratio was determined as described previously for preparations labelled with fluorescein isothiocyanate[37]. The conjugation method and purification of the conjugates by anion-exchange chromatography followed standardized procedures[37]. J-chain content was measured for reduced preparations by an immunochemical method described previously[38]. ND, not determined.

* Percentage of 2.5 μg iodinated SC spontaneously associated with 100 μg protein as determined by density gradient centrifugation[3].

of J chain and immunoglobulin occurs only in IgA and IgM cells, thereby generating functional SC-binding sites already at the intracellular level[14]. Several studies have shown that the cytoplasmic appearance of J chain depends on B-cell stimulation[28,29]; clonal maturity may, on the other hand, result in repression of J chain synthesis[30]. The immunocytes populating secretory tissues apparently belong to relatively immature memory clones[31]; this feature probably explains the fact that not only do more than 90% of their IgA- and IgM-producing cells express J chain but so do most of the IgD-producing cells and 50–70% of the IgG-producing cells at these sites[14].

The obvious functional goal of J-chain expression at a certain stage of clonal B-cell differentiation is generation of SC-binding IgA and IgM locally where external transport through SC-positive epithelium can occur readily. However, it is not clear how the J chain is involved in the binding site; it may act solely by causing structural modification of the α and μ chains present in the immunoglobulin polymers. Studies both *in vitro* and *in vivo* have suggested that the J chain is not required absolutely for polymerization[32–34], but it clearly facilitates intracellular formation of selected polymer species that can combine with SC[14]. Despite the fact that purified dimeric J chain affords only marginal blocking of SC binding to dimeric IgA and pentameric IgM[35], the possibility of direct non-covalent interactions between polymer-associated J chain and SC cannot be excluded.

This study was supported by the Norwegian Cancer Society, the Norwegian Research Council for Science and the Humanities, the Norwegian Council for Cardiovascular Diseases, and Anders Jahre's Foundation. We thank Drs Sylvia Crago and Jiri Mestecky for providing the HT29.E10 cells.

Antibody diversity is generated by the combinatorial association of multiple distinct genetic segments (variable (V), joining (J) and diversity (D) light (L) and heavy (H) chains—V_L, J_L and V_H, D, J_H) and amplified somatically by three or four different mechanisms[1–6]. The κ system in mouse and human consists of 50–100 V_κ segments associated with a cluster of four or five functional J_κ segments, located 2.5 kilobases (kb) 5′ to a single C_κ gene[7–10]. The third hypervariable region (CDR3), which is part of the antibody combining site, is usually nine amino acids long in human and mouse κ chains. It is encoded by the last seven codons of the V_κ segment and the first two of the J_κ segment, one codon sometimes being added or deleted between V and J by junctional variation[2]. In the rabbit, the $C_\kappa1$ gene which encodes the major isotype[11–14], is associated with a cluster of five J_κ segments, only one of which seems to be functional[11], thus significantly decreasing the combinatorial potential. However, amino acid sequence comparison has revealed extensive heterogeneity in the length of rabbit CDR3 (ref. 15), suggesting the existence of a D segment analogous to that in the heavy-chain system. We show here that rabbit V_κ genes have several additional nucleotides at their 3′ ends. Thus, even with a single functional J_κ segment, high CDR3 diversity can be generated based on the length heterogeneity of V_κ germ-line segments and their greater length, which might leave scope for an increased junctional deletion.

We have isolated many recombinant cosmids from a rabbit liver genomic library[13] and find that each DNA insert of ~35 kb contains four to six *Eco*RI fragments that hybridize to a V_κ probe; this suggests that rabbit V_κ genes are clustered and spaced 6–8 kb apart. Human and mouse V_κ genes, with few exceptions[16], seem to be separated by 15 or 20 kb[17,18]. By Southern genomic blot experiments (Fig. 1), a single V_κ probe can detect as many as 25–30 restriction fragments displaying different intensities, and reveals little restriction site polymorphism between four independent individuals. Compared with mouse and human, where a single V_κ probe detects, respectively, 1–15 and 15–20 restriction fragments[19,20], in the rabbit at least one group of cross-hybridizing V_κ genes is greatly amplified. However, V_κ subgroups are not clearly defined[21,22]. It remains to be determined whether the probe can detect a large proportion of the V_κ gene repertoire, as in human, or only a small subset of this repertoire, as in mouse.

Figure 2 shows the nucleotide sequences of four unrearranged V_κ segments, isolated by pairs on two independent recombinant cosmids. They contain two exons, as in human and mouse[23,24], a small exon encoding most of the peptide leader sequence, separated by a 123-base pair (bp) intron from a large exon encoding the end of the signal peptide and the V_κ region. Whereas many human and mouse V_κ and V_H pseudogenes have been reported[23–25], these four rabbit V_κ genes show apparently normal signal peptide and V_κ coding sequences. The deduced amino acid sequences are 85% homologous (apart from CDR3, see also Fig. 3), the most common amino acid sequence being that defined by Kabat *et al.*[15]. As in mouse and human where signal peptides are usually 20 or 22 amino acids long[23,24], the ATG codon (position 143 in Fig. 2) gives a 22 amino acid signal peptide. We also note, 30 bp upstream, another in-phase ATG codon giving rise to a 32 amino acid signal peptide[26]. The promoter sequences (CAAT-like and TATA-like boxes) are located at the same distance from the ATG codon-22 as in the human HK102 V_κ gene (Fig. 2). Percentages of similarity given in Table 1 show that signal peptides are highly conserved and that rabbit flanking sequences and introns are more conserved than the V_κ coding regions. Furthermore, as shown in Fig. 2, base pair substitutions are preferentially clustered in the first third and in the CDR3 regions of the V_κ genes. Such patterns of segmental homology are highly characteristic of gene conversion events[17,27–31].

As in human and mouse, the recombination signal at the end of the V_κ coding sequence consists of the heptamer CACAGTG separated from the nonamer ACAAAAACC by a 12-bp nonconserved spacer[1]. The signal sequences of V18a and V19a are perfectly conserved. V18b and V19b have, respectively, one base pair deletion and three base pair substitutions in the nonamer.

Table 1 Percentages of similarity between V_κ genes

	5′	P_L	Int	V_κ	3′
V18a/V18b		95.4 (90.9)	95.9	88.4 (79.2)	95.0
V19a/V19b	89.0	93.9 (90.9)	92.7	86.4 (80.6)	92.0
V18/V19	90–95	95–97 (91–100)	94–97	81–88 (71–81)	91–96
V18a/HK102	72.9	92.4 (81.8)	62.1	74.0 (61.0)	72.4

Nucleotide sequences of the 5′ flanking (5′), leader peptide (P_L), intron (Int), V_κ coding (V_κ) and 3′ flanking (3′) regions were compared and percentages were calculated as: number of substitutions to number of nucleotides compared. Each deletion or insertion of nucleotide (whatever the number) was scored as a single mutation. Numbers in parentheses correspond to percentages of similarity at the amino acid level. Numbers given for 18/19 (lane 3) correspond to the minimum and maximum values obtained when a V18 gene (a or b) was compared with a V19 gene (a or b). Human V_κ HK102 is from ref. 23.

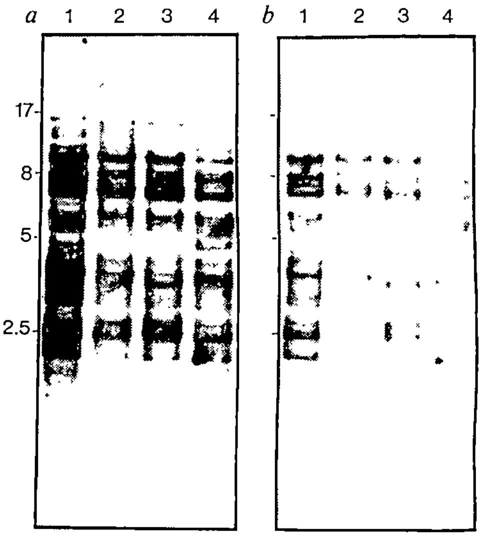

Fig. 1 Southern blot analysis of four individual rabbit DNAs using the V19a gene as a probe. Liver DNAs of homozygous *b9/b9* (lane 1), *b4/b4* (lane 2), *b5/b5* (lane 3) and *b6/b6* (lane 4) rabbits were digested with *Eco*RI, electrophoresed on a 0.7% agarose gel and transferred to nitrocellulose[34]. Hybridization was according to ref. 35. The probe was the 1.5 kb V19a *Eco*RI insert (see Fig. 2 legend); this was purified, ligated to itself and nick-translated, as already described[35]. *a*, The blot was washed in low-stringency conditions, at 65 °C in 2×SSC, 0.1% SDS for 90 min with three changes, and autoradiographed for 2 days. *b*, The same blot was then washed in high-stringency conditions, at 65 °C in 0.1×SSC, 0.1% SDS for 30 min, and autoradiographed for 15 days.

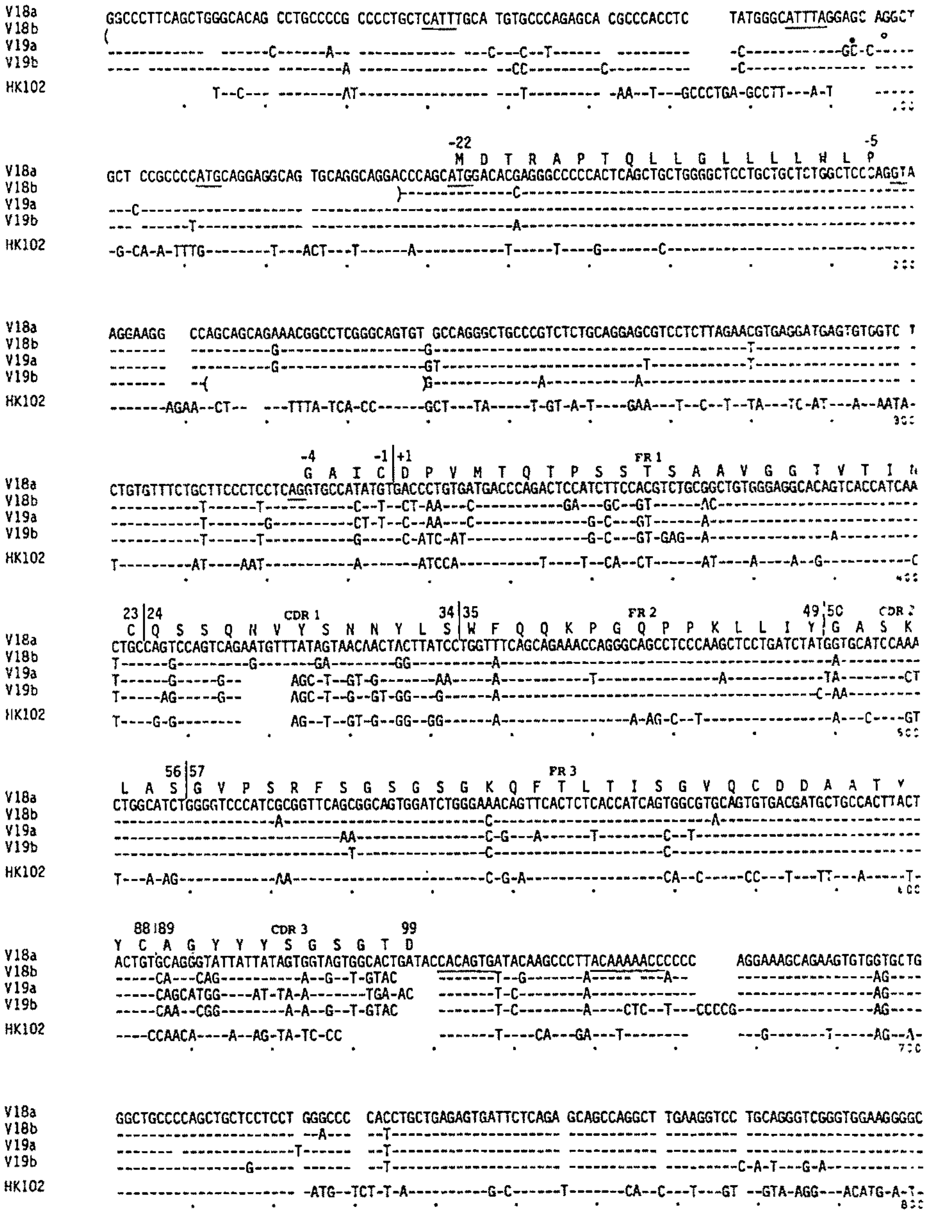

Fig. 2 DNA sequence comparison of four germ-line rabbit V_κ genes and the human HK102 V_κ gene[23]. A rabbit $V_\kappa + C_\kappa$ cDNA probe was constructed from *b5/b5* rabbit spleen mRNA, as previously described[36]. A cosmid library of adult *b4/b4/* rabbit liver DNA fragments[13] was screened by *in situ* hybridization with the nick-translated $V_\kappa + C_\kappa$ cDNA insert, as already reported[13]. Two recombinant cosmids, V4R-18 and V4R-19, were digested with *Eco*RI and analysed by Southern blot hybridization[34] with the cDNA probe. Two positive *Eco*RI restriction fragments were chosen from each cosmid (2.1 kb (V18a) and 2.9 kb (V18b) from V4R-18; 1.3 kb (V19a) and 2.2 kb (V19b) from V4R-19). *Sau*3A, *Hae*III or *Ava*II restriction digests of the four *Eco*RI fragments were subcloned into M13mp701 vector and sequenced on both strands by the chain-termination method[37–39]. The amino acid translation of the V18a gene is given in the one-letter code[40] and the numbering is according to ref. 15. The frameworks (FR) and complementarity-determining regions (CDR) are indicated. Dashes indicate nucleotide identities with the V18a nucleotide sequence. Blank spaces have been introduced to maximize homology. Parentheses in V18b and V19b genes correspond to unidentified residues, and alignments have been made in accordance with V18a gene and restriction mapping analysis. Promoter signal sequences, translational initiation codons, splicing signal and recombination recognition signal sequences are underlined.

Because the rabbit κ genes conform to the 12/23-bp rule, we can exclude the possibility that an intermediate *D* segment accounts for the high heterogeneity in CDR3 length. As shown in Fig. 2, the rabbit V_κ genes are very heterogeneous in length and sequence in their CDR3 regions, and are longer than in human and mouse. They vary from 30 to 35 bp and can code for 10 or 11 amino acids, whereas in human and mouse, CDR3 regions are usually 22–23 bp encoding 7 amino acids, with two exceptions being 25 bp long[32,33].

In fact, the rabbit CDR3 region has been shown to contain up to six more amino acids than human and mouse[11]. However, in the two cases where there are six extra amino acids, the sixth (Thr or Gly) could be derived from the J_κ codon (Ala) by a single (somatic?) point mutation. The four rabbit V_κ germ-line genes in the present study can code for three or four extra amino acids, or four or five, depending on junctional variation[2]. It is thus very likely from our data, that the extra amino acids found in the rabbit κ-chains are entirely encoded by the V_κ genes, without the need for an N region as in the heavy-chain system[3].

Recombination between V_κ and J_κ segments may delete nucleotides in the V_κ genes, as in the J_κ segment. Junctional deletions have been observed mainly at the V_H–*D* and *D*–J_H junctions, with only rare exceptions in the light-chain system[32]. As the signal sequences involved in the V_κ–J_κ junction are identical in rabbit and mouse or human, the junctional deletion or variation must follow the strand cut during recombination. This deletion mechanism is probably of the same kind as in the heavy-chain system. It might have been selected in the rabbit because of structural constraints linked to the length of J_κ and V_κ segments. Thus, the additional nucleotides at the 3′ end of rabbit V_κ genes are somewhat analogous to the *D* segment of the heavy-chain system. They leave scope for an increased junctional deletion mechanism during rearrangement, which in turn generates high CDR3 diversity.

Junctional deletion of the rabbit J_κ codons means that they are no longer involved in the formation of CDR3 (ref. 11) and thus J_κ segments can be inactivated during evolution, without serious consequences, provided, of course, that one J_κ segment remains functional. The rabbit V_κ genes may correspond to an ancestral system from which the human and mouse V_κ genes have been derived by nucleotide deletions during evolution of these species. In this respect, it is interesting that human λ light chains also show CDR3 length heterogeneity[15], suggesting a possible common origin for the human V_λ and rabbit V_κ genes.

In conclusion, immunoglobulin genetic segments can to variable extents use the mechanisms available for the generation of antibody diversity. κ Light-chain CDR3 diversity in human and mouse is based on combinatorial potential and is amplified by a limited junctional variation mechanism. Our data show that in the rabbit only a single functional J_κ segment is required.

Fig. 3 Deduced amino acid sequences of the four rabbit germline V_κ genes. The one-letter code is used[40] and numbering is according to ref. 15. Dashes indicated identities with the amino acid sequence of the V18a gene. Gaps have been introduced to maximize homology. Also given is the deduced amino acid sequence of the human HK102 V_κ gene[23]. Kabat's sequence is a compilation of rabbit κ light-chain amino acid sequences and represents for each residue the most common amino acid observed at that position[15].

The diversity is based on the greater length and length heterogeneity of germ-line V_κ-CDR3 regions, and is highly amplified by nucleotide deletions in the J_κ and perhaps V_κ segments, during *V–J* recombination. Diversity in rabbit κ light chains mimics the mechanisms of CDR3 diversity in human and mouse heavy-chain systems, where V_H segments are highly conserved at their 3′ ends, and heterogeneity in length and sequence is provided by the *D* segments, the N region and the junctional deletion.

We thank Dr J. J. Panthier for helpful discussions and Drs C. Henderson and G. Langsley for critical reading of this manuscript. Transcription of plant defence genes in response to UV light or fungal elicitor

Joseph Chappell* & Klaus Hahlbrock

Biologisches Institut II der Universität, D-7800 Freiburg, and
Max-Planck-Institut für Züchtungsforschung, D-5000 Köln 30, FRG

The synthesis of secondary metabolites in response to stress conditions has been implicated as a major defence response of higher plants[1]. Cell suspension cultures of parsley (*Petroselinum hortense*) have been studied extensively as a model system and shown to respond to UV irradiation and treatment with fungal elicitor by the synthesis of flavonoids and furanocoumarins, respectively[2,3]. The induced synthesis of these compounds might afford the plant protection against the respective environmental hazards, because flavonoids strongly absorb UV light and furanocoumarins possess fungitoxic properties[4]. The production of each class of compound is preceded by the induction of groups of coordinately regulated enzymes[2,5–8], based on rapid changes in amounts and activities of the corresponding messenger RNAs[9,10]. We now report that these changes are due to transient increases in the transcription rates of the respective genes, which indicates that gene activation has an important role in UV and disease resistance in higher plants.

The three enzymes of general phenylpropanoid metabolism (group I) are co-induced in cultured parsley cells with either the flavonoid glycoside pathway, comprising some 16 enzymes, (group II) or the less clearly defined furanocoumarin pathway (group III), depending on whether UV light or a pathogen-derived elicitor[11] is used as inducing agent[2,4,6,8]. The effect of UV light is highly selective for the synthesis of flavonoids, whereas various metabolic changes are induced by the elicitor[4,10]. Cloned complementary DNA copies of mRNAs coding for two enzymes of group I, phenylalanine ammonia-lyase (PAL; EC 4.3.1.5) and 4-coumarate: CoA ligase (4CL; EC 6.2.1.1.2), and for chalcone synthase (CHS), a member of group II, have recently been used to show that the accumulation of flavonoids or furanocoumarins is associated with rapid increases in the respective mRNAs[9,10]. The same cDNAs were used in the present study, where nuclei were isolated from UV-irradiated and elicitor-treated cells, and RNA synthesis was continued *in vitro* in the presence of ^{32}P-UTP. The radioactive RNA was then hybridized to the cDNA inserts bound to diazobenzyloxymethyl (DBM) filters or to DNA–nitrocellulose blots. The amount of ^{32}P-UTP incorporated into a specific mRNA is taken as a measure of the polymerase activity associated with the respective gene at the specific time of nuclei isolation. Because it is unlikely that initiation of transcription takes place in these conditions[12], we are measuring only the completion of transcripts initiated *in vivo* before the nuclei were isolated.

Irradiation of the cell cultures with UV light for a standard 2.5-h period[5,7] induced transient increases in the transcription rates of the genes coding for PAL, 4CL and CHS mRNAs. Figure 1 shows the results for PAL and CHS, confirming the previously observed small, but distinct, difference in the timing of induction of groups I and II[4,5,10]. Changes in the rates of 4CL mRNA synthesis were similar to those obtained for PAL, but as expected[7], the amounts of hybridizable material were much smaller and more difficult to determine accurately (~2 parts per million (p.p.m.) at the peak around 4 h after the onset of induction).

Similar results were obtained in both types of determination, DNA blot (Fig. 1*a*) and DBM filter (Fig. 1*b*) hybridizations. The CHS cDNA used here encompasses the entire coding sequence of the mRNA[13] and contains an internal *Pst*I site. On isolation of the cDNA insert from the *Pst*I site of the cloning vector, plasmid pBR322, two fragments of 720 and 780 base pairs were obtained (Fig. 1*a*).

---

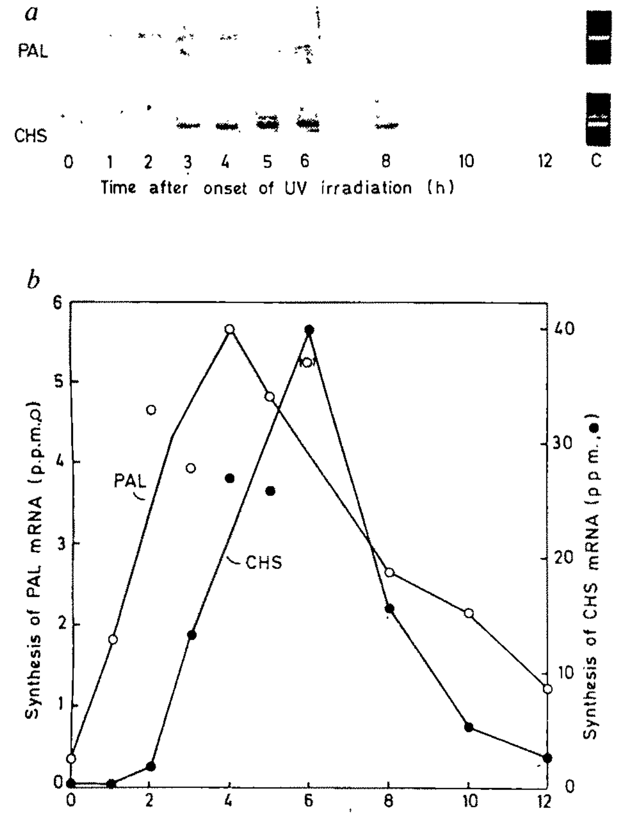

Fig. 1 Changes in the transcription rates of PAL and CHS genes in nuclei isolated from parsely cell cultures at various times after the onset of UV irradiation for 2.5 h. The ^{32}P-RNA synthesized by isolated nuclei was hybridized either to DNA blots (*a*) or to DBM filters (*b*) containing cDNA inserts complementary to PAL and CHS mRNAs. The amount of RNA hybridizing to a specific cDNA was determined by autoradiography (*a*) or by scintillation spectrometry (*b*). A control (C) shows the cDNA inserts stained with ethidium bromide.

Methods: A cell suspension culture of parsley (*Petroselinum hortense*) was grown in continuous darkness for 7 days after subculturing in a simple, synthetic medium[7] and then irradiated with UV light[5,7] for 2.5 h. Cells were collected at the indicated times after the onset of irradiation. Nuclei were isolated from the cells according to Willmitzer and Wagner[14] with the following modifications. Cells (25–40 g) were gently stirred in 100 ml of 0.7 M mannitol, 10 mM methane ethane sulphonate (MES) *p*H 5.8, 5 mM EDTA, 0.1% bovine serum albumin (BSA) (w/v), 0.2 mM phenyl methylsulphonyl fluoride (PMSF) containing 50 mg cellulase (Onozuka) and 10 mg Macarzyme (Onozuka) for 15 min at 25 °C, and the partial protoplastic cells were homogenized three times with an Ultra-turrax for 15 s in 0.25 M sucrose, 10 mM NaCl, 10 mM MES *p*H 6.0, 5 mM EDTA, 0.25 mM spermine-HCl, 0.5 mM spermidine-phosphate, 20 mM mercaptoethanol, 0.2 mM PMSF, 0.6% Triton X-100 (w/v) and 2% dextran (40,000) (w/v). In 100-μl reaction volumes, 10^7 isolated nuclei completed transcripts initiated *in vivo* in 75 mM $(NH_4)_2SO_4$, 8 mM $MgCl_2$, 0.5 mM each of GTP, ATP and CTP, 8% glycerol (v/v), 20 mM Tris-HCl *p*H 7.8 and 100 μCi ^{32}P-UTP (400 Ci $mmol^{-1}$) for 30 min at 30 °C. The reaction was linear in these conditions for about 60 min. The RNA synthesized *in vitro* was isolated[15] and dissolved in 50% formamide, 4×SSPE, 0.02% each of Ficoll, polyvinylpyrrolidone and BSA (w/v), 200 μg ml^{-1} each of transfer RNA and poly(A)$^+$ RNA, and 0.2% SDS (w/v). The radiolabelled RNA (2×10^7 c.p.m. per sample) was then hybridized to 200 ng insert DNA transferred to GeneScreen (NEN) filters (*a*) or to DBM filters[16] containing 200 ng insert DNA (*b*). Hybridization was done in the same buffer containing 8% dextran sulphate (w/v) at 42 °C for 40–62 h. The filters were then washed three times with 2×SSC, 0.5% SDS at 60 °C for 30 min, once with 0.5×SSC, 0.5% SDS at 60 °C for 30 min, twice with 2×SSC and subsequently treated with 20 μg ml^{-1} RNAse A in the same buffer for 30 min at room temperature. The filters were finally washed twice in 2×SSC with 0.5% SDS and twice in the same buffer without SDS. Additional amounts of DNA did not increase the amount of RNA hybridization, and a linear relationship existed between the amount of RNA used and RNA hybridization. The ^{32}P-RNA hybridized was visualized by autoradiography of the DNA blots (*a*) or quantified by scintillation spectrometry of the radioactivity released by treating the DBM filter with 0.4 M NaOH (*b*). The lanes on the far right in *a* show the ethidium bromide-stained agarose gel before transfer of the cDNA insert to GeneScreen (NEN). Hybridization to DBM filters was corrected for background by subtracting the radioactivity released from a filter containing 200 ng λ dV DNA. Specific hybridization is presented as p.p.m. of input RNA. 3×10^7 c.p.m. of ^{32}P-RNA was used for each hybridization shown and the background hybridization was an average of 112 c.p.m. No corrections were made for the hybridization efficiency or size of the hybridization probe.

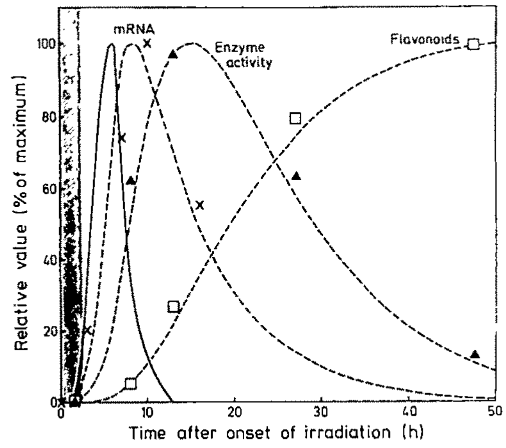

Fig. 2 Comparison of predicted and measured changes in CHS mRNA and enzyme activities and in flavonoid glycoside concentrations in UV-irradiated parsley cells. The shaded area indicates the length of the UV irradiation period. The solid curve represents the data shown in Fig. 1 for UV light-induced CHS gene transcription; this curve was used to calculate (broken curves) the expected changes in CHS mRNA and enzyme activity, and the accumulation of flavonoid glycosides, in the previously established conditions in which both the mRNA and the enzyme were rapidly degraded[5] but the flavonoids were not further metabolized[17]. In these conditions, the equation

$$dx(t)/dt = {}^0k_s(t) - {}^1k_d x(t) \qquad (1)$$

can be applied to calculate mRNA or enzyme activity changes (x) with time (t) from the respective zero-order rate constants of synthesis (${}^0k_s$) and the first-order rate constants of degradation (${}^1k_d$), and the equation

$$P(t) = \int_0^t E(\tau)\,d\tau \qquad (2)$$

describes the changes in the amount of products (P) accumulated with time(t; τ) as a result of changes in the rate-limiting enzyme activity (E)[4,5,18]. The symbols represent mean values of two measurements each of CHS mRNA (×), CHS activity (▲) and total flavonoids (□). Changes in levels of CHS mRNA and translational activity have previously been shown to follow the same kinetics[9,10].

Methods: Propagation and collection of cells at the indicated times, extraction procedures and measurements of hybridizable mRNA amounts[9,10], enzyme activity[19] and amounts of total flavone and flavonol glycosides[20] have been reported previously.

The apparent changes in the rates of transcription were not due to an attenuation of the transcription rates of particular genes in control cells, because the same results were obtained in conditions where the nuclei had been lysed and the DNA superstructure disrupted by high salt concentrations (data not shown). Furthermore, the transcription rate of a constitutively expressed mRNA, which is complementary to cloned cDNA from the plasmid pLF14 and codes for a protein of unknown function (J.C. and K.H., unpublished results), was constant throughout the experiment (Fig. 1) at ~20 p.p.m. Ribosomal RNA synthesis, measured using a cloned maize genomic fragment comprising a cluster of ribosomal genes (P. Schulze-Lefert and G. Feix, manuscript in preparation), showed an approximate doubling over controls with 4 h. The *in vitro* transcription of the PAL, 4CL and CHS genes was sensitive to 0.1–0.4 μg ml^{-1} α-amanitin, suggesting that these genes are transcribed by RNA polymerase II.

The UV light-induced changes in the rates of PAL and CHS mRNA synthesis have also been measured *in vivo* (Table 1). Both mRNAs were synthesized at much higher rates 3–4 h after the onset of UV irradiation than in control cells or at a later stage after induction. These changes were basically the same as those measured *in vitro* and further demonstrate that the PAL and CHS genes are under transcriptional control in UV-irradiated cells.

Figure 2 shows the causal relationship between the timing of changes in the rate of CHS mRNA synthesis and the kinetics of flavonoid accumulation. The timing of the entire sequence of events, as predicted from the induced changes in the rates of CHS gene transcription and the rates of mRNA and enzyme degradation (which are easily calculated from the respective half lives[4,5]), agrees with corresponding experimental results. Only a few time points are shown here for the changes in the

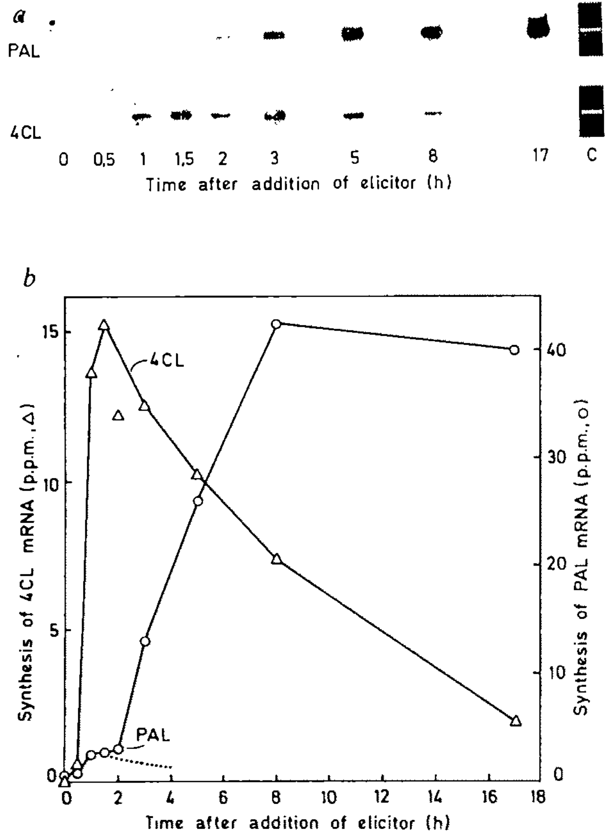

Fig. 3 Changes in the transcription rates of PAL and 4CL genes in nuclei isolated from cultured parsley cells at various times after the addition of elicitor. The ^{32}P-RNA synthesized by isolated nuclei was hybridized either to DNA blots (*a*) or to DBM filters (*b*) containing cDNA inserts complementary to the respective mRNA. The amount of RNA hybridizing to a specific cDNA was determined by autoradiography (*a*) or by scintillation spectrometry (*b*). A control (C) shows the cDNA inserts stained with ethidium bromide. The dotted line in *b* represents possible alternative changes in the rate of PAL mRNA synthesis (see text for discussion).

Methods: A cell suspension culture of parsley was treated at time 0 with $\sim 25\ \mu g\ ml^{-1}$ of a fungal elicitor prepared from the cell wall of *Phytophthora megasperma* f. sp. *glycinea*[11]. Culture conditions, nuclei isolation, RNA synthesis and hybridizations with PAL and 4CL cDNAs were as described for Fig. 1, except that 1.5×10^7 c.p.m. per hybridization were used. Specific hybridization, obtained by correction for an average background of 178 c.p.m., is expressed as p.p.m. of input RNA. No corrections for hybridization efficiency or the size of the hybridization probe were made.

amount of hybridizable mRNA and in enzyme activity, but a more detailed analysis has been reported previously[5,9,10]. We conclude from the coincidence of the calculated and the experimentally derived data that the timing of flavonoid glycoside accumulation in UV-irradiated parsley cells is determined solely, or at least predominantly, by the kinetics of gene transcription. It is impossible, however, to deduce from our present data whether one particular enzyme of the two UV light-induced pathways is rate-limiting. Although PAL transcription follows different kinetics from CHS transcription, the apparent half lives of PAL and CHS mRNA and enzyme activities are also different[5], resulting in a similar flavonoid accumulation curve when PAL rather than CHS is used for the calculations described above.

Table 1 UV light-induced *in vivo* PAL and CHS mRNA

Time of labelling	Total RNA used (c.p.m.)	PAL		CHS	
		c.p.m.*	p.p.m.	•c.p.m.*	p.p.m.
−1–0 h	430,000	4	9	1	0
3–4 h	560,000	17	30	76	136
8–9 h	410,000	6	15	16	39

At the indicated times before or after the onset of 2.5 h UV irradiation, cell cultures were concentrated from 5 g per 40 ml to 5 g per 5 ml medium by gentle filtration and labelled for 1 h with 0.5 mCi each of [5,6-^{3}H]uridine (40–60 Ci $mmol^{-1}$), [5-^{3}H]cytosine (25–30 Ci $mmol^{-1}$) and [5′-^{3}H]guanosine (20–40 Ci $mmol^{-1}$). The cells were collected by suction filtration, washed with sterile water and frozen in liquid nitrogen. Polyribosomal RNA and poly(A)$^+$ RNA were isolated from the cells as described previously[9]. The poly(A)$^+$ RNA (specific activity 35,000–70,000 c.p.m. per μg RNA) was hybridized to DBM filters containing 200 ng of the appropriate cDNA insert. Hybridization, washes and release of selected RNAs were as described in Fig. 1 legend. Specific hybridization was determined by subtracting background hybridization to a filter containing 200 ng of λ dV DNA, which gave a mean value of 15 c.p.m. Specific hybridization is also presented as p.p.m. of the input RNA. dV = defective virulent.

* Corrected for non-specific hybridization.

We have recently shown that either the same or very similar PAL and 4CL mRNAs were induced by treatment of parsley cells with UV light or with a fungal elicitor[10]. We therefore measured the transcription rates *in vitro* of the PAL and 4CL genes in nuclei isolated from elicitor-treated cells (Fig. 3). In agreement with observations at the level of changes in amounts of mRNA[10], apparent differential rates of PAL and 4CL gene transcription in elicitor-treated cells were observed, and the elicitor-induced changes in the transcription rate of the 4CL gene were transient but more rapid than those induced by UV irradiation. The transcription rate of a mRNA constitutively expressed in other conditions and monitored with the cDNA insert from pLF14 (see above) declined slowly after elicitor treatment from 20 p.p.m. to 10 p.p.m. within the period of the experiment. Flavonoids are not synthesized in elicitor-treated cells, and the elicitor has no effect on CHS[6].

The relatively high rate of 4CL gene transcription and the low initial rate of PAL gene transcription in elicitor-treated cells, as compared with UV-irradiated cells, are consistent with similar relative levels of both the enzyme activities and the mRNA levels[6,10]. As discussed elsewhere[10], the apparent late and large increase in the transcription rate of the PAL gene and the corresponding accumulation of PAL, or PAL-like, mRNA in elicitor-treated cells are unexpected in view of the rapid, transient changes in the translational activity of PAL mRNA and might be due in part to cross-hybridization of the PAL cDNA with other elicitor-induced mRNA(s) of similar size. The actual changes in the rate of PAL gene transcription responsible for the coordination of the PAL and 4CL mRNA and enzyme activity changes[6,10] might follow a time course similar to that indicated by the dotted line in Fig. 3. Experiments are in progress to clarify this point. In any case, we have shown here for the first time that both types of stress, UV light or pathogen-derived elicitor, induce the respective defence response of the challenged plant cells by transcriptional control of genes involved in the biosynthesis of resistance-related compounds.

We thank Ms G. Braun for technical assistance, Dr G. Feix for cloned maize rDNA and Dr E. Schäfer for valuable help with the mathematical calculations. The work was supported by the Deutsche Forschungsgemeinschaft (SFB 46), the Fonds der Chemischen Industrie, and the Max-Planck-Society.

Inhibition of mRNA binding to ribosomes by localized activation of dsRNA-dependent protein kinase

Arrigo De Benedetti & Corrado Baglioni

Department of Biological Sciences, State University of New York at Albany, Albany, New York 12222, USA

The initiation of protein synthesis can be regulated in mammalian cells by protein kinases which phosphorylate the α subunit of initiation factor eIF-2 (ref. 1). This phosphorylation results in a block in the recycling of eIF-2 (refs 2, 3) and in the inhibition of messenger RNA binding to 80S initiation complexes[4,5]. After eIF-2α is phosphorylated, the mRNA becomes associated with 48S complexes consisting of a 40S ribosomal subunit[4], eIF-2(αP), GDP and Met-tRNA$_f$ (ref. 5). One of the eIF-2α kinases is activated by low concentrations of double-stranded RNA (dsRNA)[6]. This kinase (PK$_{ds}$) is present at a basal level in all mammalian cells investigated[7] and its synthesis is induced in cells treated with interferon[8]. The PK$_{ds}$ may be involved in the inhibition of translation of viral mRNA in interferon-treated cells infected with RNA viruses, as it is activated by viral replicative complexes. It is not known, however, if the activated PK$_{ds}$ preferentially inhibits the translation of viral mRNA when cellular protein synthesis proceeds at a normal rate in infected cells[9]. We now report that mRNA covalently linked to dsRNA is preferentially inhibited from binding to 80S complexes by a localized activation of PK$_{ds}$. This suggests that in interferon-treated cells the binding of some nascent viral mRNAs to functional initiation complexes may be preferentially inhibited by a similar mechanism.

The initial experiments were carried out with ^{3}H-uridine-labelled mRNA from[5] vesicular stomatitis virus (VSV). This was purified by absorption to nitrocellulose filters to obtain mRNA with poly(A) sequences longer than 60 nucleotides[10]. This mRNA was incubated with reticulocyte lysate to determine its binding to initiation complexes, which were fractionated by centrifugation on sucrose gradients[5]. After incubation at 0 °C, unbound mRNA sedimented more slowly than 40S ribosomal subunits (Fig. 1*a*), whereas after incubation at 30 °C the mRNA was quantitatively bound to 80S initiation complexes (Fig. 1*b*). Further addition of ribosomes to 80S complexes was prevented by the inclusion of emetine, an inhibitor of elongation[5]. When the lysate was incubated with 750 ng ml^{-1} of the dsRNA poly(A). poly(U) for 7 min before the addition of VSV mRNA, the assembly of 80S complexes was inhibited and the mRNA sedimented instead at 48S (Fig. 1*c*). When the mRNA and dsRNA were added together, however, most of the mRNA bound to 80S complexes (Fig. 1*d*). This finding could be explained by the observation that it takes up to 5 min after the addition of dsRNA to obtain extensive phosphorylation of eIF-2 (refs 5, 11). The mRNA could bind to 80S complexes within 90 s[12], before a significant fraction of eIF-2 was phosphorylated.

A completely different result was obtained when the dsRNA was covalently linked to mRNA. This dsRNA was formed by annealing poly(U) to the poly(A) sequence of VSV mRNA, as previously described[13], to form dsRNA longer than 60 base pairs which can activate the PK$_{ds}$ (ref. 14). The mRNA containing poly(A)·poly(U) did not bind to 80S initiation complexes, but sedimented instead at 48S (Fig. 1*e*). In this experiment, the poly(A)·poly(U) linked to mRNA was present at the same concetration as 'free' poly(A)·poly(U) in the experiment shown in Fig. 1*d*. The dsRNA linked to mRNA was apparently responsible for inhibiting its binding to 80S initiation complexes. This may have been due to a localized activation of the eIF-2 kinase by the poly(A)·poly(U) in mRNA and the phosphorylation of a fraction of eIF-2 which became associated with this mRNA in 48S complexes. In support of this explanation, when 2-aminopurine, an inhibitor of the eIF-2α kinase[5,6] was added to a binding assay of mRNA containing the poly(A)·poly(U) duplex, the mRNA bound quantitatively to 80S complexes (Fig. 1*f*).

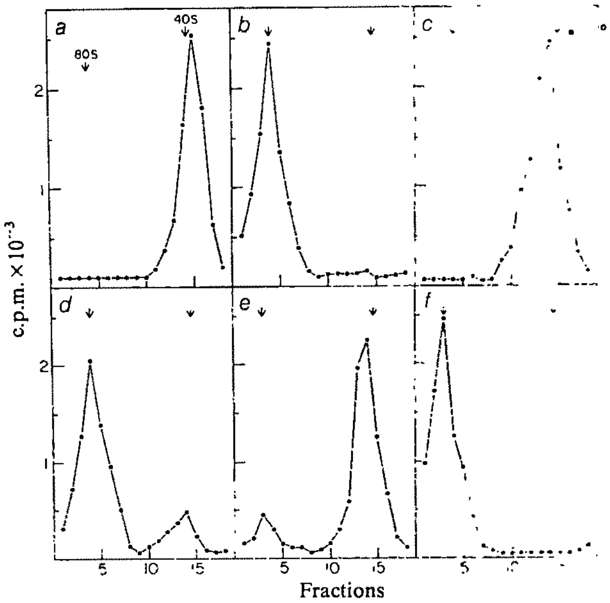

Fig. 1 Binding of VSV mRNA to initiation complexes. *a*, Incubation was at 0 °C. All the other incubations were at 30 °C and were stopped 3 min after the addition of mRNA. The ^{3}H-mRNA was added after a 7-min preincubation without (*b*) or with 750 ng ml^{-1} of poly(A)·poly(U) (*c*). This dsRNA was added together with ^{3}H-mRNA in *d*. The mRNA contained a poly(A)·poly(U) duplex in *e* and *f*; 10 mM 2-aminopurine was added in *f*. The position of the 80S and 40S peaks is indicated by arrows. The VSV mRNA was labelled with ^{3}H-uridine in infected cells, fractionated to obtain a 12–16S fraction[5] and absorbed to nitrocellulose filters to select mRNA with poly(A) sequences longer than 60 nucleotides[10]. This mRNA was either directly used in binding assays or annealed with sufficient poly(U) to prevent its retention by oligo(dT)–cellulose[13]. The average size of the poly(U) (purchased from Miles Biochemicals) was 120 nucleotides. The binding assays were carried out in 0.1 ml reactions which contained 60 µl of reticulocyte lysate supplemented with 50 µM haemin, 10,000 c.p.m. of ^{3}H-mRNA, 0.1 mM emetine and the other additions described elsewhere[5]. At the end of the incubation the assays were diluted with 3 vol of 0.5 M NaCl, 30 mM Mg(OAc)$_2$ and 20 mM Tris, *p*H 7.6 (buffer A) and centrifuged for 5 h at 38,000 r.p.m. through 12-ml gradients of 15–30% sucrose in buffer A. The gradient fractions were counted directly[5].

Figure 2 presents direct evidence for the activation of eIF-2α kinase by dsRNA linked to mRNA. Lysate was incubated with [γ-^{32}P]ATP and 750 ng ml^{-1} of free poly(A)·poly(U) or mRNA-linked poly(A)·poly(U). With no added dsRNA or after 3 min incubation with free poly(A)·poly(U), there was no detectable eIF-2α phosphorylation (Fig. 2*a*, *b*). After 7 min of incubation with poly(A)·poly(U) or 3 min incubation with mRNA-linked poly(A)·poly(U), eIF-2α was clearly phosphorylated (Fig. 2*c*, *d*). When 48S complexes were isolated and analysed by gel electrophoresis[5], some eIF-2(αP) was found associated with these complexes (Fig. 2*e*, *f*). It appeared that eIF-2α was phosphorylated at a faster rate with mRNA-linked poly(A)·poly(U) than with free poly(A)·poly(U). This could be explained by a slow rate of dephosphorylation of eIF-2(αP) bound to 48S complexes relative to unbound eIF 2(αP)[15]. In one incubation, the PK$_{ds}$ bound to mRNA-linked poly(A)·poly(U) preferentially phosphorylated eIF-2α associated with 48S complexes, whereas in the other the PK$_{ds}$ bound to free poly(A)·poly(U) phosphorylated eIF-2α which could be readily dephosphorylated by lysate phosphatases[15]. In fact, a 70,000 molecular weight polypeptide previously identified[16] with PK$_{ds}$ was detected in 48S complexes isolated from the incubation with mRNA-linked poly(A)·poly(U) (Fig. 2*f*). This polypeptide could represent PK$_{ds}$ bound to the 3'-terminal duplex of mRNA in these complexes.

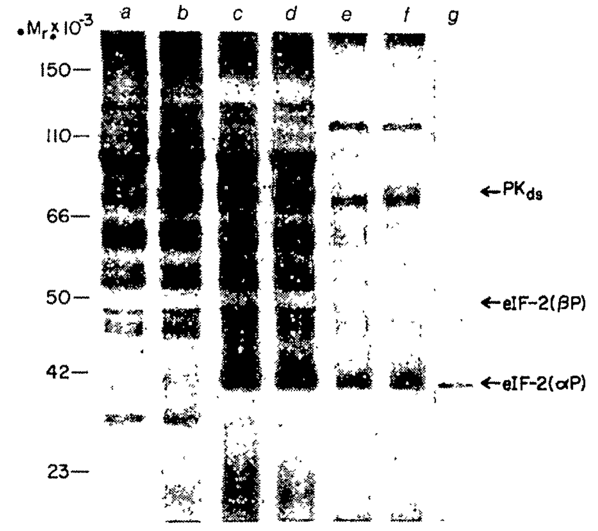

Fig. 2 Electrophoretic analysis of the phosphoproteins labelled: *a*, in 7 min incubation with no added dsRNA; *b*, *c*, in 3 and 7 min with 750 ng ml^{-1} of poly(A)·poly(U); *d*, in 3 min with mRNA annealed to poly(U) as described in Fig. 1*e* (750 ng ml^{-1} of dsRNA). The incubations were assembled as in Fig. 1, except that ATP was substituted with 10 μCi of [γ-^{32}P]ATP; 20 μl of each reaction were directly analysed (*a*–*d*), whereas 80 μl of the incubations shown in *c* and *d* were fractionated by gradient sedimentation to isolate the 48S peak. Gradient fractions were combined and proteins precipitated with 2 vol of acetone (*e*, *f*). The proteins were fractionated on 10% polyacrylamide–0.26% bisacrylamide gels. Authentic eIF-2 phosphorylated in a separate reaction is shown in *g*. To activate eIF-2 kinase, reticulocyte lysate was incubated for 15 min without added haemin[6]; 3 μl of this lysate were incubated for 4 min with 2 μg of purified eIF-2 (a gift of Dr William C. Merrick), 50 μM (γ-^{32}P]ATP (1 μCi), 15 μg of bovine serum albumin and 1.5 mM Mg(OAc)$_2$. 0.2 μg of eIF-2 were analysed. The position of the PK$_{ds}$, eIF-2(αP), eIF-2(βP) and molecular weight markers is indicated.

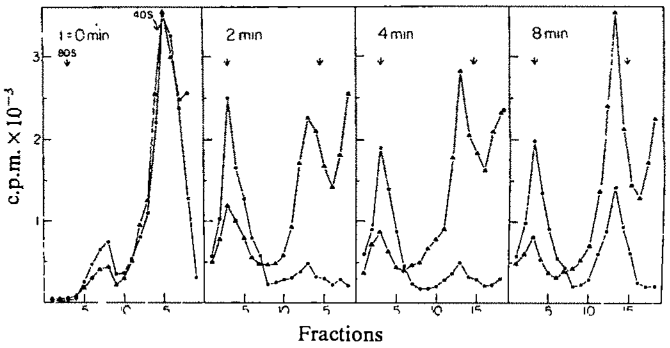

Fig. 3 Binding of HeLa cell mRNA to initiation complexes. Each 0.1-ml binding assay contained 17,500 c.p.m. of ^{3}H-mRNA (●) and ^{32}P-mRNA (▲) with a poly(A)·poly(U) duplex. The reactions were incubated at 30 °C for the time indicated in the panel and analysed as described in Fig. 1 legend, except that the gradient pellets containing polyribosomes were also counted. The ratio of c.p.m. in polyribosomes and 80S initiation complexes over c.p.m. in 48S complexes was 8.6, 6.7 and 2.5 for the ^{3}H-mRNA, and 0.7, 0.4 and 0.3 for the ^{32}P-mRNA at 2, 4 and 8 min, respectively. The ^{3}H-mRNA (58,000 c.p.m. per μg) was obtained from HeLa cells labelled with ^{3}H-uridine[13] and the ^{32}P-mRNA by annealing 200 ng of unlabelled HeLa cells mRNA with 2 ng of poly(U) labelled by 3′-terminal addition of [γ-^{32}P]dATP. In a 2-μl reaction, 200 ng of poly(U) were incubated for 4 h with 50 μM (α-^{32}P]dATP (150 μCi), 2.5 U of calf thymus deoxynucleotide terminal transferase and 0.5 μg of bovine serum albumin in 0.2 M K-cacodylate, 2 mM dithiothreitol, 0.5 mM CoCl$_2$ and 25 mM Tris, *p*H 6.9 (ref. 17). The reaction was stopped by the addition of 0.1 ml of NaOAc buffer, *p*H 5.2, containing 5 μg of yeast tRNA. The RNA was precipitated with 0.4 ml of 3% cetyltrimethylammonium bromide, washed with this solution and 75% ethanol, and dissolved in 0.125 M KOAc and 20 mM HEPES buffer, *p*H 7.4. The poly(U) had a specific activity of 1.3 × 10^5 c.p.m. per ng and the specific activity of the mRNA annealed with this poly(U) was ~1 × 10^4 c.p.m. per ng.

In subsequent experiments, we demonstrated a preferential inhibition of the initiation of mRNA containing a poly(A)·poly(U) duplex by including in the same incubation mRNA not annealed with poly(A)·poly(U) and labelled with a different isotope. In these experiments, poly(U) was labelled to high specific activity with terminal transferase[17] and annealed with unlabelled HeLa cell mRNA (Fig. 3). Only the mRNA containing a poly(A)·poly(U) duplex was thus labelled with ^{32}P. Very small amounts of this mRNA were added to binding assays together with uniformly ^{3}H-labelled HeLa mRNA. The concentration of added dsRNA was reduced to 3 ng ml^{-1} to delay the generalized inhibition of initiation observed in the experiment shown in Fig. 1*c*. Therefore, we carried out the binding assays without added emetine and allowed multiple cycles of initiation to take place. When an incubation was kept at 0 °C, the two mRNAs sedimented more slowly than 40S ribosomal subunits (Fig. 3*a*). The ^{3}H-mRNA was bound to 80S initiation complexes and to polyribosomes after 2–8 min incubation at 30 °C, whereas the mRNA containing the poly(A)·poly(U) duplex sedimented predominantly at 48S (Fig. 2*b*–*d*). The ratio of ^{3}H-mRNA bound to polyribosomes and 80S complexes to that sedimenting at 48S was always much greater than that of the ^{32}P–mRNA with the poly(A)·poly(U) duplex. It should be pointed out that even with as little as 3 ng ml^{-1} of dsRNA, the initiation of protein synthesis was inhibited after 8 min of incubation[6] and a significant fraction of ^{3}H-mRNA sedimented in 48S complexes.

To demonstrate that the inhibition of binding of this mRNA was caused by the activation of PK$_{ds}$, a binding assay was performed using a high concentration of added dsRNA, thus specifically preventing the activation of this kinase[6]. When HeLa cell mRNA annealed with labelled poly(U) was incubated with lysate, its binding to 80S initiation complexes was inhibited (Fig. 4*a*). With 10 μg ml^{-1} of poly(I)·poly(C) present, however, this mRNA was quantitatively bound to 80S complexes (Fig. 4*b*). Two other experiments provided additional evidence that the inhibition of binding of mRNA covalently linked to dsRNA required the activation of PK$_{ds}$. A mRNA containing a hybrid poly(A)·poly(dT) duplex was quantitatively bound to 80S initiation complexes (Fig. 4*c*). This showed that an RNA/DNA duplex, which could not activate the PK$_{ds}$ (ref. 18), had no effect on mRNA binding. Another experiment, based on the observation that 50 μM ethidium bromide prevented the activation of PK$_{ds}$ by poly(A)·poly(U) (ref. 19), showed that the inhibition of binding of mRNA with the poly(A)·(U) duplex was largely abolished by adding this concentration of ethidium bromide to a binding assay (Fig. 4*d*).

The inhibition of binding of mRNAs covalently linked to dsRNA was discovered with model polynucleotides constructed for the present experiments. The mechanism involved in this inhibition, however, is of general interest as it may function in interferon-treated cells preferentially to inhibit translation of viral mRNA. This mechanism involves the activation of PK$_{ds}$, the phosphorylation of eIF-2α and the binding of mRNA and eIF-2(αP) to 48S complexes. In the experiments with two mRNAs labelled with different isotopes present in the same incubation, only the binding of mRNA linked to dsRNA was inhibited. Therefore, eIF-2(αP) presumably associated with mRNA close to the site of activation of PK$_{ds}$. This could result from the binding of this kinase to the mRNA-linked poly(A)·poly(U) and the phosphorylation of eIF-2 interacting with this mRNA during the formation of 48S initiation complexes. The association of eIF-2 with specific nucleotide sequences near the 5′-terminus of mRNA has been reported[20], but it is not known whether these sequences interact with eIF-2 already bound to 40S ribosomal subunits during the assembly of initiation complexes.

On addition of 2-aminopurine and dephosphorylation of eIF-

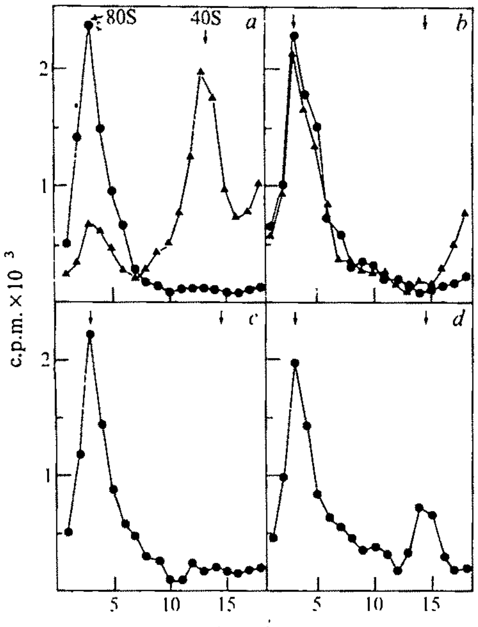

Fig. 4 Binding of HeLa cell mRNA to initiation complexes. The binding was carried out for 3 min after the addition of mRNA and analysed as described in Fig. 1 legend. The assays were incubated for 7 min without (a) or with (b) 10 μg ml^{-1} of poly(I)·poly(C) before the addition of 10,000 c.p.m. of HeLa cell ^{3}H-mRNA (●) and of mRNA containing a poly(A)·(U) duplex labelled with ^{32}P (▲) as described in Fig. 3 legend. The other assays contained mRNA with a poly(A)·poly(dT) duplex (c) or with a poly(A)·poly(U) duplex (d). Poly(dT) and poly(U) were labelled with terminal transferase as described in Fig. 3 legend, except that 2 μg of polynucleotide and 10 μCi of ^{3}H-dCTP were used. The polynucleotides were labelled to a specific activity of 5×10^3 c.p.m. per ng and 10 ng were annealed with 1 μg of HeLa cell mRNA. 50 μM ethidium bromide was added to the binding assay in d.

2(αP) by phosphatases[21], the mRNA binds slowly to 80S initiation complexes[5], indicating that mRNA in 48S complexes is not inactivated. It seems possible that mRNA synthesized by viral replicative complexes which activate the PK$_{ds}$ becomes bound to 48S complexes. Comparison of the rate of cleavage of mRNA in polyribosomes with that of mRNA associated with 48S complexes shows that the latter is cleaved significantly faster by the endonuclease activated by 2′,5′-oligo(A) (ref. 15). As these oligonucleotides may be synthesized by an interferon-induced enzyme bound to viral replicative complexes[22] and can activate the endonuclease in a localized way[13], it seems possible that mRNA in 48S complexes formed during transcirption of viral templates is preferentially degraded. Experiments are in progress to investigate this in intact cells. It is also conceivable that PK$_{ds}$ is involved in translational control of cellular mRNA if duplexes which can activate this kinase are formed.

We thank Drs Connie R. Faltynek and Timothy W. Nilsen for discussions and criticism of this manuscript, and Dr William C. Merrick for the gift of purified eIF-2. This work was supported by American Cancer Society grant CD-103, and NIH grants CA29895 and AI16076.

Activating protein factor binds *in vitro* to upstream control sequences in heat shock gene chromatin

Carl Wu

Laboratory of Biochemistry, Developmental Biochemistry Section,
National Cancer Institute, National Institutes of Health, Bethesda,
Maryland 20205, USA

DNA sequences, important for the control of *Drosophila* heat shock gene expression, are packaged in chromatin in a nuclease hypersensitive configuration[1]. Recently, two protein-binding (exonuclease-resistant) sites which cover the TATA box sequence and an upstream control element were shown to occur *in vivo* amidst the 5′ terminal hypersensitive regions of several heat shock genes[2]. Protein-binding at the TATA box is independent of heat shock, but the binding at the upstream element is heat shock dependent, and it was proposed that a heat shock activator protein, HAP, positively regulates the genes[2]. Here, I report the detection of HAP activity in heat shocked cell extracts by reconstituting specific binding to *hsp*82 gene chromatin *in vitro*. Inhibition of the binding by free DNA from the 5′ region of heat shock genes implies a coordinate regulation of the gene family through HAP interaction with the upstream heat shock consensus sequence[3]. Furthermore, the special ease of induction of the *hsp*82 gene over other heat shock genes can be explained in molecular terms by the higher affinity of HAP for the *hsp*82 binding site, which contains a 28 base sequence with almost perfect dyad symmetry, GAAGCCTCTAGAAG|TTTCTAGAGACTTC.

We reasoned that promoter DNA in its naturally 'hypersensitive' state in chromatin should be a superior substrate to purified DNA for the *in vitro* binding of specific protein factors extracted from *Drosophila* cell nuclei. The binding to the target in chromatin can be revealed by the resistance to exonuclease digestion starting at an appropriate restriction endonuclease cut in the 5′ hypersensitive region. We chose to monitor the binding activity of heat shocked cell extracts on the single-copy gene encoding the heat shock protein of molecular weight 81,858 (ref. 4–8) (*hsp*82; formerly referred to as *hsp*83), because of the exceptionally strong resistance to exonuclease digestion observed previously *in vivo*[2]; for experimental strategy, see Fig. 1.

The *in vivo* binding of HAP factor to the *hsp*82 gene promoter in heat shocked *Drosophila* embryos is shown in Fig. 2. Purified nuclei from normal (lane a) or heat shocked (lanes b, c) embryos were digested with *Eco*RI and an exhaustive amount of *Escherichia coli* exonuclease III (exoIII). (ExoIII is unable to proceed with digestion from fragment ends made by those restriction enzymes, for example *Pst*I, which leave a 4-base, 3′ protrusion; S. Henikoff, personal communication.) DNA was purified and the single-stranded DNA tails were trimmed with S$_1$ nuclease. After repurification, the DNA was cut with two restriction enzymes, *Xho*I and *Hin*dIII, and was sized by electrophoresis on agarose gels. The *hsp*82 gene fragments resulting from *Eco*RI and exonuclease digestion were visualized with an indirect end-labelling probe after Southern transfer. Thus, the barrier to exonuclease digestion downstream from the *Eco*RI cut in the active gene was located at position −86, the distal border of the HAP binding site (Fig. 2, lanes b, c) whilst that

Fig. 1 The *in vitro*, chromatin binding assay. The nuclease hypersensitive site in the noninduced *hsp*82 gene 5′ region is represented as a stretch of DNA associated with the TATA box binding protein, (TAB)[2]. Circles represent neighbouring nucleosomes whose precise positions have not been determined. HAP (+) and HAP (−) refer to the heat shocked and nonshocked condition, respectively.

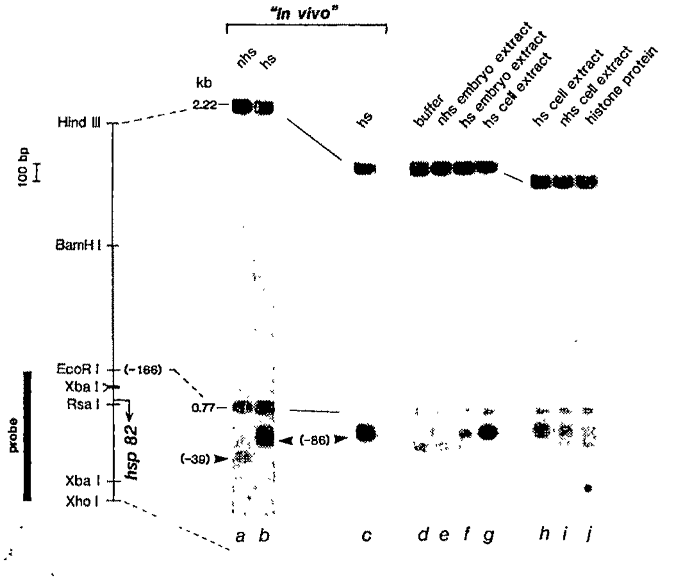
at position −39 in the inactive gene reveals a boundary of the TATA box binding protein (TAB) (lane *a*)[2].

To assay for HAP factor *in vitro*, nuclei purified from non-heat-shocked *Drosophila* embryos were incubated with a 0.4 M NaCl extract of nuclei from heat-shocked embryos or cultured cells (Schneider line 2, SL2). After incubation with the extract, the nuclei were pelleted and resuspended for digestion with *Eco*RI and exoIII, and the exonuclease-resistant sites were mapped as above. When using buffer alone, or an extract from non-heat-shocked embryos, or when histone H1 protein was used for the incubation, no resistance at position −86 was observed. However, distinct resistance at −86 was observed using extracts from heat-shocked embryos, and from two preparations of shocked SL2 cells. We are thus able to detect HAP binding *in vitro* using crude nuclear extracts without having to resort to previous purification.

HAP binding activity in shocked embryonic extracts is low compared to that observed in shocked SL2 cell extracts; this is

Fig. 2 Chromatin binding activity of extracted factors at the *hsp*82 gene promoter. *a–c*, exoIII digestion downstream from an *Eco*RI cut at position −166 in chromatin from non-heat-shocked (nhs) *Drosophila* embryos, and from embryos heat-shocked (hs) at 36 °C for 15 min. (+1) is the transcriptional start indicated on the partial restriction map by the arrow pointed in the direction of transcription. Arrowheads indicate the positions of the barriers to exoIII digestion. Purified nuclei from 2–7-h-old *D. melanogaster* (Oregon R) embryos were digested with *Eco*RI and exoIII; the DNA was purified, trimmed with S_1 nuclease, repurified, digested with *Hin*dIII and *Xho*I, electrophoresed, blotted to nitrocellulose and hybridized with an indirect end-labelling probe (solid bar) as described previously[2]. *c*, From the same gel as *d–j*. *d–j*, exoII digestion from the *Eco*RI cut at position −166 in normal chromatin incubated with the indicated extracts and reagents.

Methods: Nuclei were purified from 2–7-h-old *Drosophila* embryos grown at 24 °C as previously described[2]. The pelleted nuclei were resuspended in nuclear buffer[2] at 5×10^8 per ml, transferred to 1.5 ml Eppendorf tubes and centrifuged briefly in the microfuge. After removal of the supernatant, the pellet was resuspended in buffer alone (Solution III; see below), in extract plus 5 mM $MgCl_2$, or in 50 μg histone HI protein (Boehringer–Mannheim) per ml of nuclear buffer, and incubated at room temperature, 24 °C, for 20 min. The nuclei were pelleted again and the supernatant was removed. Nuclei were then resuspended for digestion at 30 °C for 15 min in nuclear buffer—5% glycerol containing 3,500–6,100 U ml^{-1} *Eco*RI and 9,000 U ml^{-1} *E. coli* exonuclease III and $MgCl_2$ adjusted to 6 mM. The reactions were terminated with EDTA and SDS, and nucleic acids were purified by organic extraction and precipitated in EtOH. S_1 nuclease trimming of ssDNA tails was performed essentially as described[2], using 2,500 U ml^{-1} S_1 nuclease for a DNA concentration of ~0.1 mg ml^{-1}. DNA was repurified and digested with *Hin*dIII and *Xho*I, electrophoresed on a 25 cm long 1.4% agarose Tris-acetate EDTA (TAE) gel, blotted to nitrocellulose and hybridized as above. Extracts were prepared using a modification of the procedure of Dignam *et al.*[21]. Schneider line 2 tissue culture cells were grown in suspension[22] at 23–24 °C, to a density of 5×10^6–1×10^6 cells ml^{-1}. After washing in saline, pelleted cells were frozen in dry ice-EtOH and stored at −70 °C until use. Pellets containing about 10^{10} cells were thawed, and resuspended at 4 °C, the subsequent operating temperature, in two packed cell volumes of Solution I (0.3 M sucrose, 10 mM HEPES, *p*H 7.9, 10 mM KCl, 1.5 mM $MgCl_2$, 0.1 mM EGTA, 0.5 mM dithiothreitol (DTT), 0.5 mM phenylmethanesulphonyl fluoride (PMSF).) Cells were lysed in a Dounce homogenizer using about 15 strokes of the tight pestle. Breakage of cells was about 95% by microscopic inspection. The homogenate was centrifuged in a clinical centrifuge at top speed for 7.5 min (1,600*g*) to pellet crude nuclei. The nuclei were resuspended in 2 packed nuclei volumes of Solution II (10 mM HEPES, *p*H 7.9, 400 mM NaCl, 1.5 mM $MgCl_2$, 0.1 mM EGTA, 0.5 mM DTT, 5% glycerol, 0.5 mM PMSF) and the final NaCl concentration was re-adjusted to 0.4 M. The crude nuclei were extracted at 4 °C for 30 min with continuous stirring, followed by centrifugation at 100,000*g* for 1 h. The supernatant was transferred into a colloidon bag (Schleicher and Schuell UH 100/10) for dialysis in Solution III (20 mM HEPES, *p*H 7.9, 75 mM NaCl, 0.1 mM EDTA, 0.5 mM DTT, 20% glycerol, 0.5 mM PMSF) for about 5 h. A vacuum was applied for some time during dialysis to concentrate the extract to the original packed cell volume. The extract was cleared by centrifugation at 10,000*g* for 10 min. The supernatant (~50 mg protein per 10^{10} cells) was frozen in aliquots in liquid N_2, and stored at −70 °C; the extracts retained their activity for at least two months after storage. A 1/5 dilution of active extract still gave 'full' occupancy of the binding site, but further dilutions up to 1/40 reduced binding activity to undetectable levels. Embryonic extracts from 15 g each of normal and heat shocked (36 °C, 20 min) 0–18-h-old *Drosophila* embryos were prepared from nuclei purified by centrifugation through Solution I (1.7 M sucrose) as described previously[2] except that the homogenizing buffer was Solution I supplemented with leupeptin, 5 μg ml^{-1}, pepsfatin, 2 μg ml^{-1}, and aprotinin, 0.2 TI U ml^{-1}. Embryonic nuclei were extracted for 30 min at 4 °C, with stirring, in 10 ml Solution II; NaCl was re-adjusted to 0.4 M to account for the volume of the purified nuclear pellet. The embryonic extract was centrifuged, dialysed, clarified and stored essentially as for extracts from cultured SL2 cells.



presumably due to high protease activity associated with the former. A non-heat-shocked SL2 cell extract also contains HAP binding activity (Fig. 2, lane *i*) (roughly 20-fold less than shocked cell extracts, as seen by dilution experiments, data not shown). This result is not unexpected as the *hsp*82 gene is expressed at some level in *Drosophila* cell lines cultured under normal laboratory conditions[6,9–11] and as HAP binding *in vivo* can be observed even in nonshocked SL2 cells (C.W., unpublished observations).

To map the proximal boundary of HAP binding *in vitro* we analysed the resistance to exonuclease digestion upstream from a *Rsa*I cut at position +20 in the chromatin (Fig. 3). As shown previously[2], the weaker *in vivo* exonuclease resistance of the non-heat-shocked *hsp*82 gene at position −17, the proximal border of the TAB binding site, is largely overcome in limit-digestion conditions, and the bulk of the *Rsa*I-cleaved fragments are further degraded to a smear (not well reproduced in Fig. 3, lane *b*). On heat shock (lane *c*), HAP binding poses an impenetrable barrier at position −50, and also retards the kinetics of digestion through the TAB site. When non-heat-shocked nuclei are incubated with the indicated extracts, pelleted, and resuspended for digestion with *Rsa*I and exoIII, the position of resistance to exoIII generated by *in vitro* HAP binding is identical to that shown *in vivo* (Fig. 3, lanes *d–i*). The specific variation in the binding activity of the extracts from embryos and cultured cells also parallels the analysis of exonuclease resistance from the *Eco*RI cut in Fig. 2.

We can assay for this binding independently by measuring the sensitivity to *Xba*I cleavage in chromatin at two sites positioned at −74 and −64, within the HAP binding site. When non-heat-shocked embryonic nuclei are incubated with the extract from heat-shocked SL2 cells, the *Xba*I sites at positions −74 and −64 are clearly protected from cleavage (Fig. 3, lane *m*). Interestingly, the other *Xba*I site at position +484, inside the *hsp*82 transcriptional unit, does not become more sensitive upon shock as it does *in vivo*, suggesting that the extract may be unable to effect the secondary phenomenon associated with chromatin activation.

The chromatin binding activity is unaffected by treatment of active extract with RNase A+T1, or with micrococcal nuclease. However, when extracts are treated with trypsin or proteinase K (subsequently inactivated with protease inhibitors), HAP binding activity is abolished using the exonuclease protection

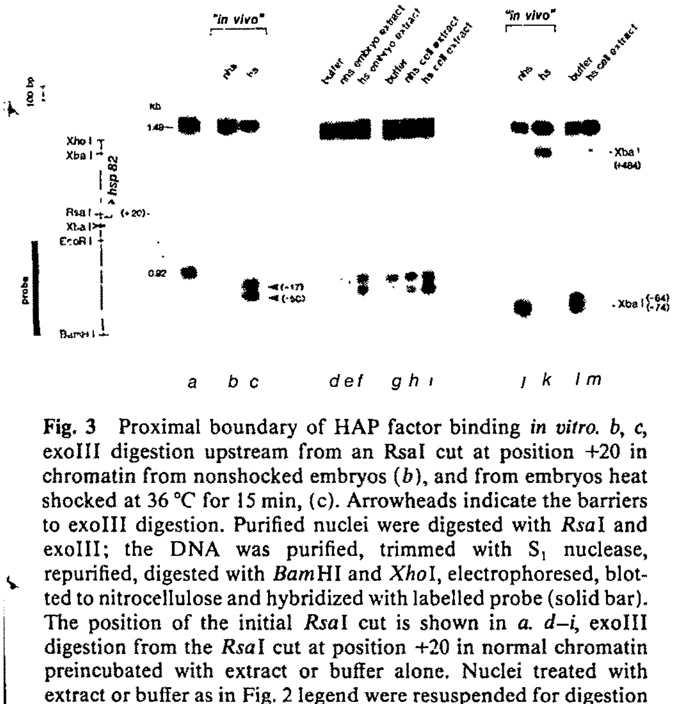


Fig. 3 Proximal boundary of HAP factor binding *in vitro*. *b*, *c*, exoIII digestion upstream from an RsaI cut at position +20 in chromatin from nonshocked embryos (*b*), and from embryos heat shocked at 36 °C for 15 min, (c). Arrowheads indicate the barriers to exoIII digestion. Purified nuclei were digested with *Rsa*I and exoIII; the DNA was purified, trimmed with S_1 nuclease, repurified, digested with *Bam*HI and *Xho*I, electrophoresed, blotted to nitrocellulose and hybridized with labelled probe (solid bar). The position of the initial *Rsa*I cut is shown in *a*. *d–i*, exoIII digestion from the *Rsa*I cut at position +20 in normal chromatin preincubated with extract or buffer alone. Nuclei treated with extract or buffer as in Fig. 2 legend were resuspended for digestion at 35 °C for 12 min in nuclear buffer-5% glycerol containing 1,300 U ml^{-1} *Rsa*I plus 9,000 U mol^{-1} exoIII (*d–f*), or 2,300 U ml^{-1} *Rsa*I plus 9,000 U ml^{-1} *exo*III (*g–i*). The reactions were stopped, the purified DNA treated with S_1 nuclease, repurified, restricted with *Bam*HI and *Xho*I, electrophoresed on a 40-cm-long TAE agarose gel, blotted to nitrocellulose and hybridized as above. *j–m*, *Xba*I sensitivity of the *hsp*82 gene at positions −64, −74 and +484 in chromatin from nonshocked embryos (*j*), from embryos heat shocked at 36 °C for 15 min (*k*), and in nonshocked embryonic chromatin incubated with buffer alone (*l*), or with an extract made from heat shocked SL2 cells (*m*). Nuclei purified from 2–7-h-old *Drosophila* embryos were digested with 1,400 U ml^{-1} *Xba*I at 35 °C for 15 min (*j*, *k*), and with 1,700 U ml^{-1} *Xba*I at 35 °C for 12 min for the nuclei incubated with buffer or extract (*l*, *m*). DNA was purified and restricted for blot analysis as above.

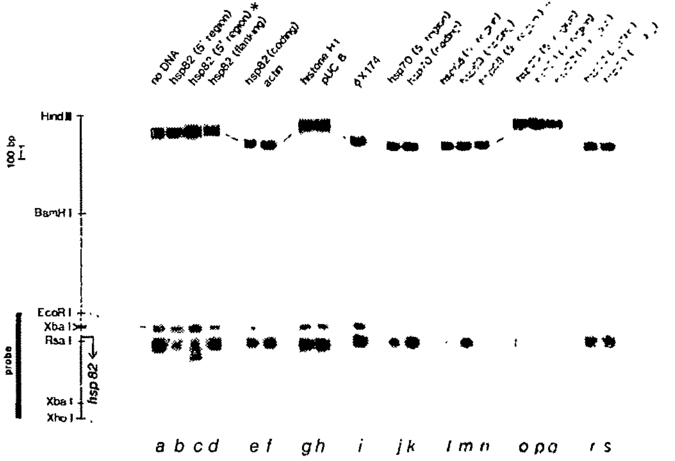

Fig. 4 DNA inhibition of HAP binding to *hsp*82 gene chromatin. Extracts from heat shocked SL2 cells were diluted 5-fold; 100 µl was incubated with the indicated DNA's for 10 min at 24 °C, followed by incubation with nuclei purified from nonshocked *Drosophila* embryos. The DNA templates were linearized by restriction cleavage before incubation. The inhibition produced by different parts of each heat shock gene is compared using approximately equivalent DNA concentrations for the particular sequence Specific chromatin-binding activity was assayed by exonuclease protection as in Fig. 2 legend. *b*, *hsp*82 (5′ region); 0.05 µg of 186 bp, *Eco*RI (−166) to *Rsa*I (+20) fragment, with 0.95 µg of ϕX174-*Hae*III as carrier DNA. *c*, DNA as in (*b*) was incubated with extract as above. $CaCl_2$ was added to 0.4 mM, micrococcal nuclease to 300 U ml^{-1} and free DNA was digested for 5 min at 24 °C. Micrococcal nuclease was inactivated with EGTA to 1 mM and the extract was then incubated with noninduced nuclei as above. *d*, *hsp*82 (flanking); 0.2 µg of 0.7 kb upstream *Bam*HI to *Eco*RI (−166) fragment with carrier DNA as above. *e*, *hsp*82 (coding); 0.25 µg of 1.8 kb *Xho*I (+584) to *Sal*I (+2,400) fragment with carrier DNA as above. *f*, Actin gene; 1 µg of linearized plasmid DNA consisting of pBR322 vector and a 3.8 kb *Bam*HI–*Eco*RI insert containing coding and upstream sequences for the *Drosophila* actin gene at chromosomal locus 57A (E. Fryberg, personal communication). g, Histone HI gene; 0.75 µg of a 1.3 kb *Bam*HI–*Hpa*I fragment containing roughly the 5′ half of the coding sequence plus upstream DNA[23]. *h*, pUC8; 1 µg of the linearized plasmid DNA. *i*, ϕX174; 1 µg of duplex phage DNA cut with *Hae*III. *j*, *hsp*70 (5′ region); 0.4 µg of 279 bp *Xho*I (−194) to *Pst*I (+85) fragment. *k*, *hsp*70 (coding); 1 µg of 1.1 kb *Pst*I (+85) to *Pst*I (+1,187) fragment. *l*, *hsp*68 (5′ region); 1 µg of 0.4 kb upstream *Pst*I to *Hpa*II (+44) fragment[24]. *m*, *hsp*68 (coding); 1 µg of 0.6 kb *Pst*I–*Pst*I fragment of coding sequence[24]. *n*, 1 µg of *hsp*68 0.4 kb 5′ *Pst*I–*Hpa*II fragment was incubated with extract, digested with micrococcal nuclease and processed as in (*c*). *o*, *hsp*26 (5′ region); 1 µg of linearized plasmid DNA consisting of pUC9 vector and a 0.7 kb upstream *Pst*I–*Eco*RI (+7) fragment[25–28]. *p*, *hsp*23 (5′ region); 1 µg of linearized plasmid DNA consisting of pUC9 vector and a 0.7 kb upstream *Pst*I–*Eco*RI (+7) fragment[25–28]. *q*, *hsp*22 (5′ region); 1 µg of linearized plasmid DNA consisting of pUC9 vector and a 0.6 kb *Hin*dIII (−402) to *Hin*dIII (−213) fragment[25–28]. *r*, *hsp*22 (coding); 1 µg of linearized plasmid DNA consisting of pUC9 vector and a 0.8 kb downstream *Bam*HI to *Hin*dIII (+213) fragment[23–28]. *s*, *hsp*26 (coding); 1 µg of linearized plasmid DNA consisting of pUC9 vector and a 0.6 kb downstream *Pvu*II to *Eco*RI (+7) fragment[25–28].

assay as above (data not shown). This confirms that the specific binding component of HAP is protein.

Specific HAP binding to *hsp*82 gene chromatin is almost totally inhibited by pretreating active extracts with a short *hsp*82 DNA fragment containing the binding site (Fig. 4, lane *b*). No inhibition on pretreatment is observed using further upstream flanking sequences or sequences in the *hsp*82 coding region, nor when other DNAs are used (lanes *d*–*i*). On the other hand, purified DNA from the 5′ region of the other heat shock genes: *hsp*70, *hsp*68, *hsp*26, *hsp*23, *hsp*22 do inhibit to a partial extent the binding of HAP factor to *hsp*82 gene chromatin (lanes *j*, *l*, *o*–*q*), whereas purified DNA from the coding sequences of *hsp*70, *hsp*68, *hsp*22 and *hsp*26 do not (lanes *k*, *m*, *r*, *s*). To demonstrate that the HAP activity we have measured in the extract is a primary DNA binding activity and not a secondary enzymatic activity with converts an ineffective HAP to its specific DNA binding mode, we pretreated active extract with target DNA and digested excess DNA with micrococcal nuclease. The resultant extract has no HAP binding activity towards the *hsp*82 gene chromatin (Fig. 4, lanes *c*, *n*); the activity should have been retained were the active component secondary to DNA binding. (Effective removal of excess DNA by micrococcal nuclease is demonstrated by the recovery of HAP binding activity to chromatin on readdition of active extract; data not shown.)

We infer from these inhibition experiments that HAP factor for the *hsp*82 gene is able to bind to purified DNA, not only to its own target sequence but also to the upstream consensus sequence[3] shared by other heat shock genes. The simplest model consistent with the data is that HAP, in concert with bound TAB, can coordinately activate the whole heat shock gene family by binding to each upstream element, and that the variation in the kinetics of activation among these genes reflects differential binding affinities of HAP for individual upstream elements that are similar but not identical in sequence. Such a model would predict a direct relationship between decreasing HAP binding affinities and the increasing order of transcriptional activation. The available evidence supports this prediction. The *hsp*82 gene is most easily activated[6,9–11,12], whilst HAP binding strength *in vivo* (ref. 2 and unpublished data), or *in vitro* (Fig. 4) is greater for the *hsp*82 gene than for other heat shock genes. It will be of interest to investigate further the correlation between binding strength and activation kinetics.

We re-examined the sequence of the 36 bp HAP binding site[2] for *hsp*82 and found that it covers a central 28 base sequence with almost perfect dyad symmetry (24 bases out of 28): (−81) GAAGCCTCTAGAAG|TTTCTAGAGACTTC (−54). None of the upstream elements of the other heat shock genes have this high degree of symmetry. The exceptionally strong binding affinity of HAP to this symmetrical dyad suggests that it may be the canonical recognition sequence for HAP binding (as a protein dimer or tetramer like prokaryotic DNA binding proteins).

We do not believe that HAP is synthesized *de novo* upon heat shock, because the response can be brought on within minutes after stimulation, and can occur in the absence of protein synthesis[13]. It seems that HAP should either be decompartmentalized upon heat shock or more likely, be converted from a pre-existing inactive form to a specific DNA binding form. Our finding that HAP activity in the crude extract binds DNA directly does not preclude the presence of secondary modifying activities in the extract. We are currently devising appropriate assays to retrace the physiological pathway from the terminal events of heat shock.

Others have shown the presence of eukaryotic sequence-specific DNA binding proteins[14,15], and activators of heat shock genes have been reported in studies employing different methods[16–19]. HAP factor appears to be unrelated to these activities. During the preparation of this manuscript, Parker and Topol[20] published a report on a *Drosophila* transcription factor designated HSTF that is specific for the *hsp*70 gene; partially purified preparations of this factor bind to a 55 bp region upstream of the TATA box. HAP and HSTF bind roughly to the same DNA sequence, but their binding activities in non-heat-shocked cells appear to be very different; further work should illuminate the relationship between the two factors.

We believe that the *in vitro* chromatin binding, exonuclease protection assay reported here is a powerful method for analysing eukaryotic DNA binding proteins for the following reasons: (1) precision in delimiting the binding site, (2) confidence in the physiological relevance of the binding provided by *in vivo* comparison, and (3) exceptional sensitivity, as seen by detection of binding activity in crude extracts with no fractionation whatsoever. This feature permits binding activity to be tracked from the start of the purification; at later stages, more traditional assays could be used to increase experimental efficiency.

I thank B. Sauer, C. Klee, P. Wagner and S. Wilson for helpful suggestions on protein analysis, E. Craig, E. Fyrberg, R. Holmgren, R. Blackman, R. Morimoto and M. Meselson for gifts of cloned DNA, T. Paisley for technical assistance and B. Miller for typing the manuscript.

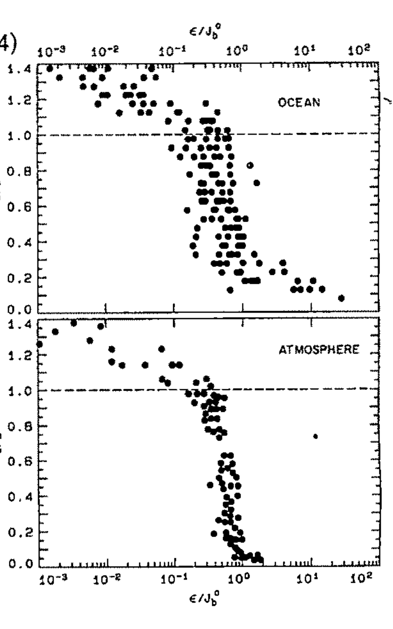
Turbulence in an oceanic convective mixed layer—Corrigendum

T. J. Shay & M. C. Greg

Nature 310, 282–285 (1984)

In the above letter it was stated that the mixed layer mean value of ε/J_b^0 in the ocean was a factor of two lower than that in the atmosphere, and that difference was left unexplained. The difference was the result of a computational error. When that error is corrected, the two cases are in much better agreement, as seen in the figure. For the region $0.4 < z/D < 1.0$, the mean value of ε/J_b^0 in both the ocean and atmosphere is 0.45. The difference in scatter may be due to more restrictive editing of the atmospheric data as well as the influence of lateral processes in the ocean.



Theology *in vitro*

John Habgood

Begotten or Made? By Oliver O'Donovan.
Clarendon: 1984. Pp.88. Pbk £2.50, $4.95.

THE debate sparked off by the Warnock Committee report on human fertilization should benefit from this unusual contribution by Professor O'Donovan. As befits the Regius Professor of Moral and Pastoral Theology in the University of Oxford he approaches the topic at a high level of generality, in sharp contrast to the pragmatic and piecemeal procedure often favoured by practising scientists. He modestly claims to make no more than a contribution to the discussion, but his main argument, if accepted, would radically change the thrust of much current practice in this field. I hope that scientific readers who find it hard to cope with his style of argument, and in particular with his Christian presuppositions, will nevertheless persevere with the book if only for the sake of the fresh perspective it opens up.

One of the discouraging and perplexing features of many of the moral choices facing medical practitioners is not the fact that difficult decisions have to be made, but the sense that medical practice is part of a vast and seemingly inevitable process of social change. It is the pre-emption of choice which is worrying, and this is why no amount of analysis of particular cases, and no attempts to specify legal limits in relation to this or that technique, can fully resolve the underlying dilemmas. Effective moral comment entails criticism of the cultural assumptions which make it easy and natural to look for one kind of solution to our practical problems in preference to another. Only by tackling the issues at this level is it possible to see, and maybe begin to counteract, the full implications of runaway technology.

The impact of living in a technological culture carries particular threats for the process of human begetting. What distinguishes our relationship with human beings in such an environment is precisely the fact that they are not "made".

> A being who is the 'maker' of any other being is alienated from that which he has made, transcending it by his will and acting as the law of its being. To speak of 'begetting' is to speak of quite another possibility than this: the possibility that one may form another being who will share one's own nature, and with whom one will enjoy a fellowship based on radical equality [p.2].

It is this radical equality, this deep set of assumptions about the status and being of persons, which Professor O'Donovan believes is eroded by reproductive techniques which break up the act of begetting into a series of manipulations. If it is objected that science and medicine are doing no more than to supplement natural processes which have gone wrong, then the reply is that it is precisely this assumption — that every human ill has a technological answer — which in the end threatens our humanity.

The theme is illustrated by reference to trans-sexual surgery, artificial insemination by donor, experimentation on embryos and *in vitro* fertilization. The first of these raises important questions about the degree to which social perceptions of a person's sex can be used to justify surgical interference with the given characteristics of their body. The second highlights the erosion and confusion of the role of parents. The third leads to an illuminating discussion of the meaning of the word "person", and the tendency to convert a concept whose primary reference is ontological and historical into a qualitative term, indicating the possession of a particular quality, "personality". Embryos, on this latter view, do not yet possess personality and so may be experimented on as being interestingly human but not yet persons to be respected. O'Donovan comments,

> The practice of producing embryos by IVF with the intention of exploiting their special status for use in research is the clearest possible demonstration of the principle that when we start making human beings we necessarily stop loving them; that that which is made rather than begotten becomes something that we have at our disposal...[p.65].

On IVF itself he accepts the arguments for "assisted reproduction", but wonders whether the price in terms of research and risk-taking is morally too high.

This is not a book which will please those who follow their scientific and technological noses wherever the evidence and opportunities lead them. Even a sympathetic reader like myself spattered the margins with question-marks. Its merit is that it raises some fundamental issues about the character of the civilization we are making (the word is significant) for ourselves, in a way which gives current dicussions of particular techniques a new sense of urgency. The fact that its title echoes a phrase in one of the Christian creeds, referring to Christ as "begotten not made", is a reminder of the extent to which traditional Western assumptions about the nature and value of human life have been rooted in Christian theology. I suspect that theology still provides the best defence against the dehumanizing tendencies of a technological culture, but it has to be admitted that, humanly speaking, the defence looks uncomfortably fragile.

John Habgood is Archbishop of York.

The orderly chromosome

J.R.S. Fincham

Molecular Evolution and Organization of the Chromosome.
By A. Lima-de-Faria.
Elsevier Science: 1984. Pp.1, 186. Dfl. 450, $191.50.

THE scope of this book is broader than its title might suggest; it provides a reappraisal of genetics and a very individual view of life. Its main weight lies in an extensive review of many aspects of chromosome behaviour, especially those involving interactions between different parts of genomes. The author has for many years promoted the idea of the "chromosome field", the essence of which is that the arrangement of sequences within chromosomes matters for function. There is therefore much emphasis on such topics as *Drosophila* variegation-type position effects, control of the activity of nucleolus-organizer regions, the activity of centromeres and neocentromeres, and inter-chromosomal effects on crossover frequency. None of these has yet been explained in molecular terms, but the author is quite clear that they are molecular phenomena.

In his preface, Professor Lima-de-Faria remarks that his book is mainly based on the 25,000 reprints in his personal collection, supplemented by over 3,000 photocopies. Many of these have been drawn upon to supply the book's copious tables and figures which, for the most part, appear with legends reproduced verbatim from the originals. This does not always conduce to close integration with the text but at least helps, I suppose, to minimize error. In preparing a book of the magnitude, it is obviously difficult to be up-to-the-minute in every area; of the (approximately) 2,000 references in fact fewer than 10 per cent date from within the past five years. Thus we find only a brief mention of the nucleosome and little or nothing on non-histone proteins, the sequences of eukaryotic promoters and enhancers, methylation and the relationships of all these to states of transcriptional activity and inactivity.

It is clear that Lima-de-Faria's object in writing this book was not only to review a field but also to correct a number of what he sees as misconceived notions in modern biology. In nuclear cytology he considers that much harm has been done by the concept of chromosome *mechanics*. He looks to molecular rather than mechanical explanations of chromosome behaviour, and evidently sees a conflict between the two. More generally, he is in profound opposition to the idea of randomness, and upholds the principle of order in all things.

This attitude emerges in a number of striking passages. Discussing meiosis (p. 923), he dismisses the view that disjunction of different bivalents occurs at random, making the point that, if this were so, there would be nothing to prevent whole parental chromosome sets from segregating out together. Rather, he says, the bivalents are *directed* to segregate independently of one another. Earlier in the book (p. 415) he criticizes Ohno for his speculation that many segmental rearrangements have been fixed in evolution by chance, being in themselves neutral or "harmless". Lima-de-Faria maintains that to say that a rearrangement is harmless is to imply that there is an organization in the chromosome that could in principle be harmed and so Ohno is contradicting himself — a formidable logical trap indeed! Naturally, Lima-de-Faria has no time for the concept of "junk" DNA, disposing of it with another brief argument (p. 1,030). When one actually looks at such a piece of putative junk, he says, one finds that it has a definite sequence and definite locations in the genome — it clearly is not accidental at all! It is not surprising to find him also opposed to the idea of mutations occurring at random; he points out that they are now known to have causes, including that new class of directive agents the transposable elements. Indeed, nothing is accidental in Lima-de-Faria's view of the world. Everything is determined by the laws of physics and chemistry.

As a corollary of his belief of physico-chemical determinism, Lima-de-Faria considers that natural selection is a greatly over-rated concept. "Selection", he says (p. 147), "appears to be impotent in producing major changes in the face of the molecular determination locked in the chromosome and the cell". As a means of explaining evolution, natural selection is largely redundant in any case, since there is not that much evolution to explain. Organisms use their genes in so many ways that they do not need to have many of them, and most of those that they do have they have in common. Thus (pp. 1,060) the bee orchid is able to imitate the bee, and a grasshopper is able to camouflage itself as a leaf, because insects and plants share many of their genes!

Those who have access to this book will find it useful in at least two ways. First as an extensive and generally interesting collection of snippets from Professor Lima-de-Faria's reprint library, second as a rich source of quotations suitable for use as provocative essay topics for first-year students. ☐

China under the plough

Charles Higham

Science and Civilisation in China. Volume 6, Part II Agriculture.
By Francesca Bray.
Cambridge University Press: 1984. Pp. 724, £50, $99.50.

THE vastness and longevity of Chinese civilization are the joint themes of one of the great scholarly adventures of the century: Joseph Needham's *Science and Civilisation in China*. Even the most casual acquaintance with the successive volumes will rapidly dispel any ethnocentric smugness on the part of the Westerner in the priority or superiority of his Graeco-Roman heritage. For the sinophile, each new volume is, by definition, the basic reference in English. The latest to appear is arresting not only because it is the first to be written by one of Needham's research associates, but also because its theme, agriculture, is basic to any appreciation of the productive forces which underwrote Chinese civilization.

Let it be said that this is a massive compilation: the references alone run to 50 crowded pages, and 38 are necessary to contain the index. The preceding text follows an almost military step. The first section stresses China's geographic and climatic diversity, setting the stage for the subsequent contrast between the dryland systems of the north and the wet rice cultivation which characterized the warmer terrain south of the Yangtze. We are then introduced to the source materials, their potential and deficiencies. Literary sources begin with the Shang oracle texts and proceed through three-and-a-half millennia of expansion, addition and recension. The growing body of archaeological evidence illuminates the earlier half of the history of Chinese agriculture, and supplements the historic sources for the later phases.

The main empirical thrust is reserved for a detailed and analytical review of cultivation systems, land tenure, classes of tools, crops and techniques of soil preparation, husbandry and, of course, harvesting, processing and storage. Apparent blind spots, such as the methods of water control, have been considered in earlier volumes or are promised for later ones.

It could be argued that the vast array of facts would have revealed more structure had the author treated her subject holistically, reviewing, for example, first the prehistoric and then the dynastic phases sequentially rather than taking specific implements or techniques and following their development through the millennia. The non-specialist must be nimble-minded to be aware, all the time, where he is chronologically. This possible source of confusion is not mitigated by the illustrative material. It is true that many of the original Chinese drawings of agricultural scenes are charming and highly informative. They would have been more so had the author placed a date or at least a dynasty in the caption. Many of the author's illustrations are most uneven in quality; many also lack a scale, and those scales which are provided vary between the imperial and the metric.

Yet it must be remembered that this is but one of a series of volumes which aims to detail Chinese achievements in all fields, blow by blow. It is not, by definition, an entity with the aim of synthesizing Chinese agriculture within its social and technological contexts. It is, therefore, refreshing to find that we are not denied some contextual analyses.

Agriculture is the engine which sustains statehood. The polity out of step with its agricultural system will soon trip. Through the millennia of population growth, territorial expansion and external threat, the Chinese farmer has displayed a necessary blend of innovation and conservatism. We are invited to consider three instances of the articulation between society and subsistence.

The first concerns agriculture under the Shang. Shang civilization is regarded as the earliest complex society in China, flourishing for five centuries from *c.* 1500 BC. The basic issue is how the Shang rulers, bureaucrats and craft specialists were sustained in such centres as An-Yang. The agricultural techniques of the Shang peasantry are hardly known: archaeologists have concentrated on royal tombs and élite residences, and oracle bones are not concerned with the minutiae of agriculture. Bray favours a system based on plough cultivation. Now the plough is a very important implement. Goody, whose basic text on the social implications of ploughing is absent from the bibliography, has stressed the adhesions which exist between the extra productive capacity of ploughing and social organization, generation of surplus and the organization of marriage and inheritance. Archaeological sources are silent on the issue of Shang ploughing, however, and it could be argued that Bray has tried unduly hard to extract the necessary evidence. For example she is in error when describing the bronze ploughshares from Tonkin as being contemporary with Shang. Vietnamese archaeologists are unanimous in ascribing them to the Dong Son culture, which is a millennium later. Again, Wheatley's view is that the Shang centres were more ceremonial and élitist than centres of dense population. If he is right, then the need to invoke ploughing to produce large food surpluses is reduced.

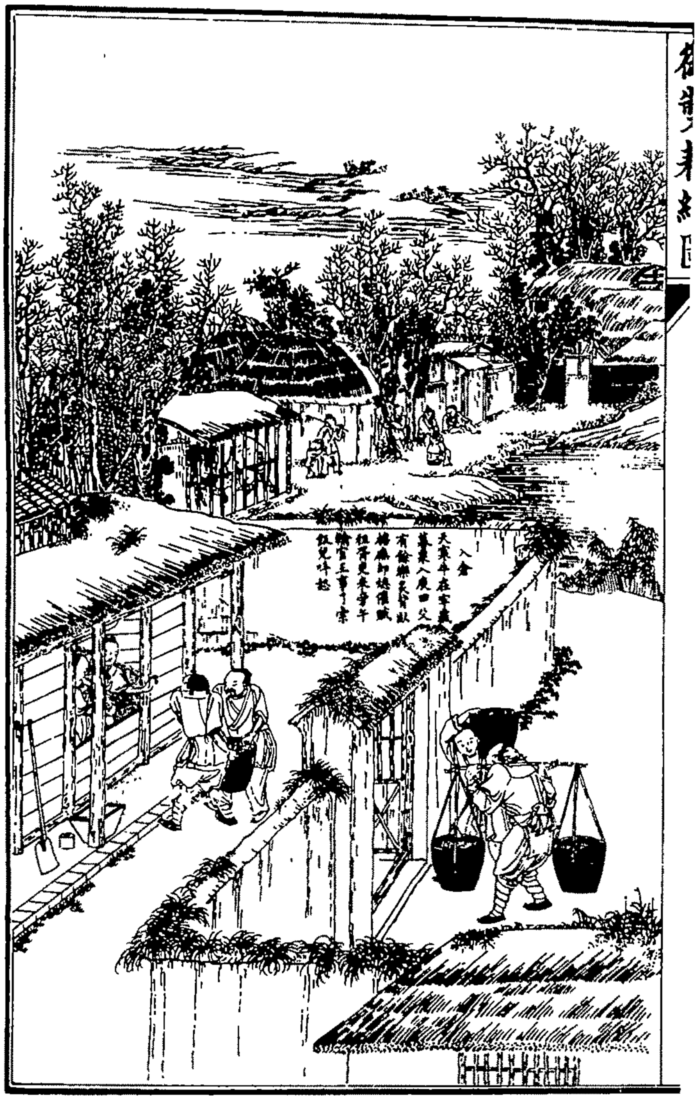
The author is more assured when handling documentary sources. As a second example, we are given a revealing glimpse of the changing basis of land tenure under the Han — the state-sponsored aid to improve output provides so many parallels with recent Western attempts that one needs reminding that Han events took place 2,000 years since.

During the Sung the political centre of China moved south to the wet rice lands, and this introduces Bray's third instance of the articulation between social and agricultural variables. The wet rice agricultural technique involves parcelling the land into level plots separated by bunds. The soil in these fields — which are always small and often minute — is turned by the plough, then converted by harrowing to a creamy consistency prior to the transplanting of rice from a seed bed. The labour input during the planting and harvesting seasons is very high, and the regulation of water flow during the growing season is crucial. During the off-season, however, peasants may turn to cottage industry or, given the surpluses produced by farmers, some may specialize in craft production or exchange.

A basic tenet of this work is that such an essentially small-scale individual or family system is not susceptible to the revolutionary changes in productivity and intensification which characterized Europe's industrial revolution. So we encounter an intriguing paradox: growing European familiarity with Chinese agricultural technology, particularly the efficient curved metal mouldboard and the multiple seed drill, had a revolutionary impact when applied to European agriculture. In China, however, intensification in the face of a rising population involved not mechanization, but subtle refinements in wet rice agriculture which, of its very nature, failed to enter into a multiplier effect with the social or technological systems. This interplay did not stop with Mao's revolution: in effect modern production teams are a close image of the Sung communal unit, the backbone of wet rice cultivation.

The debate which such hypotheses will surely stimulate requires the full availability of data, an axiom which has been scrupulously adhered to. The portrayal of Chinese agriculture requires the broad brush of generality and the miniaturist's stroke of critical detail. This monumental and important book has both in full measure. ☐

Charles Higham is Professor of Anthropology at the University of Otago, New Zealand.



The illustration is taken from *Science and Civilisation in China* depicting a thatched village granary.

Out of the blue

Derek W.G. Sears

Chondrules and Their Origins.
Edited by Elbert A. King.
Lunar and Planetary Institute, Houston: 1984. Pp.377. $33.

CHONDRULES are millimetre-sized silicate assemblages found in meteorites and, like their hosts, they have a unique story to tell about the conditions in the early Solar System. Hitherto, information about them has been spread through a vast literature. So an entire book devoted to the topic is long overdue.

Chondrules and their Origins is essentially the proceedings of a two-day workshop held at the Lunar and Planetary Institute, Houston, in November 1982. It suffers all the strengths and weaknesses typical of such books. The contributed papers are highly variable in approach and quality — some are significant new contributions, a few are useful reviews, and some are brief re-statements of particular views — and the coverage of the subject is rather patchy. Several prominent contributors to the field are conspicuous by their absence and, while petrologic studies abound, chemical and isotopic papers are under-represented; of the 25 papers included, 14 deal with petrology, 3 with chemistry and 3 with isotopic studies (of which only one is on radiometry). There are also 5 which deal with model-making, qualitative and quantitative.

Examples of the useful reviews are the summary of radiometric work by Swindle, Caffee and Hohenberg, who conclude that the chrondrule-forming epoch was brief and occurred at the time of the formation of the meteorites (and the Solar System), and the masterly synthesis of compositional data by Grossman and Wasson. The latter authors argue for a view that has become popular within the past few years, namely that chondrules were formed by the melting of pre-existing, fine-grained dust. The once-popular idea that chondrules could form directly by condensation from the nebular gas has almost no supporters now, although Blander advocates a modification of the idea. In a somewhat more narrowly-focused, but equally worthwhile review, Taylor, Scott and Keil amass arguments against the idea that chondrules could form by impact, volcanism or accretional heating.

One notable example of an original contribution is the paper by Nagahara, who describes another major line of evidence that chondrules were made by melting pre-existing dust; she describes several grains which survived melting. Another is the article by R.N. Clayton and co-workers; on the basis of oxygen isotope data, they argue that although the chondrules from different classes of meteorite formed from different solid material, they were melted in a common gas. There are also two brief but fascinating accounts of astronomical data relevant to chondrule formation by D.D. Clayton and D. Heymann.

In his foreword, Elbert King, the editor, states that his aim was to provide a broad overview of current ideas. I am not convinced that the book succeeds totally, being top-heavy in specialized contributions and leaving certain areas devoid of attention. For example, a review of ideas on the heat-source which melted the chondrules would have been welcome. The book might also have come closer to achieving its aims had it been organized differently — the sequence of papers, alphabetical by first author, is probably the least helpful possible. Surely it would have been better to have gathered the papers by subject area, with each section being led by a review. Still, the book has served as a vehicle for many valuable papers which might not otherwise have been written, and for that Elbert King is to be congratulated.

Derek W.G. Sears is a Professor of Chemistry at the University of Arkansas, Fayetteville.

Amphibian's book of lists

Jonathan Slack

Amphibian Morphogenesis.
By Harold Fox
Humana: 1984. Pp.301. $59.50 (US), $69.50 (elsewhere).

TABLES of standard stages enable embryologists to know precisely at which point in development their experiments have been conducted and to communicate this information to others. But anyone who has worked with amphibian embryos probably feels that stage series are somewhat arbitrary and do not capture the true intrinsic periodization of development. Embryos seem to spend hours at stage 9 (late blastula) and then gallop through gastrulation to stage 13. There they wait for even longer and then race even faster through neurulation to stage 20. Presumably the springs which drive the morphogenetic movements are being coiled at stage 9 and stage 13 and the subsequent events represent the mechanical consequences.

Amphibian Morphogenesis must be the first book to list stage series for 192 species of amphibia, a more or less comprehensive collection. Alas it is just a list. None of the potentially interesting features of stage series are critically discussed, for example the question of intrinsic periodization or the extent to which the timing of one event can be altered relative to another in evolution. The list-like quality pervades the whole book and makes one aware of the difference in approach to a problem adopted by biomedical scientists on the one hand, who are chiefly interested in developmental mechanisms and regard amphibia as useful models for experimental work, and zoologists on the other who would like to catalogue the anatomy, physiology, ecology and evolutionary history of all 2,850 amphibian species.

This book will probably fail to satisfy either audience. Its core is Section III which reviews organ development in larvae. This is the best part and although it is dull reading it will be useful in laboratories such as mine where occasionally we suddenly want to know all about the development of the lateral line, the cement gland or the blood. It contains a useful collection of references but would have benefited from more diagrams and more light microscope photographs. It is full of electron micrographs but these are relatively uninformative because the magnification is too great to show the specific features of the tissues.

There are three other sections in the book, dealing with evolution (I), stage series (II) and embryogenesis (IV). Curiously enough, on close inspection, all of them seem to be mainly about hormones and metamorphosis just like Section III. The full and meticulous references to metamorphosis contrast strangely with the casual treatment of other subjects; for example on p. 4 we read that

> During the warm, moist period of the Carboniferous era, the earth was covered by swampy forests and giant ferns, which later fossilized into coal. Conditions were favorable for amphibian development and a great variety of them evolved in this great age of the "Amphibia," for they required warmth to maintain a high enough body temperature, the prevailing moist atmosphere hindered desiccation and food was plentiful.

We must conclude that this is essentially a review article about metamorphosis onto which has been grafted some rather subjective passages about other aspects of amphibian biology. Only those with a passionate interest in metamorphosis are likely to be tempted to acquire it. □

Jonathan Slack is the Head of the Experimental Morphology Laboratory at the Imperial Cancer Research Fund Laboratory, Mill Hill, London.

New at the Boston show

The products covered this week include some on view at Nature's *Boston conference, and some recent introductions in the field of biotechnology.*

- A new C-tailing and cloning system intended to bring convenience and reproducibility to the construction of DNA recombinants, capable of transforming *Escherichia coli* cells at high levels of efficiency, has been introduced by New England Nuclear (NEN). NEN's new C-tailing and cloning system is self-contained and provides an oligo (dG)-tailed cloning vector, all critical chemical reagents, ready to use competent cells, control DNAs and procedures for successful, reproducible incorporation of DNA into the *E.coli*-pBR322 host-vector system. The method can be used to clone any double-stranded DNA, but is especially useful in cloning cDNA and DNA not suited to cloning by other methods. The results provided with the kit confirm that a control *Hae*III digest of M13mp8 DNA receives uniform, compact C-tail distribution in the biologically active range (15–25 residues). And, following annealing of the C-tailed digest to the system's oligo (dG) tailed pBR322 vector, transformation levels in competent cells are between 2×10^5 and 1×10^6 transformants per μg vector.

Circle No. 100 on Reader Service Card.

- For convenience in precasting 14×16 cm gels for use in Hoefer vertical slab gel units SE400, SE600, and SE700, Hoefer Scientific Instruments now offers a multiple casting chamber, the SE615. Up to ten 1.5-mm thick gels, or eleven 0.75-mm gels may be cast simultaneously. This greatly reduces gel preparation time and ensures unformity in pore size and/or gradient shape from one gel to another. Gradient gels are poured from the bottom of the chamber. Precast gels can be stored for two weeks at a time. The unit is made of sturdy acrylic plastic, and the front panel is removable to facilitate assembly and disassembly of the stack of glass plate sandwiches.

Circle No. 101 on Reader Service Card.

- Triton Biosciences Inc. now manufacture affinity purified antibodies to an oncogene protein and a transforming growth factor. Each antibody is generated against a synthetic peptide corresponding to an amino acid sequence in the native protein. The antibodies are purified by affinity chromatography, and Western blot and immunoprecipitation analyses are used to verify reactivity and specificity. Anti-ras$^{\text{Ha}}$p21 antibody is the first in a new series of oncogene analysis products from Triton. Ultimately such antibodies could be used in diagnostic tests to detect human malignancies.

Circle No. 102 on Reader Service Card.

- New England Biolabs has developed an *in vitro* method for creating novel DNA cleavage specificities by using DNA methylases in conjunction with restriction endonucleases as a valuable new tool for gene cloning and DNA sequence analysis. Added to the New England list of 78 restriction endonucleases are: *Dpn*I (GmA/TC), *Xho*II (Pu/GATCPy), *Sna*BI (TAC/GTA), *Hin*PI (G/CGC), *Nla*III (CATG/), *Nla*IV (GGN/NCC), *Ssp*I (AAT/ATT), *Spe*I (A/CTAGT), *Nhe*I (G/CTAGC), *Nsi*I (ATGCA/T) (isoschizomer of *Ava*III), and *Dra*I (TTT/AAA) (isoschizomer of *Aha*III). New DNA methylases include: M.*Alu*I, M.*Cla*I, M.*Taq*I, M.*Hph*I and *Dam*. New M13 cloning vectors now available are: M13mp10w RF I DNA, M13mp11w RF I DNA, M13mp18w RF I DNA and M13mp19w RF I DNA. Among the new products from the range of New England Biolabs' Organic Synthesis Division are the following phosphorylated linkers: p*Xba*I, d(pCTCTAGAG) and p*Bcl*I, d(pCTGATCAG).

Circle No. 103 on Reader Service Card.

- A new product data sheet from Schleicher & Schuell gives specifications and selection guidelines for S&S pure NC nitrocellulose, the standard immobilization matrix in nucleic acid and protein research. S&S nitrocellulose is highly selective and offers high binding capacity, low background radiation, and lot-to-lot consistency. S&S NC is suitable for the transfer of RNA, DNA, and protein, capillary and electrophoretic transfers as well as plaque and colony hybridization studies. It can also be used in trichloroacetic acid precipitations and dissolved for scintillation counting. The illustrated fact sheet includes a selection guide for choosing the most suitable dimension, pore size, and format. S&S pure nitrocellulose is available in a wide variety of sizes of circles, squares, sheets, and rolls, with special grid patterns, and in pore sizes ranging from 0.45 μm to 0.025 μm.

Circle No. 104 on Reader Service Card.

- Monoclonal anti-human kappa (Clone TB28), a new antibody from Becton Dickinson, is specific for the kappa light chains of all classes of human immunoglobulins and Bence–Jones kappa does not react with lambda light chains, giving superior results in tissue staining of frozen sections. Anti-kappa reacts with 50 to 70% of normal B lymphocytes and with Ig2 leukaemic cells, and can be used to study the clonality of B cells in tissues by indirect immunoperoxidase techniques.

The Systec DNA synthesizer (top) and Pharmacia's electrophoresis system.

- The Systec Microsyn-1460 dual-cell DNA synthesizer permits the continuous synthesis of DNA oligomers with a coupling efficiency of 99%, or more, per step and a cycle time of 6 min using the phosphoramidite method. Two synthesis cells allow the continuous sequential synthesis of multiple oligomers, maximizing DNA production while minimizing operation time and cost. The Microsyn uses flexible RAM-based control software making possible the automation of all phosphate and phosphite methods, as well as user modification of Systec's standard methods. Sequence programming is simplified by an "ACGT" keyset, allowing the rapid entry of single and mixed probe base additions. Valves have been tested to 1 million cycles, the equivalent of 10 years of use, and all parts and labour are fully warranted for one year.

- New from Pharmacia Fine Chemicals are two new injection-molded nucleic acid electrophoresis systems of the classic "submarine" design. The "mini", GNA-100 apparatus gives rapid separations (0.5–2 h) and allows detection of very small amounts of material. The larger, full-size submarine format, GNA-200, allows many samples to be run on one gel (up to 60) with maximal resolution. Other features include UV, transparent lids and gel trays, rugged titanium-based electrodes, and buffer circulation ports with interconnecting stop-cock. Especially suited for analysis of restriction enzyme digests, the new GNA-100 and GNA-200 are complete and ready-to-use.

Circle No. 107 on Reader Service Card.

- First introduced at the European Congress on Biotechnology in Munich last month, the ISF fermenter from Infors AG is available in three sizes of 1 - 70 litres working volume. It is compact and features either a top or bottom drive. Drive characteristics can be selected without special tools. The bottom valve with high current flow is combined with the sampling port which allows extraction of very small probes. Sterilization *in situ* is guaranteed. Sterilization of the air inlet and outlet systems can be effected independently of the vessel. Specially designed systems are built into the fermenters to avoid by-pass lines and during sterilization the air inlet and outlet lines are automatically separated from the vessel. A programmable sterilization sequence controller reduces waiting time.

AUTHORS WANTED BY N.Y. PUBLISHER

A well-known New York subsidy book publisher is searching for manuscripts worthy of publication. Fiction, non-fiction, poetry, juveniles, travel, scientific, specialized and even controversial subjects will be considered. If you have a book-length manuscript ready for publication (or are still working on it), and would like more information and a free booklet, please write:

Vantage Press, Dept. D-69
516 W. 34th St., New York, N.Y. 10001

- An immunofixation electrophoresis (IFE) assay kit is now available in the Paragon electrophoresis product line from Beckman Instruments. The new Paragon IFE test provides a fast, sensitive and easy-to-read method for diagnostic identification of monoclonal gammapathies, immunoglobulin deficiencies and other immunoglobulin anomalies; IFE is a procedure combining protein electrophoresis and immunoprecipitation.

Circle No. 109 on Reader Service Card.

- Using Bio-Rad's mini vertical slab cell it is possible to analyse protein and nucleic acid samples two or three times faster than with conventional 16 cm cells, while maintaining comparable resolution. The cell controls heat related artefacts, and a variety of spacers and combs allows one to produce exactly the gel configuration needed for each specific application.

- The New Brunswick Scientific GEN II microprocessor-controlled instrumentation system provides fully distributed P I D or on/off control of fermentation processes. Up to 11 modules, each dedicated to the control of a specific fermentation parameter, can communicate with each other to provide dynamic control of the process as metabolic conditions change. The GEN II system is entirely self-contained, but can be operated by a supervisory computer or through remote terminal communications.

- The RF-1 incubation system from Bioengineering Associates Inc. is a virtually noiseless incubator shaker of a compact, space-saving design. The magnetic drive assures maintenance-free operation. A digital panel display indicates actual and set-point speed which is continuously adjustable from 40 to 400 r.p.m. (± 1%). The incubator is fitted with a Pt 100 sensor for precise temperature control (± 0.1°C). Should temperature deviate 0.8°C from set point, the digital display starts flashing and an accoustical alarm sounds every two minutes until the condition is corrected. A humidification system, operating on the evaporation principle, is built in. All materials are selected for resistance to corrosion and will withstand continuous operation.

Circle No. 112 on Reader Service Card.

- The mixed sequence hexadeoxynucleotides used by Feinberg and Vogelstein in the development of their new method of generating radio-labelled DNA probes are now available from Pharmacia P-L Biochemicals. Also available are di-, tri-, tetra- and pentadeoxynucleotides. The random sequence hexadeoxynucleotides hybridize to any isolated restriction fragment. The hexadeoxynucleotides then act as primers for DNA synthesis using the DNA polymerase 1 Klenow fragment in the presence of radioactive deoxynucleotide triphosphates, thus generating radiolabelled copies of the fragment.

The RF-1 incubation system from Bioengineering Associates (top) and New Brunswick's fermentation controller.

- Two full-range, hand-held *p*H meters with clear digital displays have recently been introduced by Corning. Constructed to cope with indoor and outdoor working environments, the new meters — Models 103 and 105 — can be used with either remote or clip-on electrodes and offer a resolution of 0.01 *p*H units. The meters can also be used for ion selective electrode work.

Circle No. 114 on Reader Service Card.

- The LKB Transphor 2005 electroblotting unit uses the principles of electrophoresis to transfer proteins or nucleic acids from polyacrylamide or agarose gels onto nitrocellulose, DBM, or other immobilizing matrices. By binding molecules in concentrated bands on one of these matrices, electrophoretic bands are made easily accessible for faster, more sensitive and more quantitative visualization than possible on the original gel or even on a non-electrophoretic blot. Detection procedures are also more economical as they require smaller amounts of reagents.

Circle No. 115 on Reader Service Card.

- An applications laboratory is now available at Microfluidics Corporation, Newton, Massachusetts, for processing customer samples and for demonstrations in the fields of fine emulsions, liposomes and dispersions. Prototype formulation work is also underway, utilizing the company's latest Microfluidizer equipment. Samples as small as 15 ml can be processed and flow rates up to 350 ml min^{-1} are available. Particle size and distribution analysis of processed samples is provided.

New joint ventures in Europe

Next week's meeting of European science ministers at Paris is unlikely to accomplish much, but at least it makes a start on the improvement of science collaboration. Where next?

THE Council of Europe can hardly be accused of being bossy. Its faults are rather those of ineffectiveness. The council (which, with twenty-one members, covers a wider swathe in Europe than, say, the European Communities) is best known as the source of international conventions which have the force of law in Europe when ratified by member governments. (The human rights convention works well, the convention on laboratory animals has been five years in negotiation and is still not complete.) The council also stages large inter-governmental conferences of monumental banality such as that labelled "Education 2000" at Strasbourg (the council's home base) last November and that on communications and society. So how does such an organization come to be staging an important meeting of European ministers responsible for research at Paris this weekend? And can it be trusted with the responsibility?

The oddest feature of the meeting is not the agenda, which is excessively modest, but that there is one of any kind. The origin of next week's meeting goes back to the stirring speech to the council's parliamentary assembly by M. François Mitterrand, the President of France, on what has become the characteristic French theme in Europe (and in France) — that Europe's economic future rests on the better use of science and technology. What Charlemagne once did by conquest, to create economic and political power out of unity, M. Mitterrand would accomplish by the coordination of European research and development. M. Mitterrand can congratulate himself that he has been listened to so well. And if the agenda for next weekend is only modest, there is always a chance that it will lead to better things.

Objectives

The omens are encouraging. Even governments such as the British, whose hostility to much of the council's work stems not so much from insularity as from the wish not to be distracted from preoccupations of its own choosing, seems willing to go along with what is proposed. Two objectives dominate the agenda — the improvement of the networks linking research people in Europe, and providing encouragement to the mobility of scientists. If all turns out as planned, the chief beneficiary of the conference next week will be the European Science Foundation (also Strasbourg-based), which will be urged to encourage the development of research networks on a European basis (but told to raise the money for that from its members, mostly European research councils). This is a timely recognition of the foundation's success, during the past decade, in creating mechanisms of collaboration in fields as different as neurophysiology and the uses of synchrotron radiation (and the development of sources thereof). The other theme, mobility, is necessarily more nebulous. Everybody recognizes that the free movement of research people within Europe would be good for science as well as for the economies of Europe, but there are serious barriers to mobility, deriving from chauvinism and pettifogging administration, to be overcome. The hope seems to be that the Council of Europe and the European Commission can jointly embark on the removal of some of these obstacles once the weekend is over.

That, for those who attend, is the applause. The other side of the coin, of which they should be made aware, is that the agenda on which they will be brooding is about as modest as any that could have been devised. In the spirit of M. Mitterrand's rhetoric, and no doubt against the background of the many high-sounding things that will be said in Paris, the agreements that will be reached are bound to seem like an anticlimax. Charlemagne made the Rhine into the axis of economic power. But the science ministers — on the same metaphor — will be invited next weekend merely to test the salinity of the river at a few selected points. European politics being what they are, there may be no other choice. But the ministers (and M. Mitterrand) should acknowledge how wide a gulf separates their ambitions and what is likely to be achieved.

The problem

The European dilemma is simply stated. Many Europeans think it prudent to opt out of the ambition of making Europe into an integrated economic power, counting institutions such as the European Communities and the Council of Europe as institutions whose value must continually be reassessed. Even the others, those who hold that European integration in some form may be more than a pragmatic benefit, are divided into separate groups — those who hold that the forging of economic strength in Europe must be an evolutionary process, one small thing leading to another hardly any bigger, and those (numerically fewer) who would prefer to take the bull by its constitutional horns (which is what the signatories of the Treaty of Rome thought they were doing thirty years ago). Rhetoric apart, this weekend's meeting is squarely but limply in the evolutionary tradition.

The present difficulty in Europe is that both approaches are likely to be ineffectual. Softly-softly is too slow. But even constitutional change is frustrated by what are known in the European Communities as "non-tariff barriers to trade". People pay lip-service to the notion that it would be good for Europe if the most efficient manufacturers of, say, mousetraps enjoyed the best sales but they are also willing to bend the rules so as to make sure that only nationally manufactured mousetraps really succeed. In this spirit, one of the European Communities' collaborative projects in technology, the Esprit computer development programme will be a simple and a shocking waste of quite a lot of money if its outcome has to contend with the long-standing chauvinism of European governments towards the products of high technology. Even the modest proposals being discussed in Paris at the weekend will be frustrated if approval for the greater mobility of technical people is alloyed with too much concern that public research funds should always be spent by those who have contributed towards them as taxpayers or that public laboratories should employ only local nationals.

President Mitterrand's ambition will never be achieved if Europe insists on putting the cart before the horse in ways like that. The logic is impeccable. Numerically, even the European Communities are large and rich enough to be an economic unit comparable in size with any others in the world, while the populations concerned are amongst the most literate and skilled that are anywhere to be found. Moreover, Europe is blessed with modern social and economic institutions — universities, for example, or commercial companies and investment institutions. But as things are, the dream is belied by the reality. European governments are these days being repeatedly reminded of how they are slipping in their performance. The British Government, for example, after four years of energetic sponsorship of what it calls information technology, should have been shattered two weeks ago to have been told by a committee of the National Economic Development Office under Professor John Ashworth that this same period has seen a steady deterioration in the balance of external trade in equipment such as computing machinery. The difficulty is that a home-grown industry only poorly supported by research and development, and facilities for education and training, is being exhorted to compete across the board with stronger organizations overseas.

What next weekend's meeting should also recognize is that there is a sharp difference of timing between the urgency of these problems of industrial competitiveness and the time-scale implied by its own agenda. Stronger networks in research are, to be sure, desirable, but will they help with the problems of industrial survival cropping up all over Europe? The simple answer is that they will not. The Council of Europe is, in any case, out of its depth in fields such as this. But the recognition that opportunities are being lost with every year should at least give those assembling in Paris a sense that if their weekend is to be usefully spent they had better look further ahead.

What might the council achieve? New actors can always hope to breathe new life into old parts especially because, since the council's constituency extends between the European Communities, evolutionary and not constitutional approaches are unavoidable. One worthwhile ambition, however, would be to embark on the encouragement of integration in higher education, both in teaching and academic research. Why not seek to engineer the return to the fourteenth century, when it was commonplace that both the students and teachers of European universities were recruited from the whole continent? Why not even go one step further and acknowledge that if the objective is true European scholarship, it will at some stage be necessary that public spending on the support of scholarship, even by national governments, should be channelled always to teachers and people most likely to make use of it? It is unreasonable to expect all scholastic steps in this direction to be taken quickly, but it is illogical not to prepare for it while otherwise behaving as if President Mitterrand's speeches should be taken seriously. □

Election irrelevant

Something must be done about the federal deficit, whatever the outcome of the US election.

WILL interest rates go up or down after the November presidential election in the United States? And will the dollar, now (with the yen) the strongest of international currencies, then lose some of its recent shine? Voters in the United States should know that these questions (together with the administration's policy on arms control) are elsewhere more absorbing and more important than the intricacies of the candidates' relationships with the Inland Revenue Service. Future prosperity in the rest of the world, industrialized and poverty-stricken alike, will be determined by the economic fall-out of the election. The crucial question is how the paradox of US economic policy is eventually to be unscrambled.

The essence of the paradox is now boringly familiar. The federal government has failed to balance its budget to the tune of $200,000 million a year, and seems likely to continue in that way. Only last weekend, President Reagan told an election audience that he had no special plans to act on the deficit after the election, saying that continued growth might automatically redress the balance by increasing tax revenues. The result is that the US Treasury has had to borrow from the money markets to finance its research, to pay salaries to those who work in government laboratories, for example. High interest rates are not, however, necessarily a precondition for successful borrowing, but they are the only way of financing a huge deficit while keeping inflation in check. Everybody agrees about that.

It is also agreed that US policy has been successful within its lights. Inflation has indeed been kept at bay, which is why not only US citizens but people and institutions from overseas are eager to lend to the US Government. So money has been rushing into the United States. The penalty, a consequence of short-term confidence in the dollar, is that goods and services in the United States have become relatively less competitive, so that the trade balance has deteriorated. This year, the United States will not be paying in the usual way for $85,000 million of the goods and services it will be importing, a deficit comparable in scale with the surpluses earned by the oil exporters in the 1970s. That, the United States demonstrated at the end of the 1960s, when part of the cost of the Vietnam war was paid for with paper money printed on the Eurodollar market, which turned out to be a way of exporting inflation. Since then, however, other governments have learned a thing or two, but their only defence against the resurgence of inflation is to keep their own interest rates at a level determined by those in the United States. The paradox is that those who lend money internationally do not usually do so with confidence when a creditor country is in the red both on its fiscal accounts and its balance of trade. Circumstances such as these have dictated retrenchment in an emergency.

Instability

Even in the United States, the strongest economy in the world, this state of affairs cannot last indefinitely. Two British economists, Professor M.J. Artis (University of Manchester) and Mr M.V. Posner (until last year the chairman of the Social Science Research Council) have given elegant explanations of the reasons in the autumn issue of *The Midland Bank Review*. Writing as members of a group of independent economists called the Clare group (after the Cambridge college of that name), they argue that the crucial question for lenders to the United States is not now whether they have confidence in the management of the US economy but whether they consider that other lenders will retain that sense. And since, on arithmetical grounds, the accumulation of both deficits cannot continue indefinitely, lenders have no choice but to second-guess other lenders. Sooner or later, the argument continues, the lenders will begin to lose their nerve, and then there will be only two choices for the US authorities — to increase interest rates still further in the possibly vain hope of continuing to finance the federal deficit or to let inflation run riot again. Either way, the economic recovery of the past two years would be stopped in its tracks.

This argument is not, of course, unfamiliar. It has been repeated endlessly in the past three years, especially in relation to the debts of the developing countries whose financial problems, serious enough a decade ago in the wake of the oil crises of 1983 and 1979, are aggravated as the rate of interest of foreign loans which cannot be serviced is converted to that prevailing in New York. So much, indeed, has been made of the instability of the present situation, and so little has come of these predictions of disaster, that it is tempting to think the general air of gloom must be mistaken. But that cannot be the case. Simple arithmetic decrees otherwise. The question is not whether both deficits can continue indefinitely, but when one or other or both of them must be eliminated, and how.

Obviously the best solution is that the US Administration should recognize the truth of what economists elsewhere are saying, that this state of affairs cannot persist indefinitely. The alternative to action is to wait for it to be resolved catastrophically. The Reagan Administration, whatever its faults, is fiscally well-managed and thus equipped to know when the time has come to change tack. Indeed, *The Midland Bank Review* (not the Clare group as such) takes the line that the change must come within the next twelve months. On the assumption that the administration (whatever its colour) may then have changed course, it guesses that interest rates in New York (and thus elsewhere) will have fallen by two per cent by the end of 1985 — and that the value of the dollar relative to other currencies will also have fallen by 20 per cent. Mr Walter Mondale, the Democratic candidate, has been promising such a change of tack, but for the time being the incumbent President dissents. What the economists are saying is that neither has a free choice. □

Space shuttle

Pentagon gains ground in battle for alternative

Washington

DESPITE a near-perfect maiden flight by the space shuttle orbiter *Discovery* last week, doubts over the shuttle's commercial prospects seem to be increasing. The shuttle successfully placed all its satellites into orbit, and the crew again demonstrated the possibilities of in-flight maintenance. But the day before *Discovery* touched down in California, an expert panel of the US National Research Council told Congress it was "not clear" that the shuttle would ever be competitive with an expendable launcher for military payloads and agreed with the air force's argument that a new launch vehicle would provide it with greater operational flexibility.

This leaves the National Aeronautical and Space Administration (NASA) with a major problem, because NASA had been counting on the military to pay for more than one third of projected future shuttle flights. If the US Air Force insists on developing its own expendable launcher for some of these flights, NASA may well have to increase its prices to civilian customers.

The National Research Council, the research arm of the National Academy of Sciences, was asked by appropriations committees of both houses of Congress to compare options for expendable launch vehicles capable of lifting large payloads into orbit. Its report echoes previous criticisms of the shuttle — main engine and fuel pump performance are still below specification, turn-around times are still too long and, says the committee, "a sustained engineering programme will be required to realize the full benefit" of the shuttle concept.

The air force has been unhappy with the shuttle for some time. Apart from the question of reliability, the Department of Defense has been concerned about the limited number of launch sites and the security difficulties should it wish to launch a sensitive satellite "without the public exposure that has become the norm in NASA flight operations". The research council panel also points out that in time of crisis the shuttle would have to overfly Soviet territory in order to put a satellite into a polar orbit suitable for reconnaissance: here, an unmanned launcher offers obvious advantages. And commercial companies might be happier if the Department of Defense were less likely to requisition planned shuttle flights, as it has the right to do.

The panel examined three possible expendable launchers being considered by the Department of Defense — the Titan 34D7/Centaur, the Atlas II and the SRB-X, which is derived from the shuttle. All are based on existing technology. Any of these would be capable of meeting immediate requirements but none offers the possibility of expansion to carry loads much heavier than 10,000 pounds to geosynchronous orbit, the panel concludes. The cost of developing one of the alternatives would be around $2,000 million.

The research council panel avoids addressing in detail how the prospect of a new competitor to the shuttle would affect NASA finances. NASA at present charges its customers only "out-of-pocket expenses", although there is pressure for it to move to a full-cost policy. But already the European *Ariane* launcher "appears to be competitive" with the shuttle.

While apparently accepting all the military's arguments for a new expendable launcher, the National Research Council panel stops short of giving the project an unconditional endorsement. The main need, it concludes, is for further study of a new class of heavyweight launch vehicle capable of taking payloads of up to 450,000 pounds into low Earth orbit. Both NASA and the air force are already working on plans for such a system, thought likely to be necessary for President Reagan's "strategic defence initiative", better known as Star Wars. Such a system could be designed using motors developed for the shuttle programme with the aim of reducing costs without loss of reliability.

Tim Beardsley

British aerospace

Per atmosphaera ad astra

A BRITISH space shuttle? Surely a joke? Perhaps, perhaps not. A study by British Aerospace of a new concept for the launch of large payloads (up to 7 tonnes) into low Earth orbit comes as the British Government finds itself under increasing pressure from its high-technology companies and its European Space Agency partners to make a positive commitment to space or pass up for ever the chance to keep a presence on the "high frontier".

The new concept, dubbed HOTOL (Horizontal Take-Off and Land Satellite Launcher), is of a vehicle of aircraft type with the ability to take off horizontally and land on a conventional runway. The vehicle would use a combination of air breathing and rocket propulsion.

An ideal re-usable launch vehicle, says British Aerospace, should have no expendable parts (unlike the US space shuttle), should be capable of repeated operations with a minimum turn-around between missions, accommodate payloads in the 4–7 tonnes range and, if necessary, should be capable of unmanned operation.

At present vertical take-off into Earth orbit is impossible because even the highest-performance chemical fuels give a single-stage rocket insufficient impulse. A two-stage lift is essential, so that expensive equipment is irrevocably lost in re-entry or at sea.

British Aerospace proposes to overcome this apparently insurmountable difficulty by economizing on the supply of liquid oxygen, which may account for 85 per cent of the propellant mass of a booster rocket. If air scooped from the atmosphere were to supplement a rocket's supplies of liquid oxygen during the early phases of flight, its dead weight might be substantially reduced. Add wings for additional lift and there it is — HOTOL. British Aerospace believes the system capable of revolutionalizing the space industry.

It is unlikely that Britain would have the resources to undertake such a major project on its own. If life were to be breathed into the idea, a collaborative effort, perhaps with other European countries, would seem the most prudent course to take.

It is just such a collaboration that European ministers are now pressing Britain to join, chiefly in the form of a European consortium to take part in the US manned space platform. Britain would be expected to contribute an extra £15 million a year compared with its present spending of just £80 million a year (and France's £400 million), principally for membership of the European Space Agency.

"You'd think we'd have our own departure lounge."
SPAIN
BIRCH

British Aerospace is eager for government support for its space effort. But in the realm of fact rather than fancy, the company has announced a contract, from the US corporation Scott Science and Technology Inc., to design a Satellite Transfer Vehicle needed to carry satellites from shuttle orbits to geosynchronous orbit. The vehicle will be propelled by liquid fuels which, as well as being more efficient than solid fuel, will allow a range of burn strategies tailored to individual missions.

Marcus Chown

Acid rain

CEGB takes a pasting from MPs

BRITAIN should cut back drastically in its emissions of sulphur dioxide and other gases contributing to the problem of "acid rain", with most of the burden falling on the Central Electricity Generating Board (CEGB), according to a report published last week by an all-party committee of Members of Parliament. If the MPs recomendations were put into effect, they would force the CEGB to cut sulphur dioxide emissions by 85 per cent. This would cost "many thousands of millions of pounds" and raise electricity bills "up to 10 per cent", according to CEGB. Moreover, there is no guarantee that the measures (flue gas desulphurization, or in the long term fluidized bed combustion) to reduce sulphur emissions would have any commensurate effect on acid rain itself, the board claims.

But the MPs, after many months' taking of evidence from scientists and politicians in Britain, West Germany and Scandinavia, are convinced that scientific understanding is sufficiently advanced to demand action now. By this they mean that while a direct and proportional link between sulphur emissions and environmental damage is not scientifically proven, the case against sulphur dioxide is telling enough and the damage severe enough that action must be taken before all the evidence is in. In this they agree with a recently-published report by a committee of the House of Lords (see *Nature* **310**, 535; 1984), but the bottom line of the Commons report — its demands — is far more punishing. And the MPs lay less stress than the Lords on the question of "linearity" between sulphur emissions and acid rain effects, a key scientific issue which is generally assumed to remain open. Moreover they quote modelling by Swedish professor of meteorology Henning Rodhe which supports linearity. Rodhe's models indicate that a decline in the acidity of Swedish rain since 1975 was attributable to a corresponding decline in European emissions — if depositions were linearly related to emissions.

Impressed by this and other evidence, and "appalled" by lack of action in Britain, the MPs say Britain must (among other measures):

- Join the "30 per cent club" of nations committed to reductions of 30 per cent in total national emissions of sulphur dioxide by 1990, a target to be achieved solely by cutbacks in CEGB emissions.
- Refit CEGB power stations to achieve a national 60 per cent reduction in sulpur dioxide emissions by 1995.

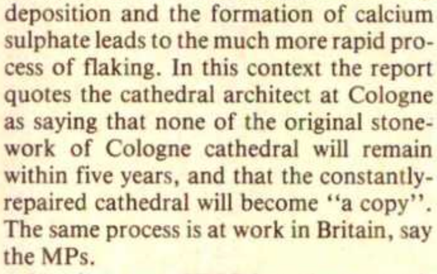
The second measure is broadly in line with an existing draft directive on "large combustion plant" from the Commission of the European Communities (CEC), but whereas CEC says that the measure should be applied to all plant of output greater than 50 MW, the British MPs have singled out electricity supply for attack. "We don't want to affect manufacturing industry", a member of the Commons committee explained last week. As a result, he admitted, the measure would imply that CEGB cut its own emissions by 85 per cent, to achieve the net national reduction of 60 per cent.

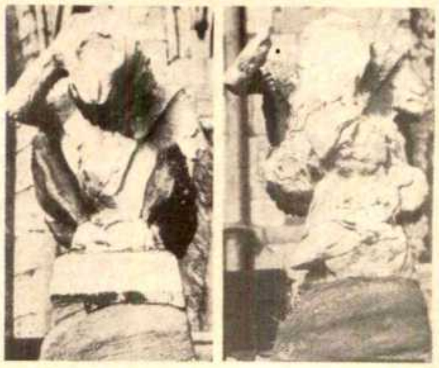
Why should manufacturing industry be feather-bedded? To protect its fledgling rebirth in Britain, the MPs imply, and because CEGB's sulphur dioxide emissions have remained constant since 1970, whereas net British emissions have fallen 37 per cent. This fall was largely due to industry turning away from coal to natural gas (and to the recession).

Overall, it is difficult to avoid the impression that the MPs are singling out CEGB for punishment. Yet the punishment may be deserved. The MPs claim that CEGB "dismissed" the effects of acid emissions on stonework with the remark "to dissolve an inch of limestone would take 5,000–20,000 years", whereas, say the MPs, it is "well-understood" that dry deposition and the formation of calcium sulphate leads to the much more rapid process of flaking. In this context the report quotes the cathedral architect at Cologne as saying that none of the original stonework of Cologne cathedral will remain within five years, and that the constantly-repaired cathedral will become "a copy". The same process is at work in Britain, say the MPs.

In other areas CEGB has "begun work only two years ago" or "made no attempt to monitor effects". And, say the MPs, while CEGB is spending £1.5 million a year on research on the environmental effects of acid rain, it is spending only £200,000 on research on flue gas desulphurization "largely on paper studies of foreign systems".

As for scientific evidence, the committee claims it took pains to get balanced and detailed views in the UK and abroad. "I shouldn't comment on the Lords", said committee chairman Sir Hugh Rossi, "but they didn't do their homework — they didn't go abroad". The Lords' report was consequently superficial, he implied.





Stonework on Lincoln Cathedral, in the plume path of Trentside power stations. "Despite... the knowledge of CEGB research staff that the cathedral was suffering from the effects of sulphur dioxide, CEGB has made no effort to monitor those effects", say British MPs in a new report on acid rain. On the left, a photograph from 1910; on the right, 1984.

The evidence of UK Natural Environment Research Council (NERC) scientists impressed the MPs. These scientists "independent of any manufacturing or industrial interests... told us that scientific work had advanced far enough for a decision to be taken". The minutes of evidence show, indeed, that NERC secretary John Bowman volunteered that although the next five years' research would provide "a good many answers to the questions you have been putting to us... I do not think that should be used as an argument for doing nothing now".

And as for the liming of acidified lakes in Scandinavia — as recommended by the Watt committee on energy (see *Nature* **310**, 535; 1984) — this showed ignorance of Scandinavian research, and mere geography, which made liming impractical even as a short-term measure, committee members said last week. "Anyone who has flown over southern Norway and seen the number of damaged lakes in remote areas where there is no indigenous source of lime would realize this" the report says.

The only solution is for Britain to put its own house in order, say the MPs. But will their advice be taken? The next political step in Britain will be a debate on the report. According to Sir Hugh Rossi the government has promised such a debate before the end of the year. **Robert Walgate**

- Britain's Social Democratic Party (SDP) announced their own solution to the problem last week: energy conservation. "Substantial reductions [in sulphur dioxide emissions] could be achieved rapidly even without the costly installation of desulphurization equipment in power stations if the government invested more in energy efficiency measures. A five per cent cut in electricity gneration would enable Britain to meet the Select Committee's targets by the early 1990s, at half the cost estimated by the CEGB. It would also improve the competitiveness of industry", the SDP claims. □

Laboratory animals

Animal rights lobby cashes in

THERE is still no word from the British Government on the progress of its new animal experimentation legislation. More than a year has passed since the release of the White Paper — "Scientific Procedures on Living Animals" (see *Nature* **303**, 191; 1984) — containing draft proposals for the replacement of the Cruelty to Animals Act of 1876 with more effective and less anachronistic controls. In that year, the views and critical comments of concerned organizations have been collected and assimilated. Moderate animal rights groups are now hoping that a suitable response, in the form of a supplementary White Paper, will be published by the end of the year.

Meanwhile, the more extreme animal rights groups, including the Animal Liberation Front (ALF), have stepped up their campaign against animal experimentation with paramilitary style attacks on selected institutions. Government laboratories have been forcibly entered, equipment damaged and records essential to research stolen. Pharmaceutical companies have also suffered harassment and intimidation of their employees. And Mr David Mellor, Under-Secretary at the Home Office and the man principally responsible for preparing the new legislation, has become the object of escalating harassment which, he says, has included threats on his life. Meanwhile, a coalition of organizations including Animal Aid and the British Union for the Abolition of Vivisection, has drawn up a list of minimum requirements which, it says, must be part of the legislation to replace the archaic 1876 act. It wants to see a complete ban on tests of cosmetics, alcohol and tobacco, behavioural and psychological tests, warfare experiments and, more specifically, two routine tests it considers particularly offensive: the Draize eye test in which irritants are put in the eyes, usually of rabbits, until damage is caused, and the so-called LD50 toxicity test in which animals are given increasing doses of a test substance until half have died.

The coalition is unlikely to be satisfied with the proposed measures which, in order not to hamstring British companies by prohibiting experiments that competing foreign companies would be free to carry out, avoids a complete research ban. The proposals differ from the old act in the following ways:

- The 1876 law, which only governs experiments, will be extended in scope to address procedures such as the production of antisera and the passaging of tumours.
- A statutory Animal Procedures Committee will replace the previous non-statutory body.
- Laboratory animals will have to be obtained from registered establishments, outlawing the use of strays.
- The 1876 law required all animals recovering from anaesthesia to be compulsorily killed but, today, some surgical procedures are relatively mild and anaesthesia is used principally to immobilize a subject. This requirement is to be waived in such circumstances.
- The conditions in which animals are maintained will be regulated.
- Home Office inspectors will need to be satisfied that a procedure is justifiable and that no satisfactory alternative to the use of animals is feasible, that the minimum number of animals is used and that the least possible suffering is caused.

The Royal Society for the Prevention of Cruelty to Animals (RSPCA) is generally critical of these proposals. The White Paper advocates the continuation of the present rule that "if an animal is found to be suffering severe pain which is likely to endure, it shall at once be killed". But, RSPCA points out, since the Home Office itself admits it cannot define the terms "pain", "severe" or "enduring", the inclusion of these words in such a pivotal role undermines the credibility of the proposals. Other organizations are also insistent that the pain question be dealt with. The Fund for the Replacement of Animals in Medical Experiments (FRAME) is commited to reducing animal experiments to a minimum and to finding alternatives to animals. In a study, prepared in conjunction with the British Veterinary Association (BVA) and the Committee for the Reform of Animal Experimentation (CRAE) and supplied to the Home Office, it distinguishes two types of pain: unexpected pain inflicted during an experiment, and pain and suffering which is the inevitable consequence of an experiment. In the former situation, FRAME says, the animal should be killed as required by the 1876 act. In the latter situation, permission should be given only in very special circumstances when the experiment is of great importance to human or animal health.

Both the RSPCA and FRAME are unwilling to be too critical of the Home Office until they see its revised proposals and can assess to what extent their advice has been heeded. The new bill could reach Parliament during next year or in 1986.

Marcus Chown

Britain leads the way

DESPITE the flak aimed at the government by animal rights organizations, Britain is ahead of most other European countries in the area of animal experimentation reform. The 21-nation Council of Europe has been trying, since 1978, to perfect a "Convention for the protection of animals used for experimental purposes" (*Nature* **302**, 284; 1983) and the convention is likely to be less strict than the British law. Nevertheless, a European accord on the political horizon could go some way to allaying the fears of pharmaceutical companies that what they perceive as an over-zealous British initiative.

The ageing British act also has admirers in the United States. In a Commentary appearing in *Nature* later this month, an animal rights campaigner argues that the British approach to animal experimentation is much more humane than the US approach. Two bills aiming to improve matters are at present bogged down in the US Congress, with the powerful industrial lobby content to keep them there. □

Bird books safe

Washington

A UNIQUE collection of environmental and natural history documents, including the only known intact copy of the "elephant folio" edition of John Audubon's *Birds of America*, has been granted a reprieve from the auction block. The National Audubon Society had planned to close the library and sell off part of it to raise funds, but the society has now changed its mind after word of the plan leaked out and provoked a minor squall among members and the American Library Association. Many were upset that the board of directors of the society did not consult its membership before taking the decision at its May meeting, and that the society has in fact still made no official announcement on the subject.

According to the library association, the collection, which is housed in the society's New York offices, contains many works on ornithology, wildlife preservation and conservation which can be found together in no other library. It also includes a number of unduplicated nineteenth century works.

The library dispute appears to be part of larger tensions that have been growing between the society's membership and its staff on the one hand and its leadership on the other. Under the presidency of Russell Peterson, the society has become increasingly involved in what is known in the trade association business as "government affairs", that is, lobbying. Peterson attempted to move the entire office to Washington several years ago, but abandoned the plan. Peterson has also involved the society in such issues as global population and nuclear war. Many staff members are known to be displeased with what they see as a swelling bureaucracy — including some 25 vice-presidents — which has grown at the expense of basic programmes.

Although the library will remain intact for the time being, it has been closed to the public and its full-time librarian assigned to new duties within the society.

Stephen Budiansky

Oceanography

Excitement on the seabed

THE US oceanographic and geological community has been "set alight" by a quarter-million-square-mile survey of the Pacific Ocean floor off the west coast of the United States — a survey, completed three weeks ago with the British side-scanning sonar system GLORIA, of the 200-mile exclusive economic zone (EEZ) declared by President Reagan last year under the international Law of the Sea. The survey, says Dr Jim Gardner of the US Geological Survey (USGS) at Menlo Park, has for the first time provided a "road map" of the whole area stretching from the Mexican border in the south to the Canadian in the north, and outwards into the Pacific from the edge of the narrow continental shelf. This map reveals some 200 previously unknown volcanic sea-mounts, "spectacular canyons" 300–500 km long — apparently carrying meandering rivers of sediment along the ocean floor — and almost every kind of plate tectonic boundary.

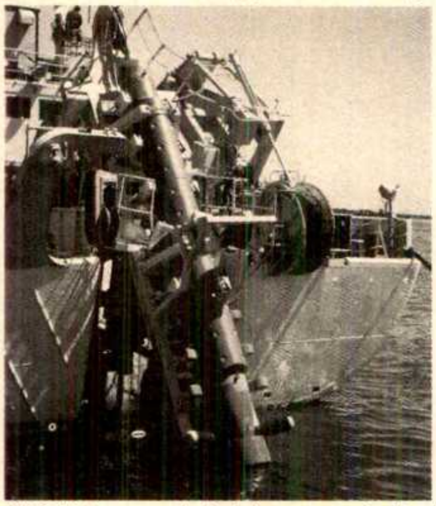
Economically, the sea-mounts may offer sources of strategic minerals, and the canyons and ocean-floor fans will interest the oil industry both as models of older sources of oil, and as possible drilling sites. There are no indications of sea-floor manganese nodules, but these were not expected so far north.

The survey, says Gardner, who headed the American side of the US–British team that did the work, will lead to half-a-dozen priority research projects for more detailed investigation, and already $60 million is inscribed in the USGS budget for fiscal year 1986 (yet to be approved) to pay for the work (over five years). This will be done jointly with universities, Gardner says.

In Britain, the excitement matches Gardner's, with the extra twist that the mission's success offers a real opportunity for British enterprise. GLORIA was developed at the Institute of Oceanographic Sciences (IOS) at Wormley, Surrey, and has a uniquely long range, which makes it extremely cost-effective for the survey of the 200-mile EEZs which almost every nation has declared since the 'Law of the Sea' agreement. According to Neil Kenyon of IOS, who with another British oceanographer Douglas Masson took charge of the British side of the recent GLORIA mission, GLORIA can perform an area survey 10 times faster than any competing system. It can survey an area half the size of Wales every day at a cost of $5 per square mile, IOS claims.

As a result there is now likely to be a flood of interest in using the torpedo-like instrument to survey EEZs around the world. Already USGS is negotiating for a further five years' work with GLORIA, says Gardner, starting next year in the Gulf of Mexico, and later covering Alaska and Hawaii; and, says Dr Tony Laughton, the director of IOS, to judge by reaction from the recent second international hydrographic technical conference in Plymouth, there are already indications of real interest in many other countries.

But that leaves IOS with an interesting problem. There is only one GLORIA. The USGS programme, if agreed, would occupy it nearly full-time. Apart from the interest of other nations, IOS scientists must have their own time with the instrument. And IOS funds, provided through the Natural Environment Research Council (NERC), are so short it would seem impossible to find the financial and human resources to build a second instrument, costing around £1 million. "If we were a commercial company, we would borrow money to build a new GLORIA on the prospect of making a profit", said Lawton. And, says IOS administrator Dr Tony Rees, "with ten GLORIAs we could cover the world in ten years".



GLORIA — geological long-range inclined ASDIC — is an acronym of an acronym. Dating from the second world war, ASDIC stood for "anti-submarine detection investigation committee". The acronym came to be used to describe the acoustic echo system developed in Britain to detect German U-boats. The achievements of GLORIA represent a 40-year development of ASDIC. The photograph shows GLORIA being launched from the Farnella *research vessel — a converted trawler.*

Treasury rules, under which NERC (and hence IOS) operate, make borrowing difficult. But since the present government is in favour of enterprise, Dr Lawton is hopeful something might be arranged. Other possibilities he is considering are to establish a private company to exploit GLORIA or to license the technology to an existing company. However, too much has been published about the instrument for it to be patentable, he thinks. The potential profits are large. But IOS will have to strike the right balance between commerce and science, says Lawton. "It clearly poses some big problems in terms of our role."

Robert Walgate

European solar energy

Off to sunny Sicily

Brussels

HELPED by the European Commission, a consortium of European companies will next month launch an experiment, in Sicily, to test four types of photovoltaic cells "in the field" for the first time. According to Commission officials, the data collected could play an important role in developing cheaper and more efficient solar cells.

The project will compare fixed and sun-tracking systems of monocrystalline and polycrystalline silicon modules, and two alternative modules: flat-plate amorphous silicon cells and concentrator gallium arsenide cells. The electricity produced by the 5 kW systems will be used in small local applications. The companies involved in the design and manufacture of the components are the Italian companies

BA gets under way

THE 146th annual meeting of the British Association for the Advancement of Science (BA) opened at the University of East Anglia in Norwich on Monday, with over 3,000 visitors expected — 700 more than last year's conference in Brighton. In recent years the BA has been seeking a new identity; it may have found it at Norwich in a mix of science popularization, science politics (whither Britain?), due concern for the place of science in the developing world, and increasing efforts to link science and industry in the minds of its visitors.

To paraphrase the outgoing president Sir Alastair Pilkington (the glassmaker) the BA represents an effort to put science to work in Britain: it has a utilitarian, constructive goal. According to the incoming president, biochemist Sir Hans Kornberg — a man closer to the cuts that British science has suffered recently — next year's BA meeting at the University of Strathclyde will see a greater emphasis on basic science (and perhaps a little more polemic on its behalf) than at Norwich.

But BA officers are very pleased with the £450,000 that Norwich has raised locally to support the meeting (covering more than half its costs) and with the buoyancy of the BA young scientists scheme (BAYS), with its 130 local branches (ever increasing) which hold local meetings throughout the year. And this year there is a new departure: the BA is launching a glossy new magazine, *Link-up*, edited by John Stansell, which will aim to link university science with industrial problems.

Robert Walgate

ENEL and Pragma, and MAN and Siemens of West Germany. Only a dozen or so European companies have been seriously developing solar energy components, including photovoltaic cells. In 1981, Europe had only a 12 per cent share of the world photovoltaics markets which then totalled 6 MWP (megawatts at peak). According to Commission estimates, the world market is expected to reach 400 MWP by 1990, and Commission officials believe that Europe could corner up to 40 per cent of that market. But Europe's main competitors, the United States and Japan, have a head start because of the extensive governmental support given to work on solar energy in those countries.

The solar energy industry is well-established in the United States. The photovoltaics market is worth an annual turnover of $55 million to the fifteen companies involved in component and systems production. The US research and development programme is extensive, while Japanese companies are forging ahead with the development of large-area low-cost amorphous silicon cells, encouraged by a MITI subsidiary, the New Energy Development Organization (NEDO).

National non-nuclear energy budgets in Europe are less generous to research in this field. Tax incentives to encourage the production of electricity using solar energy are becoming more and more frequent in the United States, but in Europe such stimulants have so far only been introduced in Denmark.

The European Community's non-nuclear energy research and development programme has contributed to bringing the cost of silicon cells down to one-fifth of their 1973 cost. According to those working in the field, the cost could be down to one dollar per watt by the year 2000.

However, the community's second pluri-annual programme came to an end in June 1983, while the ambitious budget of 379 million European Currency Units (2 ECU = £1) which the European Commission proposed for the third programme — a tripling of the previous budget — has been held up by the Community's unresolved budgetary wrangles.

In the meantime the delay continues to take its toll of research operations. Far-seeing officials earmarked funds from the 1979–83 budget to keep certain projects ticking over. But lack of funds in other projects will mean that research teams may be moved to other fields. Calls for tenders have also been delayed, so that it may be another year before work on new contracts can get under way.

In addition, extra investments allocated to the Community's advanced information technology programme (Esprit), launched this year, mean that cuts have to be made in other areas in 1984 and 1985. Solar energy research is no exception. The three largest EEC member states, West Germany, France and the United Kingdom, have opposed the draft budget proposed by the Commission at successive research councils. The proposal is not likely to fare any better when the ten's research ministers take their next look at it in mid-October.

The potential of photovoltaics is reflected in the funds earmarked for it under the third non-nuclear energy research and development programme proposed by the Commission — half of the solar energy sub-programme (80 million ECU) which also includes developing solar architecture, passive solar heating and cooling systems, and instruments for analysis, testing solar energy systems and looking at the problems of storage and performance.

As far as photovoltaics are concerned, the Commission wants to lower the costs of cells and develop competitive large-area power supply systems during the next four years. The second area of priority is biomass. It is estimated that the conversion of biomass could eventually provide 5 per cent of the Community's energy requirement, and half a millon extra jobs. The Community has a 38 per cent energy deficit at the moment. Eight of the ten member countries have to import between 48 per cent (Greece) and 81 per cent (Italy) of their energy requirement from abroad — the two energy exporters are the United Kingdom and the Netherlands.

The third area on which research is to be concentrated is geothermal energy. The Commission has proposed spending 39 million ECU to develop low temperature source applications, and look at the problems of reservoir management, fluid extraction, energy conversion and develop the feasibility of the hot dry rocks process.

The final area of research and development is wind energy. In addition to monitoring the performance of some 200 wind generators, which are scattered throughout the ten member states, Community research would be centred on the development of multiwatt machines, the improvement of blade design and engineering, improving the technology of small and medium sized machines, solving the problems of site aerodynamics, subsystem concepts and integration into the overall electrical supply system.

Anna Lubinska

Science in India

In the special issue on science in India (*Nature* **308**, 581-600; 1984), in an article dealing with the administration of research (pp.591 *et seq.*), there is a reference to an academic's complaint that he had to negotiate with his university to spend Rs100. The same paragraph mentioned the Madurai Kamaraj University, and the vice-chancellor, Dr J. Ramachandran, asks us to point out that the reference was not to his university. □

Mongolia

New man backs science

The new general secretary of the Central Committee of the Mongolian People's Revolutionary Party, Dr Jambyn Batmonh, is something of a rarity among communist leaders. The usual route to political power involves rising through the ranks of the party or military apparatus. But Dr Jambyn is a former academic with good links with the scientific community.

Educated at the Mongolian State University and at the Academy of Social Sciences of the Central Committee of the Communist Party of the Soviet Union, Dr Batmonh worked for more than twenty years in Mongolia's higher education system. In 1967 he became pro-rector, and subsequently rector, of the Mongolian State University.

In 1973, he transferred to party work as head of the central committee's Department of Science and Education. In 1974, he became chairman of the Council of Ministers of the Mongolian People's Republic. Given his background, it is not surprising that his inaugural speech as general secretary stressed the importance of science and technology in raising the efficiency of Mongolian agriculture and the need to improve education and health facilities.

Dr Batmonh — academic makes good.

The son of north-Mongolian cattle-herders, Dr Batmonh's *curriculum vitae* illustrates the rapid development of education in Mongolia which (apart from lamasery schools) began only five years before his birth with the foundation of a 40-pupil elementary school in Urga (now Ulan Bator). The Mongolian State University was founded only in 1942 and the Mongolian Academy of Sciences in 1941. As a result of the lack of opportunity at home, a strong tradition has developed that Mongolian scholars do at least a part of their postgraduate studies in the Soviet Union, and in many fields of research, including the application of radioisotopes, the development of the Mongolian chemical industry and the geophysical survey, Soviet scientists continue to play an important role.

Vera Rich

Siberia

Canals to feed saline lake

SOVIET plans to divert the north-flowing Siberian rivers southward have received a new impetus, with the launch of a scheme to replenish the waters of the landlocked Aral Sea. Increasing irrigation demands on the Rivers Amudarya and Syrdarya which feed the Aral have led to a drop in the water level of 3 metres in the past two decades. The consequent rise in salinity has had an adverse effect on the fish-stocks of the lake.

As the Aral basin is the main source of Soviet cotton and the 1982 Food Programme envisages further irrigation projects in the area, a massive rescue operation has been planned, requiring the construction of a 2,550 km canal from the confluence of the Ob' and Irtysh rivers to the Amudarya. This will not only replenish the Aral Sea to its optimum level, but also permit the irrigation of an additional 4 million hectares of land. The fall in water-level is undoubtedly worrying to ecologists, who, until the canal is ready, plan to regulate evaporation losses by building two dams, which will cut off Adzhibai Bay and the gulf known as the Little Sea and thus keep those areas close to the river mouths at a salinity level suitable for fisheries.

Dam-construction in Soviet seas is, however, a sensitive issue. A dam completed five years ago, which was meant to halt evaporation losses in the Caspian Sea has instead caused disastrous changes in the subterranean brines which form the feedstock of the Karbogazsulfat chemical industry, and have turned the region east of the gulf into a salt desert. (The Caspian level, meanwhile, has risen through apparently natural causes.)

The proposed use of the Irtysh water for the diversion scheme, too, is not without its problems. Although the proposed canal will draw off only 6 per cent of the Ob'-Irtysh water resources, even this small proportion could raise difficulties. Recently there has been a continuing dispute on the upper Irtysh between the farmers, fishermen and river-boatmen who depend on a plentiful water-supply, and the Kazakhstan Ministry of Land Reclamation and Water Resources which withheld supplies at the request of the electrical generating authorities. According to *Kazakhstanskaya Pravda,* there have been serious planning errors in the construction of hydroelectric works on the upper Irtysh which will require further major engineering works to put right. Yet all public statements on the proposed canal to the Amudarya tacitly assume that the Ob' and Irtysh have no difficulties with their "water budgets".

The emphasis on the small percentage of water to be drawn off by the canal, and the consequent assurances that its diversion will not affect the ecology of the region is a fairly new approach. Earlier plans spoke grandiosely of turning whole rivers back in their courses. When, however, the schemes were revived in the early 1970s, there was a worldwide outcry from ecologists, who feared that the loss of water to the Arctic Ocean might change the world's weather patterns. The Soviet planners issued vehement denials that such a disaster might occur, but postponed their plans until further surveys could be carried out.

As a result, they have introduced a major modification into the "diversions" announced during the 1970s. The plan originally involved replenishing the feeder rivers of both the Azov and Caspian Seas. To do this, however, would necessitate the transfer of more than 20 km^3 of water a year, too great an amount, according to planners, for the environmental changes to be predictable. (The Amudarya canal will transfer 27.2 km^3 a year.) Accordingly, it was decided to concentrate on the Caspian, not only because its present "water-budget" is still fairly close to equilibrium as regards inflow but also because of the particular economic importance of the Caspian as the largest producer of sturgeon in the world.

Vera Rich

UK research

Councils hunting for heads

BRITISH research councils appear to be increasingly hamstrung in their attempts to recruit new chief executives, at least in part because suitable candidates now consider senior positions with the research councils to be uncomfortable beds of nails. Three of the five councils will need to appoint new chairmen within the next twelve months.

The Natural Environment Research Council is in the most urgent need now that its chairman for the past three years, Sir Hermann Bondi, has become Master of Churchill College, Cambridge. Apparently the council has been rebuffed by the two candidates first approached, but has now recommended (to the Secretary of State for Education and Science) that Dr Hugh Fish, chairman of the London Water Board and one of its own members, should be appointed chairman on a short-term basis.

The Agricultural and Food Research Council, whose secretary Sir Ralph Riley is on the point of retirement, is by contrast using the services of an executive recruitment agency to appoint a successor. By all accounts, however, the Science and Engineering Research Council plans to go one substantial step further and to use a head-hunting company as a means of identifying possible candidates. In this case, there is a suitable breathing space. The present chairman of the council, Professor John Kingman, is due to become vice-chancellor of the University of Bristol only at the beginning of the academic year 1985-86. □

Defence department money on offer

Washington,

THE US Department of Defense is putting its money where its mouth has been on biological warfare, and a major beneficiary may be academic researchers. A series of full-page advertisements have recently appeared in *Science* magazine, placed by the US Army Medical Research Acquisition Agency, calling for proposals in a broad range of areas related to protection against biological agents.

A spokesman for the US Army Medical Research Institute of Infectious Diseases (USAMRIID), the old biological warfare establishment at Fort Detrick, Maryland, said that the solicitations are part of a general effort to expand its research programmes on biological defence in four areas: parasitic diseases, low-molecular-weight toxins, rickettsial diseases and bacterial diseases. The most recent advertisement seeks research proposals on biochemical, immunological, genetic, pathophysiological and therapeutic studies of bacterial diseases, with special emphasis on anthrax, botulin, diarrhoeal diseases and "other bacteria or toxins capable of eroding combat strengths" or "agents of potential biological warfare importance".

The USAMRIID spokesman said that the advertising campaign was simply a way of letting scientists who are probably already familiar with the institute's work learn how they can submit proposals. All of the work is unclassified.

Support for USAMRIID has risen dramatically in the past few years, from $17 million in fiscal year 1982 to approximately $40 million this year. The current plan is to double that figure over the next three years. The entire Army Medical Research Command, of which USAMRIID is a part, is now spending more than $100 million a year on extramural research, although this figure includes not only biological warfare defence research but other topics relating to soldiers' health.

The USAMRIID spokesman attributed the new emphasis on medical research both to a heightened concern with preparedness — the Secretary of Defense, Caspar Weinberger, has cited medical care as a critical element in US war-fighting capability — and also to the biological warfare threat perceived in the Soviet Union's supposed proxy use of "yellow rain" in South-East Asia.

Stephen Budiansky

US agricultural research

Competition reaps rewards

Washington

A STUDY of US agricultural research now being circulated to colleges and universities offers encouragement to scientists and may pave the way for more coherent planning. The report* emphasizes the need for improved communications between Congress and the executive so that scientific projects do not become hostages to political fortune, and may lead to an expansion of competitive grant funding. This would bring benefits to the underdeveloped plant biotechnology research programme.

The timing of the report is apt: next year's agriculture appropriations bill remains jammed in Congress. The Senate has restored the administration's $50 million budget request for the Department of Agriculture's competitive grants programme after the House sought to cut this to $17.5 million. The $50 million includes $28.5 million allocated to the administration's new biotechnology initiative. Although no conference committee has yet been appointed to bridge the gap, much behind-the-scenes negotiating is going on. But despite the generally favourable light in which science is regarded in Congress, prominent figures in the House consider basic research in agriculture irrelevant to the immediate needs of farmers.

The report now being circulated was prepared under contract for the Department of Agriculture as an "action research programme", involving scores of interviews. It is heavy with sociological theorizing and even ventures some speculations on philosophical issues: for example, the "logical positivistic" underpinnings of agricultural research are blamed for the "paradox of faith in science leading to doubt and distrust". But there are also some more concrete suggestions, chief among which is a proposal for a new National Agricultural Issues Commission based within the National Academy of Sciences which would define long-term research goals.

Ironically, that proposal is the one that seems least likely to get anywhere. A majority of the key decision makers who reviewed a draft of the report felt that two existing bodies — the Joint Council on Food and Agricultural Sciences and the Users Advisory Board — could do the job.

Many of the report's other conclusions have been well received, although a proposal for new centres of excellence in agricultural research is contentious. The report urges efforts to broaden recruitment to bring in more students from non-farm backgrounds, and argues for increased prominence and status for scientists. A separate study being completed by Professor Irwin Feller of Pennsylvania State University, shortly to be delivered to the agriculture department, is thought to have a similarly up-beat approach towards future contributions of research.

The combined impact of both studies is likely to have a "slow but significant effect" on policy, according to Dr John Jordan, administrator of the agriculture department's cooperative state research service. The activity of recent months has brought together congressmen and scientists "who would never normally see each other". The use of competitive grants to fund research is now likely to increase, thus allowing major research centres outside the land-grant system to make bids. And even the land-grant colleges are starting to make more use of competitive schemes and joint schemes with non-land-grant institutions, says Jordan.

Tim Beardsley

The Paradox of Success: The Impact of Priority Setting in Agricultural Research and Extension, (US Department of Agriculture).

New US genetics centre goes west

San Francisco

A NEW research centre concerned with genetic engineering of crop plants has been established jointly by the US Department of Agriculture (USDA) and the University of California. The centre hopes to attract university and industry researchers from all over the world to work on basic research projects in plant genetics and gene expression.

The Plant Gene Expression Center, with an initial annual budget of $4 million, will be housed in USDA's Western Regional Research Center in Albany, near the Berkeley campus of the university. The facility has laboratory space for about 40 researchers and is expected to be operational within a year. Ten senior scientists will form the foundation of the centre, including two senior scientist programme leaders holding university appointments. The remaining eight core scientists will hold positions with USDA's Agricultural Research Service (ARS).

The core group will be supported by a consortium of public and private researchers. The consortium serves as a source of expertise and provides an important link with other research institutions and industry. In addition, a science advisory committee will be formed to help set research priorities.

The centre will investigate basic questions in plant molecular biology, using and further developing new tools of plant genetic engineering. The centre wants to make its research findings available to anyone, including those interested in developing marketable products. Details of publication policy have not yet been worked out, according to Gerald Still, acting director of the centre. Usually the centre will follow the ARS practice of establishing public patents and refusing industry support that stipulates secrecy and exclusive rights. Dr Still, formerly National Program Leader at ARS in Beltsville, Maryland, has the task of coordinating research activities, arranging cooperative agreements and recruiting financial support. He hopes to supplement the annual budget provided by ARS with grants from other public and private agencies and industry.

Roman food not so fast

SIR — As a pioneer in the study of animal remains from archaeological sites, I counsel caution in concluding that a high proportion of pig bones indicates the decline of Rome into a fast-food empire (*Nature* 17 May, p.211). First, the bones indicate the proportions in which the different species were eaten rather than kept. Although in a peasant economy the two are probably the same, it is noteworthy that whereas the Cistercian monks kept thousands of sheep but relatively few cattle, 90 per cent of the medieval bone remains from Kirkstall Abbey were from cattle[1].

Although it is true that the greatest proportion of pig bones from a Roman site in Britain (for comparison) was 26 per cent, the figures of 40 per cent and even 65 per cent pigs quoted by Hodges from Italy hardly indicate overwhelming predominance when one notes that cattle remains ranged up to 78 per cent and sheep remains up to 95 per cent on Roman sites, again in Britain[2].

The term "fast food" used by Hodges is used in a modern context for food preparation rather than for food production. Since the pig was a scavenger in the past, pork was certainly cheap to produce, but not "fast" or "short term" as Hodges implies, since until after the Middle Ages pigs were slow-maturing animals. If the production of pigmeat is relatively "fast" today (as a major component of "fast" or convenience foods) it is because pigs have been bred for early maturity and are fed concentrated cereal-based diets.

2. Ryder, M.L. "Livestock" in *The Agrarian History of England and Wales* Vol. 1, Pt 1 (ed. Piggott, S.) (Cambridge University Press, 1981).

Richard Hodges replies:

SIR — Dr Ryder is making a mountain out of a molehill. My short review in *Nature* placed in a wider historical context a collection of recently published studies by archaeozoologists, in whom I have every confidence.

First, I made exactly the point (the main thrust of my note) that it was consumption of pig rather than any assumptions about production directly that made the data so historically interesting. I agree with him. However, I suspect his Kirkstall Abbey example is a poor illustration of his point, since I would imagine his high cattle bone is merely an indication of the sampling procedures (or lack of them) used when the site was excavated.

Second, I do not follow his point about Roman sites in Britain. To make such comparisons without considering historical and ecological contexts for the sites concerned is quite unscientific.

Third, I like the term "fast-food", suggested to me by your assistant editor. Of course, Ryder is strictly right. The term should have been qualified — and would have been in a *long* article — by precisely the comments he makes, effectively endorsing the reason for drawing attention to high pig numbers in the first place.

Cancer incidence at Sellafield

SIR — The investigation by Sir Douglas Black (see *Nature* 26 July, p.263) into the alleged increased incidence of cancer in West Cumbria usefully suggested what further research is needed, especially the measurement of radiation dose actually received and whether metabolic differences between children and adults alter the effects of radiation. However, on the evidence already available, doubts must be raised about the report's judgement that the incidence of leukaemia in Seascale is "unusual but not unique".

Ward rank order	Cases	Children	Poisson probability	Rate per 1,000
1*	4	411	0.0001	9.73
2	4	976	0.0032	4.09
3	2	144	0.0036	13.88
4	4	1,207	0.0068	3.31
5	4	1,353	0.0100	2.95

Top five wards ranked by Poisson probability for incidence of lymphoid malignancy in under 15 year olds, 1968–82 (from Craft *et al.*[2]).

*Seascale.

The report examines the occurrence of lymphoid malignancy, in children under 15, in the 765 electoral wards of Cumbria, from 1968 to 1982. Incidence in the wards was ranked by rate per 1,000. Seascale (9.73/1,000) is ranked third. Although well above average (0.61/1,000), Seascale appears to lie within the normal pattern of variation.

However, rate so measured is an uninformative index. As most wards have only 0 or 1 cases, all that is reflected in rate is ward size, which varies twenty-fold (from 100 to 2,000). A more appropriate measure is the cumulative Poisson probability. This gives the probability of occurrence in a ward of 0,1,2. . . cases, if the cases are randomly distributed in the region. The incidence seen in Seascale is 1.3×10^{-4}, which when ranked lies first (see table and ref. 2). This incidence is expected to occur once in a sample of 8,000 wards.

Even more disturbing are the two further cases of lymphoma registered in Seascale in 1983 (ref. 1). By updating the survey to 1983, the Poisson probability for such an occurrence falls to approximately 1.0×10^{-6}. This can only be described as unique, lying well beyond the expected variation.

The two simple points raised here must make the "qualified reassurance" given by the Black report less acceptable. Seascale has an extraordinarily high incidence of lymphoid malignancy. Its proximity to the Sellafield reprocessing plant, a potential source of mutagenic radiation, is disquieting.

Too many papers?

SIR — For some years there has been talk of there being too many scientific journals but now it appears that there are too many papers. An informal sampling suggests that, in science and medicine, journals of reasonable status are experiencing an increase of around 10 per cent in submissions while editors in the area of whole organism biology or traditional life science disciplines have reported increases of up to 30 per cent, and even 50 per cent in the case of certain high status titles.

There are several possible explanations. (1) A demographic factor; as a result of the growth in tertiary education in the 1960s, a large number of scientists are now in their most productive period and could be making a last effort to gain promotion. (2) Support of research in some areas, especially "soft" science, has been severely cut, heightening the struggle for grants. (3) Information technology has made it easier to store and process research data. This could be having an effect in astrophysics and geophysics in particular. (4) The decline in the publication of multi-author review volumes, resulting from library cutbacks, may have diverted longer review articles, or just the writing effort involved, towards refereed journals.

At present, smaller journals are being forced to restrict page budgets and there is the prospect of worthwhile if specialized papers going unpublished. Whatever the underlying reasons for the apparent increase in papers, the signs indicate a developing problem in the publication of research, especially in non-commercial areas such as ecology.

Brownian and quantum motion

A recent demonstration that a classical problem in brownian motion belies Dirac's relativistic equations of quantum mechanics is a reminder of many things that students should be taught.

THE connection between brownian motion and quantum mechanics should be better known, at least to those brought up in the days before the full implications of Feynman's reformulation of quantum mechanics (in 1948) were fully appreciated, perhaps 15 years ago. That will be people's reaction to the neat argument, now published by B. Gaveau *et al.* (*Phys. Rev. Lett.* **53**, 419; 1984) which sets out to provide a demonstration that Dirac's relativistic wave equation can be derived from a consideration of a simple classical problem in brownian motion. Others will however note that the authors include Mark Kac, now at the University of Southern California, Los Angeles, who first derived the Schrödinger equation from a brownian motion problem in 1959, as well as T. Jacobson (University of Texas, Austin) and L.S. Schulman (Technion, Haifa), who have more recently made important contributions to similar problems.

The starting point for the argument is simple but evocative. Consider a particle moving in one dimension only at some fixed velocity, and let it suffer reversals of direction at random intervals, themselves distributed statistically according to some suitable law, most simply a Poisson distribution. Practitioners in brownian motion problems will readily write down expressions for the probability density (per unit length and per unit time) that the particle is at some place along the line at a certain time, and moving in one direction or the other. Most simply, there is a different function for each direction. The next step is to relate these probability densities to each other by taking account of the conservation in number of the particles moving along the line. The outcome is a set of differential equations which must be satisfied by the two probability densities. (In the sequel, these correspond to the two states of chirality or handedness which alone are accessible to relativistic Dirac particles in one dimension.) What the authors assert (and then prove) is that these equations are in an appropriate sense equivalent to Dirac's equation in one dimension. They then show that the same technique can be extended to the full relativistic problem (with three space dimensions).

The origin of this problem is intriguing, for it seems first to have appeared as an exercise for students in the elegent textbook *Quantum Mechanics and Path Integrals*, by R. P. Feynman and A.R. Hibbs, published in 1965. There, users of the book are invited to calculate the evolution in time of a system consisting of a particle moving with the velocity of light in a single dimension, and suffering random reversals of direction. To Feynman and Hibbs, this would merely have been a test of what students had been told in the first thirty pages of the book. To Kac and company, the challenge has been to demonstrate that the connection between quantum mechanics and brownian motion that applies in non-relativistic mechanics also applies to Dirac's equation. That they succeed will not surprise those already in the know.

For the rest of us, there are several missing elements of which the least excusable is Feynman's use of the concept of the path integral. That, of course, is also familiar from classical mechanics. Since de Maupertuis and the principle of least action in the eighteenth century, it has been understood that the path that will actually be followed, and which is thus that dictated by the laws of motion, will be that for which the action (force multiplied by time) is least. For simple systems, forces can be calculated as a function of time from the function of the system called the lagrangian, essentially the difference between the kinetic and potential energies. Given initial and final states, and starting and finishing times, it is then possible to calculate (in principle at least) the action for all possible paths and to choose that for which the action is least.

The difference between this and quantum mechanics is that there is no unique path for the evolution of a system but that all possible paths must be counted. As Bohr and his disciples were always telling us, a photon confronted with two slits in a screen cannot be said to use one slit or the other, but both.

Each path is relevant; the only meaningful question to ask about the outcome is not where the particle finishes up, but the probability that it should finish up here or there and, to that end, that it is necessary to add together probability amplitudes (one for each possible path), taking account of plus and minus signs, and of imaginery as well as real parts, before calculating the probability (by squaring the amplitude). The essence of Feynman's quantum mechanics is a powerful prescription for calculating the evolution of the amplitude for each possible path. Inevitably, the outcome is a line integral. Although the integrals are not the same as those appearing in classical mechanics, their relationship is plain to see. In passing, it is worth asking whether quantum mechanics would ever be presented to students in other terms, necessarily less direct, if it were not that so much energy had been invested in teaching them to solve differential equations.

The connection with brownian motion is harder to discern. The formal resemblance with quantum mechanics is simple enough. Because the process is statistical, the most one can hope to do is to calculate the probability that a particle starting from one place on the line will finish up at another. Thus, if a particle is to start at one place and finish at another after a specified length of time, there is a large (even infinite) number of paths which it may traverse in doing so. The first to recognize this deeper relationship with Feynman's quantum mechanics — the existence of a multitude of paths — seems to have been K. Ito, working on brownian motion in 1951.

In reality a connection between the quantum mechanics of brownian motion gets even more specific. Put briefly, while the probability amplitudes in the brownian motion problem are all real and positive (and are thus simply additive), those which conspire in the calculation of Feynman's propagation functions are not. The quantum version of the calculations can be turned into the other version simply by replacing *i* (the square root of minus 1) by minus 1 whenever it occurs. The similarity is even more striking when one sees it demonstrated that a specific path in Feynman's formulism can be boiled down to calculating the chances that a brownian particle makes its way along the same such trajectory by random process.

The implication is simply grasped. The propagation of the probability amplitude along an arbitrarily chosen trajectory is indeed to be likened to brownian motion. One of the quirks of that process, the fact that the average displacement of a particle is proportional to the square root of the time elapsed, accounts for some of the computational complexity of Feynman's formulism. Taken together, the whole box of tricks makes it intelligible that there should be a correspondence between the theory of quantum fields and that of phase transitions on a lattice. This is yet another part of the case for changing tack on teaching.

Oceanography

Windscale effluent as a tracer for continental shelf circulation

from J.T.F. Zimmerman

CONCERN about the radioactive effluent from plants reprocessing nuclear fuel, primarily Sellafield (formerly Windscale) in Cumbria, UK, and to a lesser extent Cape la Hague near Cherbourg, France, has led to regular surveying, over more than a decade, of the radioactivity of the west European continental shelf waters, particularly by the Fisheries Research Laboratory in Lowestoft, UK, and by the Deutsche Hydrographische Institut in Hamburg. The results of the survey are not simply a means of monitoring a pollutant, but can be put to scientific use. As the flushing time scale of the Irish Sea–North Sea–English Channel system is of the order of several years, the outfall should by now have spread over the entire area. Tracing the fate of the radionuclides should therefore provide a method of testing hypotheses about the general circulation of these shelf seas. In a recent paper, D. Prandle of Bidston Observatory, Merseyside, UK, uses the radionuclide data to provide a numerical model of the water circulation of the area[1].

The radionuclide caesium-137 is an ideal conservative trace because its half life of about 30 years is long compared to the transport time scales on the shelf and because, being highly soluble, it is not easily removed from the water column by sedimentation. ^{137}Cs does not occur in nature. By the time the discharges from the reprocessing plants started, however, nuclear bomb tests had already created a background level in the Atlantic Ocean of 0.14 pCil^{-1}, rising to 0.4 pCil^{-1} in the North Sea[2]. The latter level has now been increased to 1–5 pCil^{-1}, though this is still well below the permissible limit of 900 pCil^{-1} set by the International Atomic Energy Agency[3].

What can be learned from the spread of ^{137}Cs over the contaminated shelf and even beyond that in the arctic waters of the North Atlantic Ocean? Early surveys[2-4] already confirmed the traditional view[5] of major transport routes of the water masses in the North Sea, Irish Sea and English Channel. Thus, generally, water from the Atlantic Ocean enters the English Channel, where its splits into two branches, one of which flows through the Straits of Dover, along the Dutch, German and Danish coasts to the Skagerrak area and finally is removed to the northern Atlantic Ocean by a northward current through the deeper Norwegian trench. A second branch splits off between Cornwall and Ireland, flows northwards through the Irish Sea, turns around Scotland, mixes with Atlantic water and then enters the North Sea near the Shetland–Orkney Islands. From there it flows southwards in a broad band on the western side of the North Sea to about 53°N, the latitude of the Wash, where it finally joins the flow from the Straits of Dover.

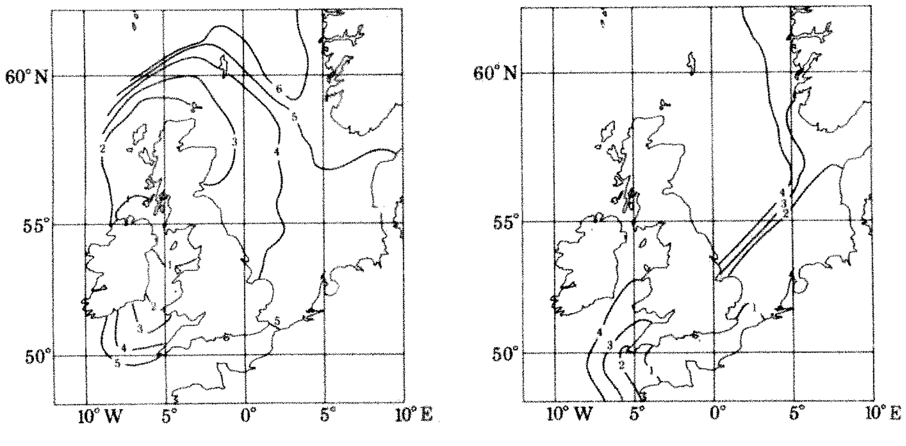
The distribution of radioactive effluent shows[2-4] that the discharge from Windscale enters the North Sea through its northern entrance and gradually spreads over all of its area before being flushed to the northern Atlantic Ocean, whereas that from Cape la Hague primarily influences the eastern side of the North Sea basin.

What are the velocities along these pathways? What is the dilution rate of a patch that follows a specific transport route and what kind of mechanism drives circulation and diffusion? Some of these questions could be tentatively answered by looking at the evolution with time of the ^{137}Cs distribution pattern[2-4] or by using simple box models for subregions of the shelf, particularly the North Channel and Irish Sea[6-8]. In a much more ambitious use of the ^{137}Cs data, Prandle has now employed the recorded time evolution of the ^{137}Cs distribution over the continental shelf to calibrate a complete two-dimensional (vertically integrated) numerical model of its water circulation.

The model supports the 'traditional view' of the general circulation but also, more importantly, identifies the primary driving forces of the water movement and their relative strength. Thus, Prandle shows that windstress over the area, which is, on average, southwesterly in direction, sets the water on its course and that this circulation is reinforced and its speed increased by 10–50 per cent, by tidal rectification. Together, these driving forces create a more or less steady current with velocities of 1–6 cm s^{-1}, giving annual displacements of 500–1,000 km along the transport routes described above. This gives a transit time of 5 years for the Cornwall–Skagerrak route that passes the Irish Sea and recirculates into the North Sea and about half that time for the 'direct' route through the Straits of Dover.

Advection by currents is only half of the story, however. The tracer is also diffused by turbulent eddies, which cannot be resolved by a model. Turbulent diffusion coefficients have, therefore, to be introduced and it is here that the observed ^{137}Cs distribution can be used for calibration. The best way to parametrize turbulent diffusion coefficients in these areas is controversial. Prandle prefers to express them in the tidal current velocities, probably the safest choice. Calibration of the model with the aid of ^{137}Cs data gives values for the diffusion coefficients ranging from 50 m^2 s^{-1} for the quiescent regions of the central North Sea to 600 m^2 s^{-1} for the 'turbulent' Irish Sea. Thus, advection dominates diffusion over much of the North Sea area, whereas in the Irish Sea and English Channel the two transport processes are equally important.

Once supplied with diffusion coefficients, Prandle's model is able to predict a variety of time scales for the flushing of the shelf waters and the discharges from Windscale and Cape la Hague. It predicts that effluent from Windscale takes about 4 years to travel around the North Sea before entering the Atlantic Ocean through the Norwegian trench. The calculated bimodal distribution of transit times for Windscale, however, suggests that after 1 year about one-third of the discharge has escaped to the Atlantic Ocean by mixing during its passage through the waters around northern Scotland. The discharge from Cape la Hague — which is an order of magnitude less than that from Windscale — needs about 2 years to reach the Skagerrak via the



'Age' distribution (in years), as calculated by Prandle[1], for the effluent of Windscale (left) and Cape la Hague (right), where the 'age' of a constituent of a watermass is the average time it needs to travel from its discharge position to another arbitrary position in the area of consideration.

eastern North Sea. These values are of course related to the *e*-folding time for flushing of separate basins by the fluxes through their boundaries. For the North Sea and Irish Sea as a whole, Prandle's estimates for these scales are 530 and 328 days respectively.

For various subregions of the North Sea it is tempting to compare Prandle's estimates of the flushing time scale with those reported last year[9] by a working group of the International Council for the Exploration of the Sea (ICES) led by L. Otto from KNMI, de Bilt, Netherlands. There are notable discrepancies: ICES observations suggest much more stagnant water masses along the east coast of England and in the centre of the North Sea gyre and more rapid flushing in the deep Norwegian trench than are predicted by Prandle's model (and others). Clearly the details of the circulation pattern are still open to question; nonetheless, Prandle's tuning of a circulation model with a suitable tracer has improved our understanding of the west-European shelf.

What happens to the radioactive effluent once it has left the shelf? At a recent symposium on 'Contaminant fluxes through the coastal zone' held in Nantes in May, Dahlgaard and co-workers from the Riso National Laboratory, Denmark, and the University of Lund, Sweden, presented an updated version[10] of their earlier conclusions[11] that the Windscale effluent reaches the East Greenland Current in about 6–8 years, probably after being transported northwards along the Norwegian coast and across the Atlantic south of Spitsbergen. Although crude, this picture fits in very well with Dahlgaard's results for the North Sea. These predict transport times and a dilution rate of the Windscale effluent as follows. If its concentration is set at 1,000 in the northern Irish Sea where the material stays for 1 year, say, it will take about 3 years to cross the North Sea during which time its concentration drops to 100. The passage along the Norwegian coast takes another year, with a dilution of another 50 per cent, and by the time the material reaches the waters near Greenland, within 2–4 years, its concentration will be about a thousandth of its original value. ☐

Molecular biology

Excision of introns in lariat form

from Charles Weissmann

SEVEN years after the discovery that the protein-coding sequences of most genes are disrupted by introns, an astonishing pathway has been revealed for the splicing (that is, excision) of introns from gene transcripts. In short, both Sharp's group[1,2] and Maniatis, Green and their colleagues[3] have shown that, contrary to expectation, the introns that are excised in the production of messenger RNA (mRNA) from its precursors (ultimately the gene transcripts) are recovered as lariat-like structures rather than as linear or circular RNA. The lariats are formed by attachment of one end (5′) of the intron to a site close to the other (3′).

This discovery has followed the recent development of cell-free systems for the splicing of preformed mRNA precursors[4-6]. As a substrate for their cell-free system Sharp and his colleagues used a ^{32}P-labelled RNA, prepared by the Manley system[7], that consisted of the major adenovirus 'late' exons (L1 and L2) separated by an abbreviated intron and with a short second intron following L2. This substrate is schematized as 'S' in Fig. 1. Earlier this year they had reported[4] that prolonged incubation of the substrate with a HeLa cell extract in the presence of ATP and Mg^{2+} gave rise to four major products (now identified as structures II to V in Fig. 1), three of which accumulated, while one (II) appeared transiently with the kinetics expected of an intermediate. The sequences of these products were investigated by fingerprint analyses and hybridization experiments. III was one of the expected splice products, with L1 joined to L2 and followed by the second intron; V resembled III but lacked most or all of the second intron (it is believed to be a degradation product of III).

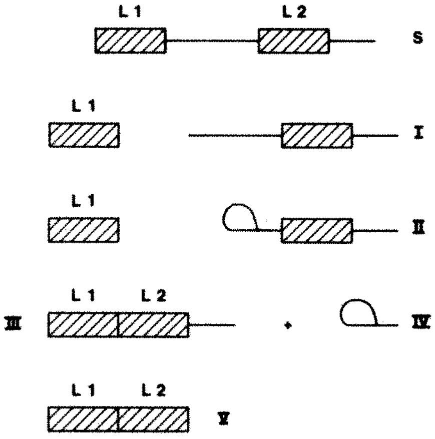

Fig. 1 Structures of the products (I–V) of cell-free splicing of a substrate (S) RNA composed of two exons (L1 and L2) and two introns. IV is the excised intron in lariat form.

As judged by its oligonucleotide map, IV corresponded to the intron, but it showed two unexpected features. First, it had an abnormally low electrophoretic mobility for its molecular weight and when subjected to limited RNase T$_1$ digestion gave rise to a discrete product with a lower mobility. Second, its complete digestion by RNase T$_1$ gave rise to a modified oligonucleotide not present in the precursor RNA. The putative intermediate II contained the sequences of the first intron, the second exon and the second intron; it too showed an abnormal mobility and was digested by RNase T$_1$ to the same modified oligonucleotide as IV. The modified oligonucleotide resisted complete digestion by nuclease P$_1$, suggesting to Grabowski *et al.* that it might contain a branchpoint of the kind previously found in total polyadenylated nuclear RNA by Wallace and Edmonds[8], who, interestingly, suggested that the branched RNA species could be splicing intermediates. To explain its properties, Grabowski *et al.* suggested that IV contained a circular moiety.

The new papers by Padgett *et al.*[2] and Ruskin *et al.*[3] show beyond reasonable doubt that product IV and putative intermediate II have the lariat-like structures indicated in Fig. 1. The additional evidence offered by Padgett *et al.* for the structures of IV and II is as follows: the intron-derived product IV has a free non-phosphorylated 3′ terminus; complete digestion of the modified oligonucleotide with RNase T$_2$ gives rise to a nuclease-resistant oligonucleotide, namely 2′, 3′-ADP linked to two nucleotides (presumed to be 3′-UMP and 3′-GMP) by 3′–5′ and 2′–5′ phosphodiester bonds respectively, as shown in Fig. 2; and in both II and IV, the 5′-terminal region of the intron is linked to the modified oligonucleotide, which contains the sequence running from nucleotides 19 to 32 upstream of the 3′ splice site.

Ruskin *et al.*, employing a technically distinct approach, used as their substrate a truncated β-globin RNA, prepared by the SP6 RNA polymerase system[9] and consisting of the first exon, the small intron and part of the second exon, to which was added a 5′ cap using vaccinia virus guanylyltransferase. With an extract of cell nuclei as the source of splicing activity, the species corresponding to I (mentioned in passing by Sharp and his colleagues) and II were produced during the early stages of the reaction, while those corresponding to III and IV accumulated later. Ruskin *et al.* characterized the lariat-like structures on the following basis: first, reverse transcriptase elongation of a primer complementary to a segment of the second exon was blocked about 37 nucleotides

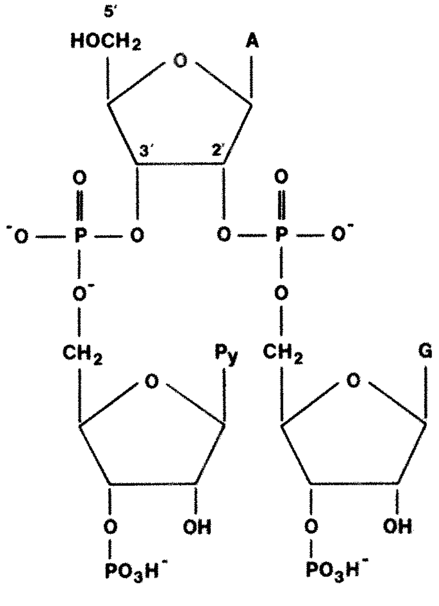

Fig.2 Digestion product of the modified oligonucleotide formed at the attachment site of the lariat-like structure of an excised intron.

upstream of the 3′ splice site, while a primer complementary to a segment of the first intron upstream of the block was elongated to the 5′ end of the intron; second, when (and only when) an oligodeoxyribonucleotide complementary to the intron was hybridized to the globin counterpart of IV, RNase H treatment led to a strong shift in electrophoretic mobility but did not give rise to a second RNA fragment, showing that cleavage must have occurred within a circular entity (an analogous result was obtained for intermediate II); third, a nuclease-resistant branched oligonucleotide with the structure shown in Fig. 2 (where Py = cytosine) was characterized, and the branchpoint located at the thirty-seventh nucleotide upstream of the 3′ splice site.

What does all this mean? It is quite likely that products I and II represent intermediates on the way to the final product. The suggestion is that splicing involves cleavage at the 5′ splice site of the intron, yielding a 5′-phosphorylated guanosine residue at the 5′ terminus of the intron which then becomes joined to the 2′ hydroxyl group of the branch acceptor nucleotide (an adenosine residue) within the intron. The reaction may be concerted in the sense that the attack of the branch acceptor site on the 5′ terminus of the intron cleaves off the first exon while forming the lariat. In the next step, the cleaved 3′ end of the first exon, which is presumed to remain bound to a putative splicing complex, attacks the phosphate between the last (3′) nucleotide of the first intron and the first (5′) nucleotide of the second exon, releasing the intron as a lariat while joining the two exons.

Several questions are raised by the new findings. Are there further intermediates? As an incubation of 15 min in the presence of ATP is required before intermediates I and II are first detected, it is likely that some essential, as yet uncharacterized, event must occur before the cleavage at the 5′ splice site. This could, for example, be either the formation of a nucleoprotein particle in which the precursor RNA would asume the conformation necessary for splicing, or an ATP-dependent activation of the branchpoint acceptor.

Is the branch acceptor nucleotide (usually an adenosine residue[8]) embedded in a highly specific sequence? This is unlikely in the case of eukaryotic introns, because, as shown by Wieringa *et al.*[10], deletions or substitutions that remove all but 15 nucleotides adjoining the 3′ splice site of the large β-globin intron do not impair splicing. In the case of the intron in yeast nuclear genes, however, an internal sequence (TACTAAC) is essential for splicing[11] and Pikielny *et al.*[12] have in fact mapped what may be a reverse transcription stop in this region. Ruskin *et al.* note that all β-globin introns contain a 'consensus sequence', of which the TACTAAC sequence is a subset, located in the region between 19 and 37 nucleotides upstream of the 3′ splice site. The consensus sequence is: Py-X-Py-T-Pu-A-Py (the underlined A represents the branchpoint in β-globin). The sequence in which the branchpoint identified by Padgett *et al.* for adenovirus is embedded conforms to this consensus sequence except that the fifth residue is a pyrimidine (Py) rather than a purine (Pu).

Since at least some of the intron deletions examined by Wieringa *et al.* do not contain a reasonable facsimile of the consensus sequence but are nonetheless efficiently spliced, it would seem that even if branch formation preferentially occurs within the consensus sequence, it may occur elsewhere if a consensus sequence is lacking; moreover, it remains to be proved that branch formation is essential for splicing.

Why does the 5′ end of the intron become joined to an internal nucleotide? It is striking that the introns of *Tetrahymena* ribosomal RNA and of yeast mitochondrial precursor mRNAs are released in circular form. Perhaps, as Ruskin *et al.* suggest, the initial cleavage may be reversible, and branch or circle formation are required to sequester the 5′ intron definitively, allowing the next reaction step to occur. Thus, although splicing in higher eukaryotes differs in many important respects from that in lower eukaryotes, they may have some mechanistic principles in common. ☐

Cystic fibrosis

In search of the gene

from Veronica van Heyningen

SADLY, the future of the 10th International Cystic Fibrosis Congress seems assured. The enigma of the primary gene defect in cystic fibrosis — the most common genetic disease in Caucasian populations (1 in 2,000 births) — has not yielded to the wide-ranging biochemical, physiological and molecular genetic approaches described at the 9th Congress*.

Cystic fibrosis is a disease of the exocrine glands which is inherited in an autosomal recessive fashion. It is characterized by the production of abnormally thick mucus in many organs, resulting typically in chronic obstructive lung disease; by pancreatic insufficiency often leading to malabsorption; and by abnormally high levels of sodium and chloride in sweat. This last feature is the basis for definitive diagnosis.

Despite the steadily improving prospects for afflicted individuals, the social implications of the disease are still serious, as was reflected in a study of parental attitudes in Californian cystic fibrosis families (M. Kaback *et al.*, University of California, Los Angeles). In 65 per cent of the 183 families studied, the affected child was the last born to the couple and more than a quarter of the couples resorted to surgical sterilization to avoid the possibility of having further offspring with the disease. Reliable prenatal diagnosis would clearly be welcome to such families.

Brock (*Lancet* **ii**, 941; 1983) and colleagues have found reduced levels of intestinal microvillar enzymes in amniotic fluid if an affected fetus is being carried in a pregnancy 'at risk' (previous cystic fibrosis child born to the parents). The reduced levels are thought to be secondary to the impaired passage of meconium in the cystic fibrosis fetus. Following the failure of an earlier prospective trial for reduced amniotic fluid protease activity (Nadler, H.L. & Walsh, M.M.J. *Pediatrics* **66**, 690; 1980) great caution is being exercised in confirming and extending these findings. Nonetheless, groups in Rotterdam (W.J. Kleijer *et al.*, Erasmus University), Paris

---

*9th International Cystic Fibrosis Congress, Brighton, 9-15 June 1984. The proceedings will be published this year (*Cystic Fibrosis: Horizons*; ed. Lawson, D., Wiley, Chichester; 1984).

(A. Boué *et al.*, Inserm U73) and Glasgow (D.A. Aitken *et al.*, University of Glasgow) are successfully applying microvillar enzyme estimations prospectively. Validation of this approach to prenatal diagnosis would be speeded up if definitive diagnosis of cystic fibrosis were possible in the fetuses declared abnormal and aborted on parental request. Confirmation of normal outcome in pregnancies carried to term is also difficult because there is considerable variability in severity and age of onset of overt disease, although neonatal sweat testing and immune-reactive trypsin measurement of newborns may help.

While there is every indication that prenatal diagnosis of this kind will help prevent the birth of a second affected child in families at risk, the assays are based on what is almost certainly a secondary phenomenon and the race to identify the basic gene defect is still on. Considerable excitement has been generated by recent work on isolated sweat glands (Quinton, P.M. *Nature* **301**, 421; 1983) and on nasal epithelium (M.R. Knowles, R.C. Boucher *et al.*, University of North Carolina). In both cases, there appears to be a defect in ion transport in affected individuals. Thus, raised potential differences across the apical membrane of epithelial cells suggest reduced chloride permeability, and this is accompanied by reduced responsiveness to β-adrenergic stimulus by isoproterenol. The possibility that the abnormal β-adrenergic responsiveness and secretion in cystic fibrosis results from a defective calcium-dependent regulatory protein was suggested by several workers, for a variety of tissues (R.M. Case, University of Manchester; G. Cabrini *et al.*, Centro Fibrosi Cistica, Verona; M. McPherson *et al.*, University of Cardiff). One of the few groups to study heterozygote as well as homozygote red cells observes a calcium transport defect in both (C.A. Seymour and J.A. Davis, University of Cambridge).

As long as the basic gene defect remains unidentified, the choice of tissue for study will be arbitrary and often made on the basis of availability. The ability to culture sweat gland epithelia (P.S. Pedersen, Rigshospitale, Copenhagen) may prove a useful stimulus in this field. Meanwhile, considerable effort is being made to set up reliable heterozygote detection using serum samples (Manson, J.C. & Brock, D.J.H. *Lancet* **i**, 330; 1980) as this would help in the search for the defective metabolic pathway and ultimately the primary mutant gene locus (A. Jamieson *et al.*, University of Glasgow; V. van Heyningen *et al.*, MRC Clinical and Population Cytogenetics Unit, Edinburgh; O. Guy-Crotte *et al.*, Inserm U31, Marseille). Various teams (R. Williamson *et al.*, St Mary's Hospital Medical School, London; K.W. Klinger, Case Western Reserve University, Cleveland; Lap-Chee Tsui *et al.*, Hospital for Sick Children, Toronto; and R.H. Schwartz *et al.*, University of Rochester) are setting up DNA banks or permanent cell lines from cystic fibrosis families with two or more affected children.

The only available method of searching for the cystic fibrosis gene is linkage analysis by exclusion mapping using polymorphic DNA probes that have been mapped to a known chromosome region. In this way, using samples only from affected individuals and obligate heterozygotes, a number of chromosome regions have been found not to be linked to cystic fibrosis. Just before the congress took place, there was excitement about the possibility of assigning the cystic fibrosis gene to the tip of the long arm of chromosome 13 on the basis of an informative family with a segregating translocation (Edwards J.H., Jonasson J.A. & Black N.L. *Lancet* **i**, 1020; 1984), but this now seems unlikely. Nonetheless, an air of optimism pervaded the conference because the introduction of new methods such as electrophysiology and gene cloning brings some promise of breakthrough. □

Cellulose synthesis

Another brick in the wall

from Keith Roberts

IT is estimated that almost 2 × 10^{12} tonnes of carbon are wrapped up in organic molecules on the landmasses of this planet. The most abundant of these molecules, accounting for just over one-third of the dry weight of plants, is cellulose. Indeed, there is so much of it that cellulose forms the major buffer for the levels of carbon dioxide in the atmosphere. For a macromolecule of such abundance and economic importance (wood, paper, cotton), it is really rather astonishing that we still do not know in detail how it is made (Colvin, J.R. in *The Biochemistry of Plants*, ed. Preiss, J., 543, Academic, New York; 1980). What is clear is that higher plants have a remarkably complex and delicate machinery for synthesizing the basic building blocks of cellulose, the glucan chains, and for ordering their crystallization and orientation in the cell wall. The difficulty in trying to dissect the complexity of this machinery has been in obtaining an *in vitro* system that will make identifiable cellulose (Delmer, D.P. *Adv. Carbohyd. Chem. Biochem.* **41**, 105; 1983). Until now, despite many false alarms in the literature, no one has managed to do this. However, a report in this issue of *Nature* at last holds out some promise by describing the production of cellulose *in vitro* using a membrane preparation from a higher plant.

Cellulose is a (1→4)-β-D-glucan, consisting of many long parallel polysaccharide chains held together by inter- and intramolecular hydrogen bonds to form microfibrils, typically 10–40 nm in diameter. The microfibrils are extremely insoluble and form the high-tensile-strength skeletal framework of the plant cell wall (see the figure). The consensus of opinion is that the enzyme or enzyme complex that produces cellulose is an integral protein(s) of the plasma membrane. Most efforts to achieve cellulose synthesis *in vitro* have therefore started with isolated membrane preparations, usually either from rapidly elongating tissue such as the hypocotyl, or from cells laying down large amounts of cellulose, such as those that make cotton fibres.

Why has none of the previous attempts to mimic *in vivo* cellulose synthesis with *in vitro* membrane preparations been completely successful? The answer, at least in part, lies in the complexity of the process itself and in the structural constraints on the system which have to be preserved *in vitro*. Initially, even the precursors that the plant uses to make cellulose were the subject of dispute, with opinion slowly shifting from GDP-glucose to UDP-glucose. Intact cells take up and use exogenous UDP-glucose very poorly, the cellulose synthase complex accepting UDP-glucose only on its cytoplasmic face. Somewhow UDP-glucose has to gain access to the inner face of the membrane and, in general, cell breakage leads to inactivation of the synthetic complex. There has also been disagreement about the role, if any, of various intermediates. Both lipid-linked intermediates and glycopro-

The complex texture of cellulose microfibrils *in vivo* is revealed in this metal-shadowed specimen of an extracted primary cell wall. The specimen comes from a root hair cell of an onion. (Micrograph by B. Wells.)

tein intermediates have been invoked at various times, but neither has been conclusively shown to be involved. Uncertainty also prevails over the requirements for Ca^{2+} and Mg^{2+}, GTP and various other soluble cofactors. The biggest stumbling block and the greatest puzzle have been that *in vitro* systems used so far have invariably been able to incorporate glucose into high-molecular-weight material, but the product always seems predominantly to be $(1\rightarrow3)$-β-D-glucan (callose) and not $(1\rightarrow4)$-β-D-glucan (cellulose). The reasons for this are unclear but it was suggested at two recent meetings* that cell damage or wounding stimulates callose production at the expense of cellulose, possibly because of altered Ca^{2+} access to each side of the membrane. It was even suggested by D. Delmer (ARCO, California) at the Fribourg meeting, and by D.H. Northcote (University of Cambridge) at the Glasgow meeting, that the same enzyme complex, regulated by Ca^{2+}, may be involved in the synthesis of both polymers.

Clearly, the complexity of the synthetic system is great and a model system is required. In this case, as in so many branches of cell biology, the model system is a bacterium, *Acetobacter xylinum*, which produces a cellulosic pellicle in liquid culture. Two years ago, a collaboration between D. Delmer and M. Benziman's group in Israel resulted in high rates of *in vitro* synthesis of cellulose using a stabilized membrane fraction from this bacterium (Aloni Y. *et al. Proc. natn. Acad. Sci. U.S.A.* **79**, 6448; 1982). Success appeared to depend crucially on the presence of polyethylene glycol 4000 (PEG) which stabilizes sealed membrane vesicles and aggregates proteins.

Now, in another attempt with higher plants, T. Callaghan, working with Benziman, has elegantly applied the same basic methodology to membrane fractions from mung bean hypocotyls, apparently with remarkable success (see page 165 of this issue). Using a PEG-stabilized preparation, they are able to achieve rates of cellulose synthesis that approach those found *in vivo*. Notably, no detectable $(1\rightarrow3)$-β-D-glucan is formed, Ca^{2+} and Mg^{2+} are both essential, no intermediates are formed and cellobiose and another low-molecular-weight soluble factor increase the rate of synthesis. Although the crucial final X-ray demonstration of authentic cellulose has not been done, the notoriously difficult chemical characterization of the product appears convincing.

At present it is hard to identify the reasons for this success where previous attempts had failed. One reason put forward is that because the system is very complex, it makes sense to tamper with it as little as possible; thus high-speed spins and any attempt to 'clean up' the membrane fraction have been avoided. This, together with the use of stabilizing PEG and the correct choice of cofactors, may have tipped the scales in Callaghan's and Benziman's favour. It will be interesting to see whether the new methodology is repeatable and whether it can be used with other plant material.

If it does prove to be a viable system for the *in vitro* synthesis of cellulose and not, for example, a way simply of making the glucan backbone of hemicellulose molecules, the door is opened for exploring a whole range of extremely important issues in higher-plant cell biology. As well as being able to investigate the factors that control the width and length of cellulose microfibrils, the separation or otherwise of the synthesis and crystallization processes and the true relationship between callose and cellulose synthesis, it should also be possible to attack one particularly thorny critical problem. For many years it has been suggested that particular plasma membrane complexes seen in the electron microscope correspond to cellulose synthase assemblies (Giddings, T.H. *et al. J Cell Biol.* **84**, 327; 1980). An extension of this idea, which still has no strong experimental backing, is that the complexes move through the plane of the membrane, spinning out microfibrils into the extracellular matrix as they go. Elements of the plant cytoskeleton, the cortical microtubule array, are thought to define membrane channels in which the complexes are free to move, and may therefore control the orientation of cell-wall microfibril deposition. As wall texture is fundamental to organized cell expansion, this phenomenon is at the heart of many fundamental problems of plant cell growth and differentiation. It looks as though at least one possible avenue for attacking them has been opened up. □

Sex chromosome evolution

Sharing outside of pairing

from R.P. Erickson and P.N. Goodfellow

THE human X and Y chromosomes are very different in appearance and genetic content and yet are believed to be derived from an ancestral pair of chromosomes differing only at a single sex-determining locus. Several models for the evolution of mammalian sex chromosomes have been proposed to explain sex chromosomal differentiation but experimental evidence to decide between the models has been lacking. Analysis of cloned DNA sequences from the human sex chromosomes, particularly the Y chromosome, should eventually solve the problem of how the X and Y chromosome have evolved and should provide clues to the mechanism of sex determination. This approach has been used by two groups who report their results in *Nature* this week and next.

Genes determining testicular and ovarian development predate fixed chromosomal sex determination in evolution. One can imagine that two nonhomologous chromosomes separately accumulated genes for sexual differentiation, genes for male development on an ancestral Y and genes for female development on a nonhomologous ancestral X. However, evolution of sex chromosomes from a homologous pair appears frequently in vertebrate evolution and is the usually accepted mechanism.

Given a pair of homologues, one with male-determining genes, two theories have been proposed to explain the evolution of sex chromosome differentiation. The classic model of sex chromosome evolution from homologues places cross-over suppression between the ancestral pair as the primary event with a slow accumulation of differences by mutation[1]. Later, X-chromosome inactivation occurs to maintain the gene dosage for genes now found only on the X chromosome. An alternative theory puts chromosomal inactivation of the non-sex-determining portion of the sex chromosomes first[2], solving the male/female sex-chromosomal dosage problem at the start. The selective force hypothesized in the classic model is the need to keep a block of sex differentiation genes intact. The selective force in the alternative model is the still obscure advantage of chromosomal sex determination. Both models assume continued crossing-over between homologous Xs and, thus, explain the observation that while the X chromosome has retained many structural genes apparently unconnected with the process of sexual differentiation, the much smaller Y chromosome seems to have lost all but a small number of genes directly concerned with sex determination and male gametogenesis.

There are two major limitations on sex chromosome differentiation. First, sex chromosome pairing must occur at meiosis for normal chromosomal disjunction. Chromosomal pairing is thought to depend on sequence similarity and this implies that the X and Y chromosomes should show sequence homology in the X–Y pairing region. Light microscopic studies of human meiosis have shown that the pairing region includes the terminal third of the X-chromosome short arm and most of the Y-chromosome short arm[3]. Second, the sex-determining region must not be disrupted by recombination with the X chromosome. The consequences of transfer of sex-determining genes from the Y to the X chromosome can be seen in the generation of sterile XX males by the transfer of the *Sxr* fragment in the mouse[4,5]. A similar event has been demonstrated in some XX human males who have inherited Y-derived sequences[6]. Correlation of clinical and cytogenetic findings in patients with rearranged Y chromosomes has localized the sex-determining region to around the centromere of the Y chromosome, well outside the pairing region[7]. Thus, it would be predicted that homologous sequences shared by the X and Y chromosomes would be restricted to the X–Y pairing region. This prediction is compatible with the localizations of the only expressed gene known to be homologous between the X and Y chromosomes[8]. Studies with cloned sequences derived from the Y chromosome, however, have found considerable sequence homology between the X and Y chromosomes outside the pairing region.

Early studies of human Y-chromosomal DNA emphasized the large amount of relatively Y-specific repeat elements (reviewed in ref. 9). The cloning of Y-chromosomal DNA in cosmid vectors, however, has led to the isolation of unique-sequence sub-clones[10-13], many, but not all, of which also hybridize to the X chromosome. Furthermore, several clones from X-chromosome libraries have been found to hybridize with the Y[13,14]. Many of the X and Y shared sequences have been mapped to the short arm of the Y and the long arm of the X[11-15]: the homology does not fit the pairing seen at meiosis. The simple prediction is also not supported by the two new studies reported in *Nature*. One of the first sequences shown to be shared by the X and Y chromosomes was isolated as a random fragment from a total human genomic library[16]. On page 119 of this issue, Page *et al.* show that the homology region extends for at least 36 kilobases (kb) and maps to the short arm of the Y chromosome and the long arm of the X chromosome (Xq13–Xq21), well outside the X–Y pairing region[17]. Careful restriction mapping suggests that the X and Y sequences are at least 98 per cent homologous. An even greater degree of homology has been found by Cooke and Rappold (next week's *Nature*) for a sequence first isolated from a genomic library made from flow-sorted Y chromosomes[18]. Direct sequencing of the X- and Y-derived clones shows no differences in over 1 kb. This DNA segment too maps to the long arm of the X chromosome, but it maps to the heterochromatic region of the Y chromosome, well outside the pairing region.

Page *et al.* have gone on to study the origin of their homologous sequence by investigating DNA from male and female primates[17]. They find that in chimpanzees, gorilla and orang-utan, the sequence is found only on the X chromosome. Genomic mobility may be a feature of many Y-chromosome sequences and has been documented previously both for the Y-specific repeats and unique sequences. The 3.4-kb repeat, which may constitute as much as 40 per cent of the human Y chromosome, may have an autosomal origin[9]. In this case, transfer of a few repeats followed by rapid expansion mediated by unequal crossing-over or gene duplication (or both) could be envisaged. For other sequences found on the X, Y and autosomes, such as actin[19] and arginsuccinase[20] pseudogenes, a mRNA origin is likely. It is not clear that such mechanisms can explain the transfer of the 36 kb segment described by Page *et al.*, nor the other X–Y homologous sequences reported to map outside the pairing region. At least one of these other sequences also spans greater than 20 kb (ref. 13). The high degree of sequence conservation suggests that the X–Y exchange must have occurred relatively recently, perhaps as the result of double recombination events facilitated by normal X–Y pairing or as a function of an ancient pre-existing homology. It is also possible that a new mechanism analogous to gene conversion but occurring on a larger scale may be operating. ☐

Embryonic development

Cell communication in early embryos

from Jonathan Slack

'LOW-RESISTANCE' junctions between cells in embryos and many adult tissues were discovered in the 1960s by their ability to pass electric current[1]. Later it became clear that they were the same as the 'gap junctions' seen under the electron microscope as open channels connecting adjacent cells, and that they were capable of passing most substances of molecular weight less than about 1,000 (ref. 2). A popular view has been that gap junctions transmit the inductive signals that control regional specification in the early embryo. But although the junctions have been mapped in embryos of various types[3-6], functional evidence for this interpretation has so far been lacking because there has been no method of blocking the junctions *in vivo* without unacceptable side effects. Now, in this week's *Nature*, Warner, Guthrie and Gilula describe a means of doing just this by injection of antibody against gap junction protein into early *Xenopus* embryos[7]. The authors are very cautious in their interpretation; nonetheless, the experiments provide the first direct evidence that gap junctions indeed have a role in early embryonic development.

Before these experiments could be done, it was necessary to know the normal disposition of junctions in the *Xenopus* embryo. Previous electrophysiological studies had shown that cells of the early embryo were coupled[3], but the work was done without reference to the positions of the cells studied. In the paper by Guthrie in this week's *Nature*[8], each of the blastomeres in the animal hemisphere of the 32-cell stage has been injected with the fluorescent dye Lucifer Yellow and it is shown that dye transfer is much more frequent between the cells on the dorsal side than between those on the ventral side.

Warner *et al.* therefore selected a dorsal blastomere of the 8-cell stage for injection of antibody to gap junction protein, and then studied dye-coupling at the 32-cell stage between the progeny of the injected cell[7]. They find that the frequency of dye-coupling is substantially less than in untreated embryos and in most cases cells which fail to transfer dye are also uncoupled electrically. By contrast, injection with preimmune serum or an unrelated antibody is without effect.

At later developmental stages the injected embryos show substantial morphological defects in the region derived from the injected blastomere: the brain and eyes being absent or reduced. These defects do not arise from cell death, which would be very obvious in an embryo type which develops without increase in size. Rather, they appear to be due to a failure of neural induction since in normal development the neural tube is induced from dorsal ectoderm by the action of the underlying mesoderm. This might be because the tissue movements during gastrulation have been disturbed so that the disposition of ectoderm and mesoderm is abnormal; alternatively, it might be the result of a direct blockage of the transmission of the inducing signal. It should be possible to distinguish between these possibilities by co-injecting a lineage label[9] with the antibody to enable movements of the affected cells to be followed.

A direct role for gap junctions as channels for the neural inducing signal is perhaps unlikely in view of the fact that at least the early steps of neural induction can occur in the absence of any cell contact[10], implying that the active substances can diffuse across extracellular spaces. Nonetheless, neural induction shows considerable regional specificity, particular regions of the archenteron roof inducing corresponding regions of the nervous system[11], so the whole process is probably more complex than the transmission of a single substance. Clearly, gap junctions are involved in some way but more work is needed on the unfashionable problem of the biochemistry of inducing factors before we can make a final assessment. ☐

Geology

Geological problems of north-east Africa

from Robert Bowen

EARTH satellites are helping to uncover valuable data about the sub-surface topography of arid regions such as the western Sahara and the Mojave deserts. So much was clear from an international meeting* on the geography of north-east Africa earlier this year, in advance of the launch on the US NASA shuttle later this year of the second shuttle imaging radar (SIR-B) designed by the Jet Propulsion Laboratory (Pasadena).

The first SIR experiment in 1982 led to the still remarkable reports of 'radar river' deposits, described by J. McCauley and C. Breed for themselves and G. Schaber (U S G S, Flagstaff, Arizona). They occur as buried channels in the Western Desert of Egypt, where broad valleys and younger inset channels have been identified using radar responses from surface and subsurface materials including caliche horizons in fluviatile sediments. Such features have promoted a new understanding of the regional role of running water in shaping the hyperarid core of the Sahara, before the onset of the periodic Quaternary aridity, and have made it possible to understand fluviatile environments including some containing 'Acheulian' artefacts of presumed late Pleistocene age, which have been located incidentally to stratigraphic investigations in backhoe trenches.

In an extension of the radar technology (R. Blom, JPL), igneous dykes beneath as much as 2 m of alluvium were detected in the Mojave Desert by the Seasat L-band (23.5 cm) synthetic aperture radar in 1978, when soil moisture probably fell below the 1 per cent critical microwave absorption level. Blom pointed out that the Mojave is a 'swamp' compared to the hyperarid eastern Sahara, and can be examined only when moisture content declines sufficiently. Other factors such as the roughness and the dihedral configuration of the dykes were significant because they helped in the generation of strong radar echoes. Clearly, conditions suitable for the detection of subsurface features may exist intermittently in places previously considered unsuitable, although the definitive interpretation of radar tracking image data may need subsequent field work.

There was some controversy at this meeting over Egyptian and Sudanese stratigraphy, a supracratonic arenaceous sequence extending through most of the Phanerozoic. Until recently, access has been difficult while the marginal interest of the petroleum companies has reduced further the number of geologists actively working in these countries. However, in the last couple of decades, progress has been made by attempts to clarify the so-called Nubian sandstone (B. Issawi, Egyptian Geological Survey; E. Klitzsch, Technical University of Berlin).

The disagreement derives from correlation of clastic beds, especially those of supposed Palaeozoic age. The stratigraphic position of fluvio-glacial deposits occurring both in Egypt and in Sudan, originally given as Ordovician by Klitzsch, has been traced laterally from Libya across to Saudi Arabia by U. Jux (University of Cologne). The situation is now unsatisfactory because Klitzsch (*J. Afr. Earth Sci.* **1**, no.1, 17; 1983) re-assigned the deposits to the Permo-Carboniferous ('karroo-type'), which implies an equivalence to the Dwyka glaciation of southern and south-central Africa and of course a totally new concept of Gondwana and its biotas. The pre-Carboniferous Palaeozoic column in southern Egypt is devoid of index fossils, so that the stratigraphy is to a large extent based on ichnofossils such as Cruziana and Bifungites, the identity and reliability of which were disputed.

Proper correlation is presently impossible in this vast terrain which was previously considered to embody a 'pancake'-type geology but, because of epeirogenic movements of the Uweinat-Aswan geanticlinal arch, is now known to have been marked by cyclic transgression and regression events involving deposition and erosion (D. Bhattacharryya, Washington University; B. Issawi). Klitzsch takes the view that there was a change in the fluviatile discharge direction in Egypt and Sudan, reversing an earlier north–south flow, but more data are needed to resolve this question.

Obtaining more detailed geological information is even more necessary in Sudan where, as R. Stern (University of Texas, Dallas) pointed out, sampling is hardly richer than on the Moon. He presented some interesting chronometric results supporting a model for the tectonic evolution of the Sudanese basement in the late Proterozoic.

Another very controversial subject is that of the aquifer systems of Libya and Egypt, where the occurrence of recharge and groundwater flow are in dispute. M.U. Ahmad (University of Ohio) presented a steady-state groundwater flow model for the southern Libyan basins which has been applied to test the existence of recharge through the past five thousand years. Ahmad believes this to have occurred, in which case the water problems of the region can be solved. The flow rate from Libya to Egypt is given as almost 4 million m^3 daily, a figure with which Issawi strongly disagrees.

The meeting ended with a lively discussion of the Libyan glass enigma. J. Underwood Jr (Kansas State University) and R. Giegengack (University of Pennsylvania) cited various unacceptable explanations and an unpublished paper by U. Jux which deals with the differing origins of Libyan astroblemes and the glass. Underwood, Giegengack and Jux agree on a terrestrial origin, and the only viable model appears to be that suggested by Jux in 1983 — a diagenetic silcrete-type mechanism of formation under early Neogene semiarid conditions resulting from reaction between superficial waters containing carbon dioxide and alkaline highly-siliceous subterranean and groundwaters. ☐

Breaking a Yang–Mills symmetry at very high energy could lead to macroscopic structures in the vacuum called 'strings', which may be the cause of galaxy formation and clustering. Dissipative gravitational interactions of string loops can produce unusual astrophysical side effects. Such scenarios generally predict a stochastic background of gravitational radiation which should be observable using the millisecond pulsar 1937+21. Gravitational radiation recoil accelerates loops, but dynamical friction on ordinary matter tends to slow them down so they may be able to accrete matter. Internal oscillations of loops produce a time-varying shear perturbation which may lead to an observable heating of stellar or gaseous systems in their immediate neighbourhood.

THE general acceptance of Yang–Mills theories of fundamental interactions, and the associated idea of their intrinsic symmetries being 'broken' by an asymmetric vacuum, have led physicists to endow the vacuum with an ever-increasing number of degrees of freedom and intrinsic structural properties. The vacuum, as now envisaged, can sustain long-lived and even macroscopic structures. A vacuum in three-dimensional space can have three types of topologically stable 'defects'—monopoles, strings, and domain walls, corresponding to zero-, one-, and two-dimensional surfaces in which the vacuum is 'trapped' in its high-energy symmetric state[1]. Astrophysical effects of magnetic monopoles have attracted much attention recently because of their possible revolutionary implications for a 'grand unified' Yang–Mills theory and for cosmological models[2]. The possibility of relic cosmic strings has also been studied, primarily with a view towards using them to produce the density fluctuations leading to galaxy and galaxy–cluster formation[3–5].

Here, we study various other astrophysical consequences of such string scenarios. One of the most serious observational constraints on strings (or conversely, their most promising distinctive observational signature) is the background of gravitational radiation they would produce[6], which is now detectable because of the precision of the millisecond pulsar. Within a few years, measurements will probably be sensitive enough to exclude any scenario which suggests that strings produce galaxy clustering using only their direct gravitational effects.

We also study some other unusual interrelated consequences of the string picture, including: (1) recoil reaction of gravitational radiation on oscillating loops; (2) damping of the translational energy of such loops by dynamical friction on ordinary matter; (3) accretion of ordinary matter bound to a loop and the motion of a loop within its potential well; and (4) the dissipative coupling of the internal energy of loops to ordinary matter. In some situations, loop oscillations can noticeably affect bound stellar or gaseous systems, although as far as the loops are concerned there are generally no comparable energy-loss mechanisms to the gravitational radiation.

Finally, we consider the possibility of using strings as 'seeds' in an alternative theory of galaxy formation, in which they are required only to produce some pregalactic energy sources instead of the whole of the observed clustering energy. This allows the use of much lighter strings and hence avoids, for the time being at least, the gravitational-wave constraint. The minimum value of the string mass expected to have significant astrophysical effects has some interest because string production is predicted in association with a Peccei–Quinn symmetry breaking, generally thought to occur at well below the grand unification scale ($\simeq 10^{12}$ GeV to close the Universe with axions)[7].

General properties of strings

Strings are topologically-stable structures which may appear in the vacuum as a result of domains formed during the breaking of a Yang–Mills symmetry, if the topology of the manifold of degenerate vacua in the broken phase is appropriate. They have a mass per unit length $\mu \equiv \varepsilon / G$, where $\varepsilon \simeq (\langle\varphi\rangle / m_p)^2$ is the dimensionless amplitude of their gravitational potential, m_p is the Planck mass, and the vacuum expectation value of the Higgs field is $\langle\varphi\rangle$. Because of their enormous tension ε / G the network of strings formed in the transition, which may be thought of as a superposition of random walks, strives to reduce its length by ironing out small scale wrinkles at close to the speed of light and allowing strings, when they cross, to intercommute or exchange partners. Strings are forbidden to have ends (at least in the simplest models) so they must either be in closed 'loops' or in infinite 'open' strings.

A closed loop whose radius matches the current horizon size t_i has a good chance of not intercommuting further with the rest of the network. The behaviour of isolated closed loops is still open to question. They tend to undergo oscillations in which the transverse inertia acts as a 'weight' and the restoring force is provided by longitudinal tension. What is not known is how frequently an initial loop configuration chosen 'at random' (from the network of self-avoiding random walks) will cross itself and bifurcate into smaller loops, and how frequently it will oscillate indefinitely as a stable object. If the latter case is not very unlikely, the network produces debris of stable oscillating loops smaller than the current horizon which are effectively decoupled from each other and from the rest of the network. These loops eventually decay by gravitational radiation at a time $t_{dec} \simeq \varepsilon^{-1} t_i$. At a time t loops which are larger than $R_{dec} \simeq \varepsilon t$ (the ones currently decaying), and which separated out at $\simeq t_i$ have a mean separation (in the long-lived case) of the order of $R_{sep}(t) \simeq (a(t)/a(t_i))t_i$, where a is the Friedmann scale factor. During the matter-dominated era (for $t > t_{eq}$), loops in each logarithmic interval of loop size $R_l \geqslant t_{eq}$ contribute a fraction $\sim\varepsilon$ of the mean cosmological density; for $R_l < t_{eq}$, the fraction increases as $R_l^{-1/2}$ (because of the change in the expansion law when these loops entered the horizon), down to R_{dec}, below which it falls off like R.

Although many properties of loops can be estimated only in an order-of-magnitude sense, it is sometimes useful to be reasonably definite in normalization of certain quantities.

(1) We assume that loops form when their radius is equal to H^{-1} (the current Hubble time), and that, on average, one half of such a loop appears in a typical spherical volume of radius cH^{-1}. This leads to an estimate of the mass–density perturbation

by the loops at horizon crossing $(\delta\rho/\rho)_{\mathrm{hc}} = 2\pi\varepsilon$.

(2) The value of ε required to produce galaxy clustering by gravitational interaction alone depends on the composition of the dark matter, because of the usual damping processes which can take place at high redshift. However, a useful estimate of a lower limit for ε can be obtained by assuming a matter-dominated universe of cold particles. Simple scaling derived from the linear-growth model for the perturbations $(\delta\rho/\rho)_{\mathrm{hc}}$ after they enter the horizon gives

$$(\delta\rho/\rho)_{\mathrm{hc}} = (r_0/ct_0)^2 \qquad (1)$$

where r_0 is the radius for which randomly sampled spherical volumes have unit variance in density at the present epoch, $\langle\delta\rho^2\rangle_{r=r_0} \equiv \langle\rho^2\rangle$. Estimates of the galaxy correlation function show that $r_0 \simeq 10\ \mathrm{Mpc}\ h_{100}^{-1}$ where $h_{100} = H_0/100\ \mathrm{km\ s^{-1}\ Mpc^{-1}}$ (for a more detailed discussion see ref. 9), so

$$2\pi\varepsilon \gtrsim 10^{-5} r_{10}^2 \qquad (2)$$

if strings are to produce galaxy clustering by gravity alone. (This estimate applies independently of the probability of loop formation because it only relies on linear growth after t_{hc}.) In what follows we use a fiducial value $\varepsilon_{-6} \equiv \varepsilon/10^{-6} \gtrsim 1$.

(3) Oscillating loops, in their gravitational interaction with normal matter, behave like a mass $M_1 \cong 2\pi\mu R_1$ spread out over the volume covered by the oscillations (in a sense to be described below). It is useful to associate loops with a virial velocity $v_{\mathrm{vir}} \simeq \varepsilon^{1/2}$, a virial time $t_{\mathrm{vir}} \simeq \varepsilon^{-1/2} R_1$ and a virial temperature $T_{\mathrm{vir}} \simeq \varepsilon m_{\mathrm{pr}}$ where m_{pr} is the proton mass. The circular orbital velocity of a particle around a circular loop at the loop radius is

$$v_{\mathrm{vir}} = \sqrt{2GM_1/R_1} \cong 1{,}000\,\varepsilon_{-6}^{1/2}\ \mathrm{km\ s^{-1}} \qquad (3)$$

(4) Turok[5] has found exact solutions for which the simple order-of-magnitude estimate for the gravitational-wave decay half-life, τ_{dec}, of loops is remarkably accurate:

$$\tau_{\mathrm{dec}} \simeq \varepsilon^{-1} R_1 \qquad (4)$$

to within a factor of two for various modes.

Since loops have a constant $GM/R \simeq \varepsilon$, smaller loops have a higher effective local density contrast $M_1/(\rho_{\mathrm{m}} R_1^3) \propto M_1^{-2}$ where ρ_{m} is the matter density. Loops whose mean density matches the background have a mass $\simeq \varepsilon^{3/2} M_{\mathrm{H}}$, where $M_{\mathrm{H}} = 4\pi\rho_{\mathrm{m}} t^3/3 = t/2G \simeq 10^{23} M_\odot h_{100}^{-1}\Omega$ is the current horizon mass Ω is the cosmic density parameter); loops which are currently decaying have a density contrast $\simeq \varepsilon^{-1}$, and are very much denser than background matter in their vicinity. Their mass is $M_{\mathrm{dec}} \sim 2\pi\varepsilon^2 M_{\mathrm{H}} \simeq 6\times10^{11}\varepsilon_{-6}^2 \Omega h_{100}^{-1} M_\odot$, their radius is $R_{\mathrm{dec}} \simeq 3h_{100}^{-1}\varepsilon_{-6}$ kpc, and their mean separation is $\simeq \varepsilon^{1/3} t \simeq 30 h_{100}^{-1}\varepsilon_{-6}^{1/3}$ Mpc (loops of this size are the most numerous). If these loops are present in the Universe today, the discussion below indicates that some, at least, should be found in clusters of galaxies, and we expect roughly one loop per rich cluster.

Gravitational wave background

Vilenkin[6] has sketched out the gravitational wave background expected in the loop scenario. Here we consider several regimes and compare the predictions with current limits from the millisecond pulsar.

Let us suppose that newly-formed loops fall with probability W into the set of infinite-non-self-intersecting trajectories[8]. A fraction W of horizon-sized loops form a long-lived stable population as described above, and all of their rest mass is released eventually as gravitational radiation at z_{dec}. Let the differential energy spectrum of gravitational waves of frequency ω be $\rho_{\mathrm{g}}(\omega)$; define a logarithmic spectrum Ω_{g} by

$$\rho_{\mathrm{g}}(\omega)\,\mathrm{d}\omega \equiv \Omega_{\mathrm{g}}(\omega)(d\omega/\omega)\rho_{\mathrm{c}} \qquad (5)$$

where ρ_{c} is the critical density. Gravitational waves redshift in exactly the same way as electromagnetic ones, so loops which formed and decayed during the radiation-dominated era produce a background with

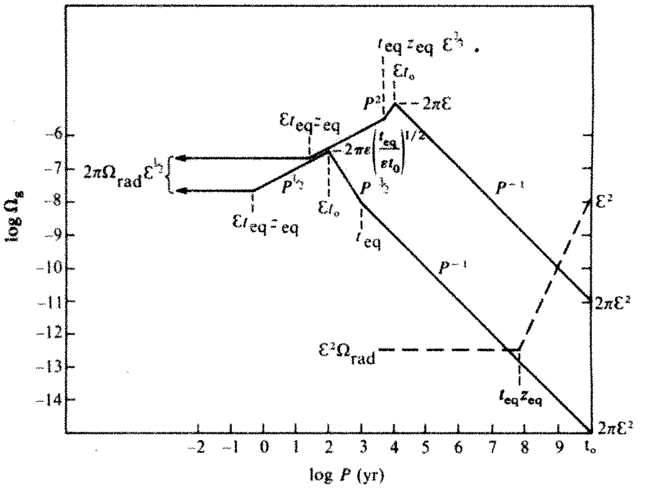

Fig. 1 Spectrum of stochastic gravitational radiation background produced by population of oscillating loops. Logarithmic energy density is plotted against period for two cases, $\varepsilon = 10^{-8}$ and 10^{-6}. Inflection points between different power-laws correspond to waves emitted by loops which decayed or entered the horizon at t_{eq}, and loops which are now decaying. The upper curve corresponds to the case of strings important for galaxy clustering, and can be tested against data at $P \sim 1$ yr. The dashed line represents the background produced by primordial tensor perturbations in the metric.

$$\Omega_{\mathrm{g}} \cong W\Omega_{\mathrm{rad}}\left(\frac{\delta\rho}{\rho}\right)_{\mathrm{hc}}\left(\frac{z_{\mathrm{i}}}{z_{\mathrm{dec}}}\right) \simeq 2\pi W\Omega_{\mathrm{rad}}\varepsilon^{1/2} \simeq 2\times10^{-7} W\varepsilon_{-6}^{1/2} h_{100}^{-2} \qquad (6)$$

where z_{i} is the redshift of loop formation, the z factor is the amount $\approx \varepsilon^{1/2}$ by which the radiation redshifted between z_{i} and z_{dec}, and we have used $\Omega_{\mathrm{rad}} \simeq 10^{-4.5} h_{100}^{-2}$ and $(\delta\rho/\rho)_{\mathrm{hc}} \simeq 2\pi\varepsilon$. This flat specimen extends down to waves emitted by loops which formed near the time of the phase transition itself, at temperature $\simeq \varepsilon^{1/2} m_{\mathrm{p}}$. This corresponds to a present-day period $P_{\min} \simeq 10^{-11.5} N^{-1/2}$ s (independent of ε), where N is the number of particle degrees of freedom. The shape of the spectrum at longer wavelengths depends on whether the loops currently decaying formed before or after t_{eq} (whether $t_{\mathrm{eq}} < \varepsilon t_0$ or $t_{\mathrm{eq}} > \varepsilon t_0$, the latter case being more likely); these spectra are summarized in Fig. 1, which includes the case considered by Vilenkin. The waves observable with the millisecond pulsar, with periods P of the order of 1 yr, were emitted at a redshift

$$z_{\mathrm{dec}} \simeq 2\times10^6 \varepsilon_{-6} P_{\mathrm{y}}^{-1} N^{-1/6} \qquad (7)$$

and originally had a period

$$t_{\mathrm{i}} \simeq P_{\mathrm{y}}^2 \varepsilon_{-6}^{-1} N^{1/3} \times 10\ \mathrm{s} \qquad (8)$$

Therefore, the waves in this scenario are relics of the early stages of the expansion, emitted by loops which formed shortly after nucleosynthesis.

Note, however, that the strings give a gravitational wave background very different from a primordial spectrum of curvature fluctuations (produced at the end of inflation[10], say); in this case, if scalar and tensor modes have comparable metric perturbations $|h_{\mu\nu}|$, the gravitational wave density $\Omega_{\mathrm{g}} \simeq h^2(P/t_0)^{-2}$ is of the order of $(\delta\rho/\rho)_{\mathrm{hc}}^2$. Another semi-classical source of perturbations might be the Starobinsky[11,12] effect, which produces gravitational waves (without scalar fluctuations) which enter the horizon with $\Omega_{\mathrm{g}} \simeq (\delta\rho/\rho)_{\mathrm{hc}}^2 \simeq (H_{\mathrm{inf}}/m_{\mathrm{p}})^2$, where H_{inf} is the Hubble constant during inflation. The spectrum from these effects is also plotted in Fig. 1. The short-wave cutoff in this case is $\simeq (H_{\mathrm{inf}}/m_{\mathrm{p}})^{-1/2} P_{\min}$. One can set constraints on H_{inf} using microwave anisotropy measurements (because in this case the waves are already present when the relevant scales enter the horizon), and the millisecond pulsar can only set more severe constraints if its Ω_g sensitivity goes below $\Omega_{rad}(\delta T/T)^2$ where $\delta T/T$ is the sensitivity of anisotropy measurements. In these scenarios, the microwave background isotropy is likely to remain a more sensitive constraint.

If W is sufficiently less than 1 there will also be a contribution from recently-formed loops. Let us consider a scenario in which an oscillating loop bifurcates frequently, leading to a 'cascade' of loop divisions to successively smaller scales. A loop of mass M will on average bifurcate $\simeq \log_2 W$ times until there are $\sim W^{-1}$ daughters and there is a good chance that one of its progeny, of total energy $\approx MW$, is oscillating in a mode where it is stable. Each successive division of the remaining progeny will leave behind some stable loops, which contain a total mass $\simeq MW$ in each logarithmic 'generation'. In general, each division converts some fraction $1-f$ of the loop length into translational motion of the succeeding generation, so that after n divisions loops are moving with relativistic γ-factors $\sim f^{-n}$. The stable loops radiate their rest mass into gravitational waves, as usual, but their radiation, even if emitted isotropically in their rest frame, is now beamed into a solid angle γ^{-2} and blueshifted (within the beam) in frequency by a factor γ. The resulting background has a spectrum

$$\Omega_g \simeq \min\left[\varepsilon^2 W(P/t_0)^{1/\log_2(f^2/2)}, \varepsilon W\right]$$

which at sufficiently high frequencies could, in principle, be larger than the 'primordial' contribution of equation (6). However, in general, this background is not stochastic; only a small fraction of observers lie within the beam of a radiating loop. In principle, Earth-based gravitational wave antennas might pick up occasional events from loop events of this type, coming from redshifts $\leqslant 10^6$, if W is moderately small. There is, however, only a small range of W in which these events could occur where one would not encounter a more serious constraint from the γ-ray background, as we now explain.

After $n \sim W^{-1}$ bifurcations, the entire rest mass of the original loop is locked up in non-self-intersecting loops. For $W \leqslant -\log(f/2)/\log(\langle\varphi\rangle t_0)$, most of the rest mass of the original loop remains when the daughter loops become so small that non-gravitational interactions become important at $R_l \simeq \langle\varphi\rangle^{-1}$, at which point the energy is presumably radiated in a complicated mixture of coherent vacuum phase waves and high-energy particles. Thus for very small W, the best constraint is likely to come from the γ-ray background produced by the smallest loops in the cascade. Particles with energy of the order of $\langle\varphi\rangle$ would be degraded in $\ll t_0$ down to $\sim 10^5$GeV by pair production on the non-thermal radio-wave background and microwave background; below this energy (corresponding to pairs produced just over the peak of the blackbody) the mean free path for this process exceeds a Hubble length, and pairs lose most of their energy by inverse Compton scattering on the microwave photons. The resulting γ-ray spectrum peaks at 10^5GeV with $\Omega_\gamma \simeq \varepsilon$ and falls off like $\Omega_\gamma \propto E_{pair} \propto E_\gamma^{1/2}$ at smaller energies. Observations of cosmic rays near the peak energy constrain ε to be $<\Omega_\gamma \leqslant 10^{-7}$.

Thus very small values of W are already ruled out if the string scenario is to work at all. Recent simulations also indicate that W is probably not smaller than about 10% (A. Albrecht and N. Turok, in preparation), so the gravitational wave background given by equation (6) is a fairly firm prediction of the string scenario. Apart from the uncertainty associated with W, the other major numerical uncertainty in estimating their backgrounds lies in the probability of loop formation. We have assumed above that 1/2 loop of radius ct forms, per spherical volume of radius ct, when the expansion rate is $H = t^{-1}$. The actual number could be smaller than this, but not by very much; this is another question which can be answered using numerical simulations.

Detection of gravitational waves

We base our discussion on detecting gravitational waves using the millisecond pulsar from earlier work[13–15]. Suppose we observe a clean pulsar for a time T, and, after allowing for known intrinsic period variations of the pulsar ($\dot{P}$ and $\ddot{P}$) and for standard ephemeris corrections, we find a mean-square timing residual $\langle R^2\rangle$ (that is, a mean square phase residual $\langle R^2\rangle (P/2\pi)^{-2}$, where P is the pulsar period). Such a residual can be produced by a stochastic background of gravitational waves; in fact the residual produced by waves with angular frequencies higher than α/T is[14]:

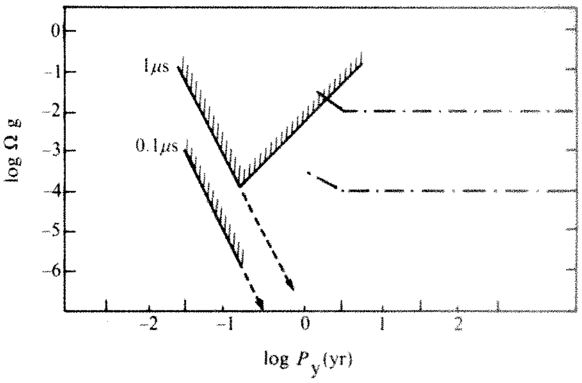

Fig. 2 Current and projected sensitivity of millisecond pulsar timing to gravitational wave background at different wavelengths. Curves are plotted for $\alpha = 2\pi$, $T_y = 1$, and $R = 1$ and 0.1 μs; dotted lines show expected improvement as data accumulation time T increases, for constant R. Improvement at shorter periods may also be expected by distinguishing various forms of noise in the timing residuals. Limits at larger periods arise from cubic residuals induced by long-wavelength waves. Also shown is the projected optimal sensitivity (dot-dash lines) of the binary pulsar if its orbital clock can be calibrated (the two estimates correspond to different signs for the clock residuals, which are limited by different effects[14,15].)

$$\langle R^2\rangle = \frac{32\pi}{3}\rho_c \int_{\alpha/T}^{\infty} d\omega \frac{\Omega_g(\omega)}{\omega^5}\left(1 - \frac{\sin \omega T}{\omega T}\right) \tag{9}$$

assuming isotropy and averaging over random phases and polarizations.

Using $H^2 = 8\pi G\rho_c/3$, and assuming $\Omega_g = \text{const}$ and $\alpha > 1$, this becomes

$$\Omega_g = \langle R^2\rangle T^{-4}\alpha^4 H^{-2} \tag{10}$$

(where all of the numerical coefficients have cancelled), or in units appropriate to the millisecond pulsar 1937+21 (refs 16, 17, and J. H. Taylor, personal communication)

$$\Omega_g = 10^{-7} h_{100}^{-2} \alpha^4 T_y^{-4} R_{\mu s}^2 \tag{11}$$

where T is measured in yr, and R in μs. Currently, pulse arrivals are only measured to an accuracy of $R_{\mu s} \sim 1$ because of time variations in the pulse spectrum induced by interstellar scintillation, which lead to imperfect removal of the effects of interstellar dispersion. However, instrumental improvements will probably reduce $R_{\mu s}$ to $\leqslant 0.1$.

Even the millisecond pulsar is not 'clean' in the above sense, because of residuals introduced by secular effects whose intrinsic parameters are unknown, such as the $\dot{P}$ of the pulsar, which must be fit to the data. One really needs to know the value of Ω_g which would be likely (at a given confidence level) to have produced residuals in excess of those which remain after one has subtracted a best-fit quadratic from the raw residuals. Thus, in using real pulsar data to set an upper limit on Ω_g, the 'safe' choice of α, and that of ref. 14, is $\alpha = 2\pi$ (wave period at cutoff = period of observation), because waves of this high a frequency could not accurately mimic a simple quadratic fit. This is perhaps the first instance in which a precise statistical analysis[23] of these limits is worthwhile, as the constraint on string models is such a sensitive function of α. Meanwhile, Fig. 2 presents an estimate of the current and projected sensitivity of the pulsar observations.

The prospects for achieving levels where string models will be seriously constrained are apparent from the above formulae, which yield

$$\varepsilon < 2.5 \times 10^{-7} (T_y/\alpha)^{-8} R_{\mu s}^4 \qquad (12)$$

In this formula, R is the residual after fitting for known secular effects, and may begin to increase with time due to some source of noise other than gravitational waves. However, if R does not increase too rapidly, even safe choices of α only require longer integrations (of the order of α yr) to reach the level where values of ε required to produce galaxy clustering gravitationally could be ruled out with a high level of confidence.

The predicted spectrum of gravitational radiation leads to residuals increasing quite rapidly with time—at least as fast as $R \propto t^2$, somewhat faster for $\varepsilon \leqslant 10^{-6}$. Variations in interstellar electron density lead to residuals which increase only as $R \propto t^{0.8}$, and in any event have a spectral signature which aids in their removal[18]. Imperfections in the terrestrial clock standards and Solar System ephemeris are an important source of error; they are currently at the level of ~0.3 μs over 1 yr) (D. C. Backer, personal communication). A confident detection of gravitational waves probably requires correlating residuals with other equally clean pulsars so the possibility of intrinsic pulsar variations, and the effects just mentioned, can be removed.

It is also possible that the generation of Earth-based gravitational-wave detectors (~5-km laser interferomers) could detect a stochastic background with $\Omega_g \simeq 10^{-7}$ at $P \sim 10^{-2}$–10^{-3} s. With $\Omega_g \simeq h^2(PH_0)^{-2}$, this requires a broad-band sensitivity to metric deformations $h \simeq 10^{-23}$–10^{-24}.

Dynamical friction

Loops are born with initial centre of mass velocities v_i close to the speed of light, because of the acceleration given by the last intercommute which formed them and subsequently slow time $v \propto a^{-1}$ due to the expansion. Loops also suffer dynamical friction on cold collisionless matter[19,20]. The dynamical friction rate is about

$$t_{df}^{-1} \simeq 2\pi^{3/2} G^2 \rho M \ln \Lambda / v^3 \qquad (13)$$

where v is the peculiar velocity of the loop and $\Lambda \cong v/R_l$ is the range of relevant impact parameters. If $t_{df} < H^{-1}$, the peculiar velocity of a loop decays rapidly to the velocity dispersion of the background material. This occurs if

$$(Ht_{df})^{-1} \cong v_i^{-3} R_l H(a(t)/a(t_i))^3 \varepsilon \ln \Lambda \qquad (14)$$

exceeds unity. For a matter-dominated universe of cold matter, loops with initial γ factors of the order of unity stop just before they decay at $t \simeq \varepsilon^{-1} R_l$.

(There is also an additional direct dynamical friction on strings moving through matter due to the 'wake' of material deflected behind it[20]. This dissipation is important only for one or two oscillations after a loop enters the horizon, although it may produce observable discontinuities in the microwave background temperature[21].)

However, the dynamical friction is much less effective during the early radiation-dominated phase. If the background medium is treated as collisionless particles with speed $\tilde{v}$, then the dynamical friction slowdown time scale for a loop moving with speed $v < \tilde{v}$ is independent of v (and proportional to $\rho^{-1} \propto t^2$). For a given ρ this time scale is longer by $(\tilde{v}/v)^3$ than it would be if the background particles were cold. Dynamical friction is reduced further for subsonic motion of a shallow potential well through a collisional gas[22] (such as the baryon + photon fluid before recombination). Thus, in the early universe it is the neutrinos, and not the photon-plus-baryon fluid, which produce the main drag. Dynamical friction is never efficient before recombination except in a model containing cold dark matter.

The anisotropy in the gravitational wave energy (and momentum) radiated in a single oscillation may be of the order of unity and, therefore, a recoil velocity of $\Delta v_s \cong \varepsilon$ is induced by each oscillation[5]. The cumulative effect depends on whether there is long-term stability in the mode of oscillation and its orientation. If the oscillations are strictly periodic (at least for a time comparable with the gravitational wave decay time scale), then the radiation is repeatedly beamed in exactly the same direction producing an acceleration $\simeq c/t_{dec}$. Thus a loop initially slows down like $v \propto a^{-1}$, reaches a minimum velocity $v_{min} \simeq \varepsilon^{2/5} v_i^{3/5}$, and shoots up to a velocity $\sim c$. In this case, loops with $v_i \simeq c$ never slow down sufficiently for dynamical friction to have any effect. In the opposite extreme, when successive oscillations are completely uncorrelated, the velocity random walks, and can build up only to $\sim \varepsilon^{1/2} c$ on the overall gravitational wave time scale. Real loops lie between these extremes.

Consider now what happens if we include both dynamical friction and recoil forces on a loop. The recoil velocity attainable in a time $t_{df}(< t_{dec})$ is of the order

$$v_c = c(t_{df}/t_{dec}) \min[1, (t_{coh}/t_{df})^{1/2}] \qquad (15)$$

where t_{coh} is the effective coherence time for the oscillations. If this velocity exceeds $\tilde{v}$, then the loop can run away in the sense that dynamical friction will never again be important. In the opposite case, where $\tilde{v} > v_c$, recoil will accelerate a loop to the point where the dynamical friction just damps the energy being added by recoil, rather like brownian motion in a viscous fluid. The actual value of $\tilde{v}$ is unknown, but in the case of cold dark matter such as axions could be arbitrarily small.

A loop whose gravitational radiation recoil is $\ll c/t_{dec}$, or whose initial velocity is sufficiently small, may 'accrete' a halo of matter around it. A loop can accrete its own mass when it slows to the Hubble velocity across a mass of matter equal to the loop mass. For $v_i \leqslant \varepsilon_c^{1/6}$ this occurs by redshifting before coherent recoil begins to take effect, but for $v_i \simeq c$ it occurs at $\simeq t_{dec}$, and even then only if $v_c < \tilde{v}$. The depth of the potential, and the total mass accumulated, depend on the details of when a loop actually slows.

Would the recoil from gravitational radiation eject a string loop from a virialized system? Even if recoil acts in a constant direction, this requires the recoil to produce an acceleration which is sufficient for it to break out of the potential well—that is $\varepsilon/l > v_{vir}^2/l = (M_{matt}/M_l)\varepsilon/l$. Thus a string cannot (unless it breaks into two) escape from a potential well which it does not dominate, although the recoil may cause it to reside away from the centre of the potential well. The effect of the beaming would be to cause the entire virialized system to recoil.

Dissipative heating by oscillating string

After accreting a halo of matter around itself, how does a loop interact with the ordinary matter bound to it? Can gravitational coupling of a loop to ordinary matter enable it to dissipate its rest mass more quickly than an isolated loop?

Goddard *et al.*[24] discovered that, surprisingly, strings of constant invariant length—for our purposes, this means perfectly nondissipative loops, with no gravitational interactions—obey a perfect nondissipative linear wave equation, even for large-amplitude waves. The physical reason for this behaviour is that, locally, the inertia and the tension of the string must always be exactly orthogonal because of restrictions imposed by Lorentz covariance. As a consequence, Kibble and Turok[8] showed that the motion of such a perfect loop is described by advanced and retarded waves travelling with arbitrary waveforms (except that some will lead to self-intersection) in the two directions around the loop. Because the solutions are exactly periodic, the loop traces out repeatedly the same contorted surface, and in fact has a time-averaged gravitational field equivalent to a surface whose local mass density acts like the square of the local transverse velocity[25]. Perfect coherence is maintained indefinitely, so the orientation of this surface is stationary for a perfect loop in a particular Lorentz frame of reference.

We have already seen that the long-term coherence of the direction of gravitational beaming makes a crucial difference in their behaviour (whether they rocket off or whether they stop and accrete matter). Now we find that this coherence is also of crucial importance for the dissipative interaction of loops with matter, because whereas a perfect loop has vanishing power at frequencies $\ll R_l^{-1}$ even a slight perturbation can generate components which vary over a longer time scale, comparable to the orbital time scales of stars. This allows for much more efficient coupling.

A string undergoing exactly periodic oscillations will, in effect, produce a quadrupole (newtonian) component of the gravitational potential which oscillates on a time scale R_l. This time scale is very short compared with the dynamical time scale (in most applications), so the effect is merely to produce small amplitude quasi-periodic shear distortions. Let the mass of (non-string) material within a sphere of diameter R_l be $x \times$ (mass of string loop). Then if $x < 1$, the gravitational binding is due to the string; otherwise the string is just a perturbation:

$$v_{\rm vir} \cong \varepsilon^{1/2} \times \max\,[1, x^{1/2}]c \qquad (16)$$

The velocity perturbation induced by the string in a time R_l is $\Delta v = \varepsilon$ (this is true for all values of x, though not completely obviously so). The corresponding shear amplitude is $\sigma \simeq \varepsilon$.

The amount of dissipation depends on the ratio $y = t_{\rm coll}/R_l$ where $t_{\rm coll}$ is the particle collision time. If this is $\gg 1$ (as, for instance, in stellar-dynamical systems) then the dissipation is small; also, if it is $\ll 1$, so that the pressure remains isotropic, there is again no dissipation. The dissipation is maximized if $y \simeq 1$, but even then the internal energy of the cloud is increased by only $\Delta\sigma/\sigma \simeq \sigma^2$ per oscillation. There are two contexts when we would indeed expect $y \simeq 1$: hot gas in clusters of galaxies, when the ions and electrons have mean free times against Coulomb scattering of order l/c; and pre-combination baryon clouds of $\simeq 10^6 M_\odot$ where the photons provide the main internal pressure, and have mean free paths of order the scale of the system. The motion of the loop also leaves a 'wake'[20], or shear-free velocity perturbation $\Delta v \simeq \varepsilon$ normal to the swath swept out by the string. The energy dissipated from this effect would also be of order ε^2 per oscillation, for $y \geqslant 1$ and $x \leqslant 1$.

As the strings decay through gravitational radiation after $\sim \varepsilon^{-1}$ oscillations, this suggests that fractional change in the energy content of a virialized system due to the oscillations of a perfect loop is negligible (a fraction $\leqslant \varepsilon^{1/2}$ of the binding energy of the matter).

Gravitational interactions of the loop's mean newtonian quadrupole field are likely to have much stronger effects, but their character depends strongly on the long-term coherence over many oscillations. For strings of the type discussed by Kibble and Turok, the orientation and amplitude of the time-averaged newtonian quadrupole moment probably remains coherent over a time $\sim t_{\rm dec}$ if gravitational radiation losses dominate. The surface swept out by the string thus forms a rigidly fixed gravitating shell. If matter in its vicinity has a rotating ellipsoidal figure, the loop will torque the matter through dynamical friction (even if $x > 1$) until it is rotating by an angle $\simeq \varepsilon^{1/2}$ per orbital time.

Other types of string not obeying strict local covariance are likely to be less coherent than these loops. The optimum time scale $t_{\rm coh}$ for the coherent variation of the newtonian quadrupole to interact most strongly with matter is, of course, $t_{\rm coh} \simeq t_{\rm vir}$; in this case the string could, in principle, disperse the matter within one orbital time, if $x \leqslant 1$. However, it is possible that the coherence time is very short compared with $t_{\rm vir}$. The extreme case—and the case of weakest coupling for short $t_{\rm coh}$—is to set $t_{\rm coh} \sim R_l$. The main effect is then contributed by variations in the loop's quadrupole moment averaged over time $T \simeq t_{\rm vir}$; the matter now experiences a randomly oriented shear distortion $\sigma \simeq \varepsilon^{1/4}/\max\,(1, x^{3/4})$ every orbital time. Moreover, the distortion is dissipative even if $t_{\rm coll} \gg t_{\rm vir}$ because of violent relaxation. We then have a fractional increase in the matter's energy of order $\sigma^2 \simeq \varepsilon^{1/2}/\max\,(1, x^{3/2})$ every orbital time, which for $x \leqslant 1$ amounts to its entire binding energy during the lifetime of the loop. The interaction of a loop with the central galaxy in a cluster, for example, would be sufficient to evaporate a substantial fraction of its matter in a Hubble time into an extended envelope. The loop could also provide a significant heat source for the cluster gas, although maximal dissipation would now occur for $t_{\rm coll} \simeq t_{\rm vir}$.

Minimum value of ε

It is possible that loops would establish 'seeds' of some kind (meaning astrophysical sources of energy) even if ε were too small to have a direct influence on galaxy clustering. The energy sources could then be used to generate clustering by some secondary process.

A minimum value of ε for which anything would happen even after decoupling is that for which $T_{\rm vir} \simeq T_{\rm rad}$, because matter cannot cool radiatively below $T_{\rm rad}$ and if it can be pressure supported at that temperature against a loop's gravity no collapse occurs. Thus at $z = 30$ (say) $T_{\rm rad} \cong 100$ K so baryon clouds with $\delta\rho/\rho > 1$ form around loops even if $\varepsilon \simeq 10^{-12}$ and the vacuum expectation value is as small as $\langle\varphi\rangle \simeq 10^{-6} m_{\rm p} \simeq 10^{13}$ GeV; it is sufficient to have $v_{\rm vir} \simeq 1$ km s^{-1}. However, this condition is not sufficient for further collapse and fragmentation. The matter heats up to $T_{\rm vir}$ and again nothing happens unless there is a cooling mechanism at that temperature which can permit the gas to radiate its binding energy in a free-fall time. Various authors have considered rates for cooling in primordial gas, in which cooling is dominated by molecular hydrogen, whose abundance is determined by a charge-exchange reaction catalysed by free electrons. We use the formula given by Blumenthal *et al.*[26], $t_{\rm cool} < t_{\rm dyn}$ if

$$M > M_{\rm cool} = 4.1 \times 10^7 M_\odot \left(\frac{n_{\rm e}/n_{\rm H}}{10^{-4}}\right)^{-0.625} (\Omega h^2)^{-0.917} \times \left(\frac{\Omega_{\rm g}/\Omega}{0.1}\right)^{-1.04} \left(\frac{1+z}{10}\right)^{-2.75} \qquad (17)$$

Strings characteristically generate density fluctuations leading to systems which collapse when $M \simeq \varepsilon^{3/2} M_{\rm H}(z)$. Now $M_{\rm H} \propto z^{-3/2}$ so it is clear that a lower ε is permitted by the cooling argument for higher z. The lowest interesting value of ε will be that which has $M_{\rm cool} \simeq \varepsilon^{3/2} M_{\rm H}(z)$ at the epoch when $T_{\rm vir} = T_{\rm rad}$. This works out to be a redshift $z \approx 100$ and $\varepsilon \approx 10^{-11}$, which may be low enough to be attributable to Peccei–Quinn symmetry breaking. The gravitational wave background for this low an ε is probably (though not necessarily) inaccessible to the millisecond pulsar.

Conclusions

If pulsar limits on $\Omega_{\rm g}$ go below $\sim 10^{-7}$, as it seems will happen soon, then cosmic strings will be pretty well ruled out as candidate sources for any large-scale fluctuations having a significant direct impact on galaxy clustering. At present, however, there is still the possibility that their gravitational waves will start to appear in timing residuals during the next few years. This motivation provides a strong incentive to find at least one other very clean pulsar (preferably several) so that a more definitive signature may be established.

We thank J. Preskill, R. Narayan and M. Wise for helpful discussions, and, particularly, D. C. Backer, N. Kaiser, and N. Turok for important suggestions. This work was supported by a Bantrell Fellowship and by NSF grant 82-14126 at Caltech, and was completed while the authors were participants in the Program on the Formation of Structure in the Universe at the Institute for Theoretical Physics, Santa Barbara.

Sequential late Cenozoic structural disruption of the northern Himalayan foredeep

Douglas W. Burbank* & **Robert G. H. Reynolds**†

Chronologies for the Siwalik molasse and intermontane basins along the southern margin of the Himalaya and Hindu Kush Ranges constrain the timing and pattern of facies migration and structural disruption of the Indo-Gangetic foredeep. This synthesis indicates that quiescent intervals are punctuated by pulses of rapid deformation as thrusting migrates in a stepwise fashion across the foredeep.

THE large-scale southward migration of tectonic deformation away from the axis of the Himalayan orogen has long been recognized[1-4]. Extensive thrusting and nappe development in the vicinity of the Main Central Thrust in the Himalayas and of the Main Mantle Thrust in the Hindu Kush occurred primarily during the middle Cenozoic[4-10]. In contrast, the development of the Main Boundary Thrust (MBT) and related thrusts along the northwestern margin of the Indo-Gangetic foredeep (Fig. 1) has been largely confined to the Plio-Pleistocene[1,2,4,10]. Using magnetic-polarity stratigraphy and fission-track dating, Johnson *et al.*[11] and Opdyke *et al.*[12] have shown that close temporal constraints can be placed on tectonic events recorded by the molasse sediments of the western Himalaya. However, a precise chronology for the succession of events by which thrust faulting disrupted sedimentation within the molasse basin has not been previously delineated. The synthesis presented here is based on the analysis of lithofacies, provenance, and accumulation rates of strata in 14 recently dated sections. Integration of these data reveals the detailed timing of the progressive migration of deformation across the proximal foredeep margin in northern Pakistan and northwestern India during the past 5 Myr (Fig. 1).

Two distinct depositional settings, the largely undisturbed foredeep and the intermontane basins, are found adjacent to the deformational front. In the Indo-Gangetic foredeep, molasse sediments are typically characterized by sheet sandstones representing low-sinuosity, laterally-migrating rivers[13,14], siltstones

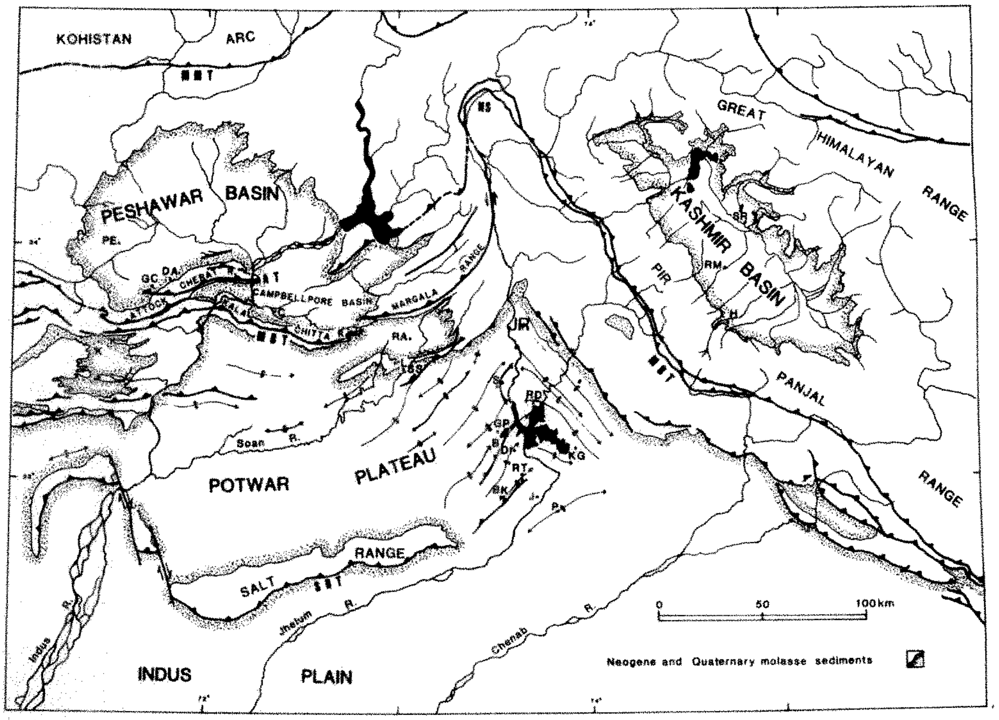

Fig. 1 Map of the northwestern portion of the Indo-Gangetic foredeep, the southern margin of the Himalaya and Hindu Kush, and the major intermontane basins in the vicinity of the North-west Syntaxis (NS). The major anticlinal axes in the deformed molasse sediments, as well as major thrust faults (barbed lines) and strike-slip faults in the region surrounding the Jhelum Re-entrant (JR), are delineated. During the Plio-Pleistocene, structural deformation has progressively migrated southwards across the foredeep in response to the ongoing Indo-Asian collision. Major thrust faults: AT, Attock Thrust; MBT, Main Boundary Thrust; MMT, Main Mantle Thrust; SRT, Salt Range Thrust. Locations of measured and dated stratigraphical sections: B, Bangala; C, Campbellpore; DA, Dag; DI, Dina; GP, Ganda Paik; GC, Garhi Chandan; H, Hirpur; KG, Kas Guma; L, Lei; RD, Rata-Dadial; RT, Rohtas; RM, Romushi; S, Sakrana; SS, Soan Syncline. Other localities: BK, Basawa Kas; J, Jhelum; P, Pabbi; PE, Peshawar; RA, Rawalpindi; SR, Srinagar.

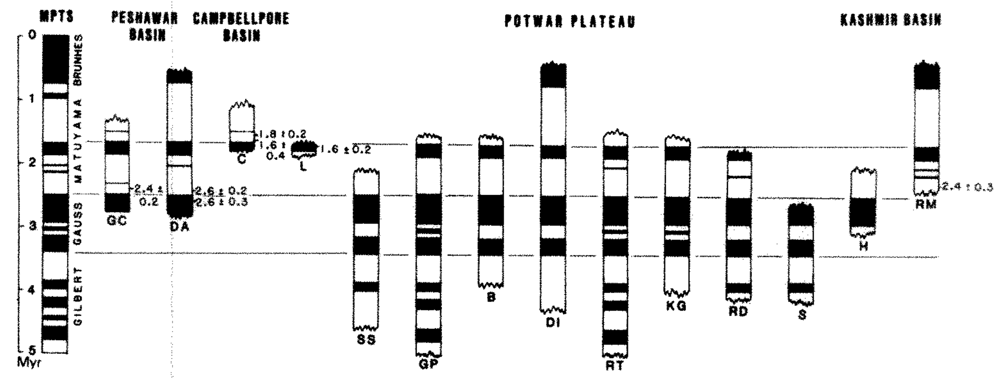

Fig. 2 Comparisons of locally determined magnetic-polarity stratigraphies (MPSs) with the magnetic-polarity time scale[41,42]. Fission-track dates on volcanic ashes are shown with 2σ errors at their appropriate stratigraphical positions. The magnetostratigraphical correlations are based on recognition of identifiable chrons or subchrons and are aided by both fossil occurrences and the frequent presence of prominent ashes straddling the Gauss–Matuyama transition. The fission-track dates from Lei and from the lower ash at Campbellpore are reported in ref. 29. The Soan Syncline section is from ref. 31. For a detailed discussion of other sections and fission-track dates, see refs 13 and 24. The local MPSs are arranged as they would be encountered along a traverse from the Peshawar Basin southeastwards to the Potwar Plateau and then northeastwards to the Kashmir Basin. In order: MPTS, magnetic-polarity time scale; GC, Garhi Chandan; DA, Dag; C, Campbellpore; L, Lei conglomerate; SS, Soan Syncline; GP, Ganda Paik; B, Bangala; DI, Dina; RT, Rohtas; KG, Kas Guma; RD, Rata-Dadial; S, Sakrana; H, Hirpur; RM, Romushi. Note that based on the sediment accumulation rates in the dated portion of the Hirpur sequence, the base of the underlying conglomeratic and mudstone section is interpreted to be ~4 Myr old[19].

with numerous palaeosol horizons developed on broad, interfluvial floodplains[15–17], and subsidiary ribbon sandstones representing higher sinuosity rivers[17]. Lacustrine strata are virtually absent within the molasse sediments[11–17]. The molasse sequence, 6,000 m thick, is exposed in the Himalayan foothills, where it is termed the Siwalik and Rawalpindi Groups[18]. In contrast, the intermontane basins, such as the Kashmir and Peshawar Basins, are dominated by proximal alluvial-fan facies, intermediate braided-river sediments, and extensive high-sinuosity fluvial and shallow lacustrine sediments that extend across the central portion of the basins[19–21]. These sequences occur in tectonically ponded valleys that lie inside the deformational front of the Himalayan fold-and-thrust belt. It is the predominant control on the style and rate of sediment accumulation exerted by the tectonic environment that permits us to unravel the patterns of regional tectonic evolution by dating strategically located stratigraphical sections.

Western limb of Jhelum Re-entrant

The Potwar Plateau represents the outermost and youngest of the series of intermontane basins in the western Himalaya. It is separated from the southernmost ranges of the Hindu Kush by the Peshwar and Campbellpore intermontane basins (Fig. 1). Earthquake-hypocentre distributions suggest that the Peshawar Basin is underlain by a subhorizontal, detachment surface[22,23]. This surface is inferred to continue southward as a largely aseismic detachment beneath the Potwar Plateau and to break the surface at the southern edge of the Salt Range. The Attock Thrust and the MBT (Fig. 1) are inferred to represent splays off this detachment surface[22,23]. Late Cenozoic movement along these thrusts has uplifted the Attock–Cherat Range and the Kala Chitta–Margala Range which define the southern margins of the Peshawar and Campbellpore Basins, respectively (Fig. 1). To constrain the deformational chronology of the northern foredeep, we have dated sections: (1) within the Peshawar and Campbellpore Basins; (2) near the bounding faults; and (3) across the Potwar Plateau.

Along the northern flank of the Attock Range in the Peshawar Basin (Fig. 1), mid-to-late Pleistocene uplift has exposed intermittently the uncomformable contact of the basin-filling sediments with the underlying Oligocene–Miocene bedrock[24,25,43]. Two magnetostratigraphical sections from this area commence in the upper Gauss chron, as indicated by three fission-track dates on ashes straddling the overlying reversal interpreted as

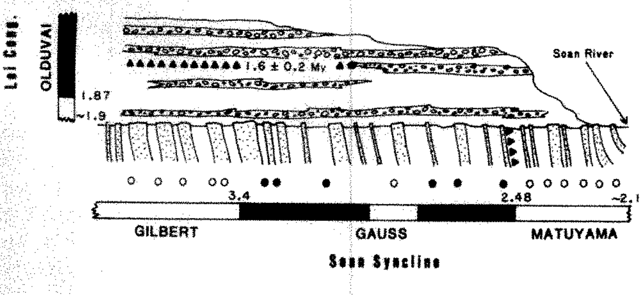

Fig. 3 The northern limb of the Soan Syncline, where nearly vertical strata of typical Siwalik molasse sediments are truncated and overlain by the generally underformed Lei conglomerate. Only the upper portion of >3,000 m of molasse sediments is shown. ▲, Enclosed volcanic ashes. The magnetostratigraphy[31] indicates that these strata encompass the Gauss chron and that the youngest preserved sediments extend into the lower Matuyama chron, probably to ~2.1 Myr. The overlying Lei conglomerate includes an ash dated at 1.6 ± 0.2 Myr (ref. 29) on the basis of which the normal-polarity magnetozone is interpreted as the Olduvai subchron. The base of the Lei conglomerate must predate the Olduvai and is interpreted as ~1.9 Myr. Thus, between 2.1 and 1.9 Myr ago, >3,000 m of uplift and erosion (mean minimum rate of 15 mm yr^{-1}) occurred as the Soan Syncline was strongly compressed in response to thrusting along the MBT.

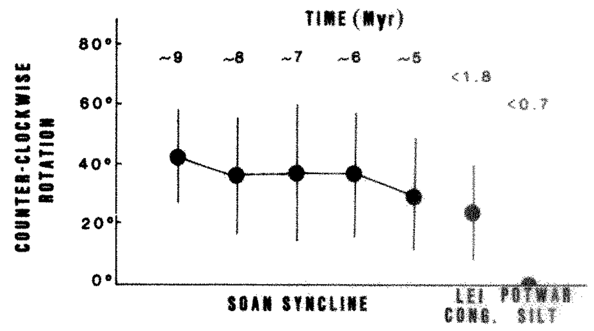

Fig. 4 Post-depositional rotation of foredeep sediments in the vicinity of the Soan Syncline. Amount of rotation is based on the deviation of the mean orientation of the normal and reversed magnetic sites from a given time interval with respect to the theoretical north–south axial dipole. The chronologically constrained data indicate that up to 15° of counterclockwise rotation occurred between 9 and 2 Myr ago. However, the most rapid rotation of over 20° occurred between 1.8 Myr and the present, following the development of the Soan Syncline.

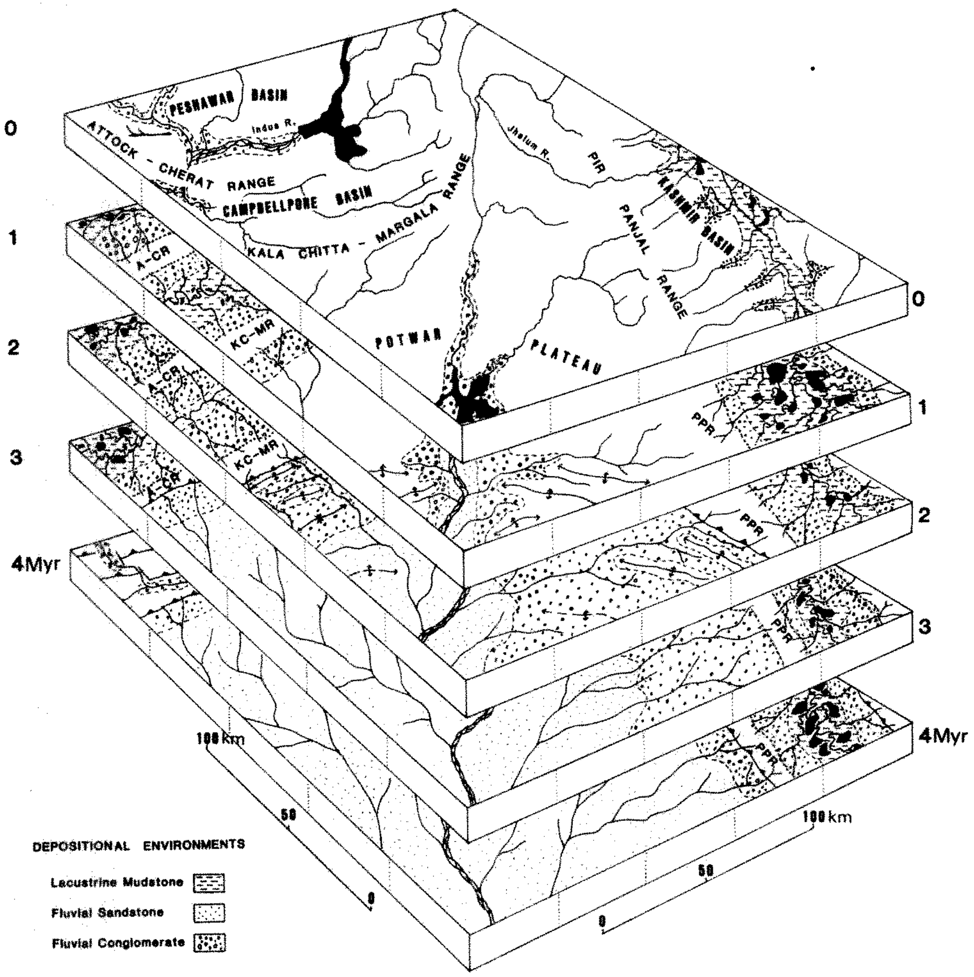

Fig. 5 Reconstructed structural and depositional relationships in the vicinity of the North-west Syntaxis at 1-Myr intervals during the past 4 Myr. Changes in facies relationships and the pattern of structural deformation are depicted adjacent to thrusts active at each interval. The zone of molasse deposition beyond the intermontane basins becomes increasingly restricted as thrusting and anticlinal growth migrate across the foredeep. Conglomerate facies and strong structural deformation in positions proximal to active faults grade laterally to indisturbed sheet sandstones in distal settings. A–CR, Attock–Cherat Range; KC–MR, Kala Chitta–Margala Range; PPR, Pir Panjal Range.

the Gauss–Matuyama transition (Fig. 2). Based on the estimated age of the basal depositional contact at Garhi Chandan, intermontane sedimentation in the Peshawar Basin is inferred to have begun ~3.0 Myr ago. Before this, movement along the Attock Thrust (Fig. 1) had caused uplift of the ancestral Attock Range and generated a tectonic depression on the northern side of the uplifted terrane. This tectonic event ponded the fluvial systems which had previously drained across the region and localized sediment accumulation in the newly formed basin.

The Campbellpore Basin is an elongate depression enclosed by the Attock Range to the north and the Kala Chitta–Margala Range to the south (Fig. 1). Despite the brevity of the sections along the western Haro River[24,26–28] (Fig. 2), the presence of several volcanic ashes permits precise dating of the basin fill[24,29] and indicates that sedimentation in the Campbellpore Basin had commenced by ~1.8–1.7 Myr ago. We can conclude that the thrusting along the MBT (Fig. 1) which uplifted the Kala Chitta Range and delimited the southern margin of the Campbellpore Basin had commenced at least 1.9 Myr ago.

Further information on the onset and duration of thrusting is provided by a section on the southern side of the MBT. The Soan Syncline (Fig. 1) is located ~20 km south of the MBT near Rawalpindi, where it is developed in sediments of the Upper Siwalik Group. The Soan Syncline is strongly asymmetric with a vertically standing northern limb and a gently dipping southern limb[30]. The magnetostratigraphy of the Upper Siwalik sediments in the northern synclinal limb[31] indicates that the youngest deformed strata are ~2.1 Myr old (Figs 2 and 3) and that the sequence, which is >3,000 m thick, extends well into the Upper Miocene[13]. The horizontally-bedded Lei conglomerate unconformably overlies the vertical strata of the northern limb of the syncline. A fission-track date of 1.6 ± 0.2 Myr on an enclosed ash[29] indicates that the normal-polarity interval is the Olduvai subchron and that the oldest strata of the Lei conglomerate are likely to be ~1.9 Myr old (Figs 2, 3).

These chronological data delineate a very brief interval of rapid tectonic deformation in the latest Pliocene. During a period of ~200,000 yr beginning around 2.1 Myr ago, >3,000 m of structural relief was developed and was accompanied by rapid erosion. By 1.9 Myr ago, the deformed sequence had been truncated by erosion, and the Lei conglomerate spread southward across the area (Fig. 3).

We interpret the deformation of the Soan Syncline as a response to the initiation of major movement along the MBT around 2.1 Myr ago. The Lei conglomerate represents the proximal, transgressive facies shed from the rising Kala Chitta–Margala Range to the north. The horizontal aspect of the Lei conglomerate today, the gentle dips (<5°) found in the intermontane sediments of the Campbellpore Basin[22,25,26], and the absence of conglomerates younger than 1.6 Myr (Fig. 2) suggest that major movement along the MBT was short lived and had largely ceased by the end of the Pliocene. Following deposition of the Lei conglomerate, major rotation of the Soan area began (Fig. 4). We view this rotation as coincident with the propagation of the detachment surface[22,23] beneath the Potwar Plateau towards the modern Salt Range and with the resulting development of the Potwar Plateau as an allochthonous unit.

During the Pleistocene, tectonic disruption migrated systematically southwards across the central and eastern Potwar Plateau. Three magnetostratigraphical sections[13,32] from the eastern Potwar (Fig. 2) constrain this history of tectonism. Two intervals of conglomeratic sedimentation are present in most sections: one in the upper portion of the comformable molasse sequence (sometimes intraformational in nature) and one overlying the deformed and eroded molasse strata. The first appearances of conglomerates are time-transgressive events related to either an influx from extrabasinal, bedrock uplifts or intrabasinal deformation. In addition, the timing of initiation of conglomeratic sedimentation at a given section is a function of the spatial relationship between the section and the former axis of

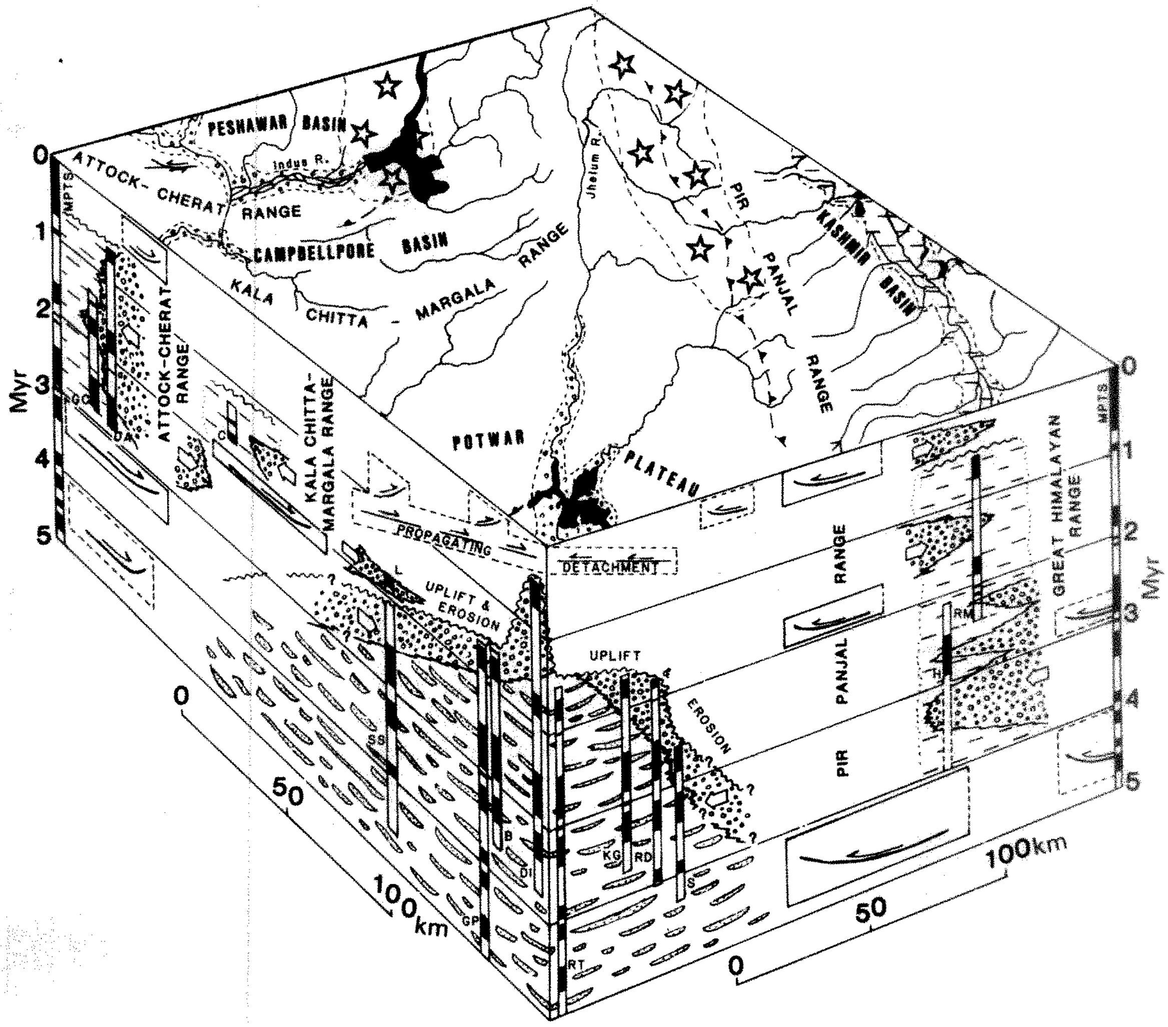

Fig. 6 Time–distance block diagram of the Himalayan foredeep and adjacent ranges in the vicinity of the North-west Syntaxis. The vertical dimension extends back to 5 Myr. The dated sequences described in this study and shown in Fig. 2 are depicted in their chronological range and are projected from their geographical location on to the transects defining the sides of the block. The abbreviations next to each magnetic column are as in Figs 1 and 2. Medial sections such as Sakrana (S) could be projected onto either face. The northeastern face is chosen here based on the affinities of the conglomerates at Sakrana with those from Rata–Dadial (RD) and Kas Guma (KG). For each of the stratigraphical sections, generalized depositional and facies relationships are shown in their proper chronological position (for example, the southward progradation of conglomerates from Sakrana across the eastern Potwar Plateau after 3 Myr). The intermontane basins are dominated by low-energy (largely lacrustine) facies punctuated by conglomeratic influxes. Two broad phases of molasse sedimentation across the Potwar Plateau are shown: a channel-and-floodplain interval succeeded by late-stage polymictic conglomerates. Large, open arrows indicate the prevailing palaeocurrent directions at different times. The boxes enclosing a thrust-fault symbol delineate both the spatial and chronological intervals over which the thrusts are interpreted to have been active. Dashed boxes show less well constrained periods of thrusting. On the left-hand panel, thrusting, folding and intermontane basin formation are seen to progress in a stepwise fashion from the Peshawar Basin to the south-east between 4 and 1 Myr ago. On the right-hand panel, three intervals of uplift in the vicinity of the Pir Panjal Range have defined the Kashmir Basin, controlled palaeocurrent patterns, and deformed the adjacent foredeep to the south-west. The surface of the block illustrates active, present-day processes. Deposition is largely restricted to the axial portions of the intermontane basins and narrow floodplains. Regions of high seismicity within 10–15 km of the surface[22] are shown by stars. Presently- or recently-active faults that break the surface seem to be associated with shallow seismicity.

local fluvial deposition. Intraformational conglomerates first appear at Ganda Paik and Bangala (Fig. 1) about 2.0–1.9 Myr ago, synchronous with the inferred movement along the MBT. At the same time, decreasing rates of sedimentation are observed at Ganda Paik, Bangala, and, farther to the south, at Dina (Fig. 1), where extrabasinal conglomerates first appear around 1.6 Myr ago. The youngest comformable molasse strata in each section provide a limiting date on the cessation of sedimentation, as a wave of folding, uplift and erosion traversed the region. Thus, to the south-east of the Soan Syncline where deformation began around 2.1 Myr ago, the topmost conformable strata are progressively younger at Ganda Paik and Bangala (~1.6–1.5 Myr) and at Dina (~0.5 Myr). The youngest strata preserved farther south-east at Rohtas (Fig. 1) are ~1.5 Myr old. However, the presence of molasse strata as young as 0.4 Myr on the Rohtas anticline some 10–15 km farther south-west[11,12] (BK, Fig. 1) suggests significant truncation of the Rohtas section.

Eastern limb of Jhelum Re-entrant

The Kashmir intermontane basin is separated from the Indo-Gangetic foredeep by the thrust-faulted Pir Panjal Range (Fig. 1). South of the Pir Panjal, the Siwalik molasse is well exposed in a series of thrust-cored anticlines where measured and dated stratigraphical sections record the history of fluvial systems flowing from the Himalayas. Although the detailed timing of tectonic events in the enclosing ranges and the bounding foredeep cannot be delineated as precisely as in the region to the west, three intervals of deformation can be discerned in both the intermontane sediments of Kashmir and the molasse sediments to the south.

In Kashmir, the basin-filling Karewa Formation[19,21,33–36] is >1,300 m thick. Magnetostratigraphical sections from Hirpur and Romushi (Figs 1 and 2) indicate that Karewa sedimentation spans the interval from ~4 Myr to the present[19]. This deposition began as a response to the initial emergence of the ancestral Pir Panjal Range $\sim$4.5 Myr ago. Although molasse sedimentation across the Potwar region to the south continued uninterruptedly during this interval[13], major changes in clast lithologies in the molasse and in drainage patterns (from east-flowing to south-flowing)[13,37] signal the concomitant onset of structural development of the Jhelum Re-entrant[38]. In addition, for the first time in Upper Siwalik sediments, polymictic conglomerates appear in abundance, reaching Sakrana (Fig. 1) by 3.1 Myr ago and prograding southwards across Rata-Dadial (2.5 Myr) and Kas Guma (2.1 Myr). This onslaught of conglomeratic sedimentation appears to be a time-transgressive response to the initial uplift of the Pir Panjal Range.

Concurrently in Kashmir, palaeocurrent indicators[19] suggest that pulses of uplift, presumably thrust-related, occurred along the northeastern margin of the basin until $\sim$2 Myr ago. Subsequently, diminution of this thrusting[38] and accelerated uplift of the Pir Panjal Range redirected palaeocurrents towards the north-east. This interval of tectonism is synchronous with that previously described in the north-central Potwar and is recorded concurrently by a deceleration in molasse sedimentation rates at Rata-Dadial and Kas Guma (Fig. 1). This deceleration is likely to signal the onset of development of the thrust-cored anticlines in the foredeep in response to intensified thrusting and uplift to the north. Subsequently, progressive uplift and erosion spread southwards across the eastern Potwar, as evidenced by the youngest comformable strata at Sakrana ($<$2.7 Myr), Rata-Dadial ($<$1.8 Myr) and Kas Guma ($<$1.4 Myr). The youngest deformation in the Potwar is recorded in sections at Pabbi[32,39], Basawa Kas[11,12] (P, BK; Fig. 1) and Dina, where erosion supplanted sedimentation $<$0.5–0.4 Myr ago. This third phase of tectonism is contemporaneous with the most recent interval of rapid uplift, totalling 1,300–3,000 m, of the Pir Panjal Range in southern Kashmir[19].

Synthesis

The use of magnetostratigraphy in conjunction with fission-track dating provides an insight into the chronology of the late Cenozoic structural disruption of the northern margin of the Indo-Gangetic foredeep in northern Pakistan and India. Figure 5 illustrates the reconstructed depositional and tectonic conditions in 1-Myr increments between 4 Myr and the present. The time–space perspective diagram in Fig. 6 illustrates the concurrent evolution of both arms of the North-west Syntaxis.

Intermontane basin development commenced in Kashmir 4–5 Myr ago and progressed contemporaneously with major changes in palaeocurrents and provenance in the adjacent foredeep. Dated sequences in the Peshawar and Cambellpore intermontane basins and in the Soan Syncline delineate the sequential southward migration between $\sim$3.0 and 1.8 Myr ago of major thrust faulting, uplift, and the concurrent development of intermontane basins on the back side of the uplifted terranes. During this time interval, the locus of thrusting shifted some 50 km to the south. The duration of significant movement along the major thrusts (Attock, MBT) is envisaged as rather brief ($<$0.5 Myr). Contemporaneous deformation and erosion of sedimentary sequences in front of the thrusts often occurred at rapid rates ($\geq$15 mm yr^{-1}). Subsequent to the development of the imbricated, thrust-bounded ranges and basins in northern Pakistan and to a second pulse of uplift in Kashmir, the locus of major deformation continued migrating towards the south, where it caused folding, faulting and rotation of the Potwar Plateau[13,32,40], and propagation of the detachment surface to the Salt Range.

Whereas the initial development of the Kashmir and Peshwar Basins does not appear to be synchronous, a pulse of deformation associated with thrusting along the MBT is manifested across a broad region of the northwestern foredeep around 2–1.5 Myr ago. Development of the Campbellpore Basin, snapping shut of the Soan Syncline, and renewed uplift of the Pir Panjal Range were apparently contemporaneous with the disruption of molasse sedimentation across the Potwar Plateau as thrust-cored anticlines began to grow along the northern foredeep margin.

Conclusions

Because of the temporal resolution provided by magnetostratigraphical studies, the timing and duration of tectonic and sedimentary events in the northern Himalayan foredeep can now be reconstructed with greater detail than was previously possible. The chronological data emphasize the sporadic nature of tectonism in this collisional setting. Although the rate of convergence of the Indian subcontinent with Eurasia[41] appears steady during the studied time interval, this detailed reconstruction of the northwestern Himalayan foredeep indicates that prolonged periods of quiescence and uniform sedimentation were punctuated by brief, intense intervals of deformation as the locus of thrust faulting encroached in a stepwise fashion on the adjacent foredeep. This sporadic tectonism may be regarded as the pulse of an orogenic process which, when integrated over time intervals in excess of 1 Myr seems to be continuous.

This research was suppoted by grants from the Geological Society of America, Marathon Oil, the Shell Foundation and Amoco International to D.W.B. and the NSF (INT 8019373 and EAR 8018779) to Dartmouth College. The assistance of R. A. K. Tahirkheli of Peshawar University is gratefully acknowledged. Many of these results are derived from doctoral studies completed by us while at Dartmouth College. Discussions with G. D. Johnson, N. M. Johnson and P. K. Zeitler contributed greatly to this research.

Occurrence of a transposition from the X-chromosome long arm to the Y-chromosome short arm during human evolution

DXYS1, *a site showing greater than 99% DNA sequence homology between the human X and Y chromosomes, maps to the X long arm and to the Y short arm. In great apes, sequences homologous to* DXYS1 *are found only on the X chromosome. These findings suggest an X–Y transposition during human evolution.*

IT is widely held that the mammalian X and Y chromosomes are in part homologous as a consequence of their evolution from a completely homologous pair[1,2]. Terminal pairing of the short arms of the human X and Y chromosomes during meiosis is taken as evidence of such partial homology[1,3–8]. Here we demonstrate that human X–Y sequence homology is not limited to the pairing portions of the sex chromosomes. Moreover, X–Y homology at the locus *DXYS1* appears to be the result of a recent transposition from the X to the Y chromosome.

Chromosomal sublocalization of *DXYS1*

DXYS1 was the first site of single-copy DNA sequence homology to be found between the human X and Y chromosomes[9,10]. A *Taq*I restriction fragment length polymorphism (RFLP)[11] at *DXYS1* consists of allelic X-linked fragments of 11 and 12 kilobases (kb) and a male-specific (Y-specific) 15-kb fragment. The complete association of the 15-kb fragment with the Y chromosome and the strictly X-linked inheritance of the 11- and 12-kb fragments imply that X–Y recombination does not normally occur (or is lethal) at *DXYS1*. Given the long-standing hypothesis that meiotic recombination between the pairing regions of X and Y chromosomes occurs frequently[12], we set out to determine whether *DXYS1* maps to the pairing regions of the sex chromosomes.

To localize *DXYS1* on the X and Y chromosomes, we carried out *in situ* hybridization of a probe defining *DXYS1* [pDP31, a subclone of probe 5 (Fig. 2*a*) into pBR322; ref. 9] to human metaphase chromosomes. As illustrated by the representative cell in Fig. 1*a*, pDP31 showed significant hybridization to the proximal portion of the long arm of the X chromosome and to the short arm of the Y chromosome. Of 72 cells hybridized at 100 ng ml^{-1} probe DNA and exposed for 5–11 days, 47% exhibited grains on the proximal long arm of the X chromosome and/or on the short arm of the Y chromosome. These grains represented 20% of all label observed in the 72 cells. Experiments were then done to refine the sublocalization of *DXYS1* by hybridization of the ^{3}H-labelled probe at a low concentration (12 ng ml^{-1}) followed by exposure for 46 days. Analysis of grains on labelled X and Y chromosomes (Fig. 1*b*) indicated sublocalization of *DXYS1* to Yp and to a region on the X that includes the lower half of band q13 and the upper half of q21 (most likely Xq13.2–q21.2).

To provide a second, independent sublocalization of *DXYS1* on the human X and Y chromosomes, genomic DNAs were

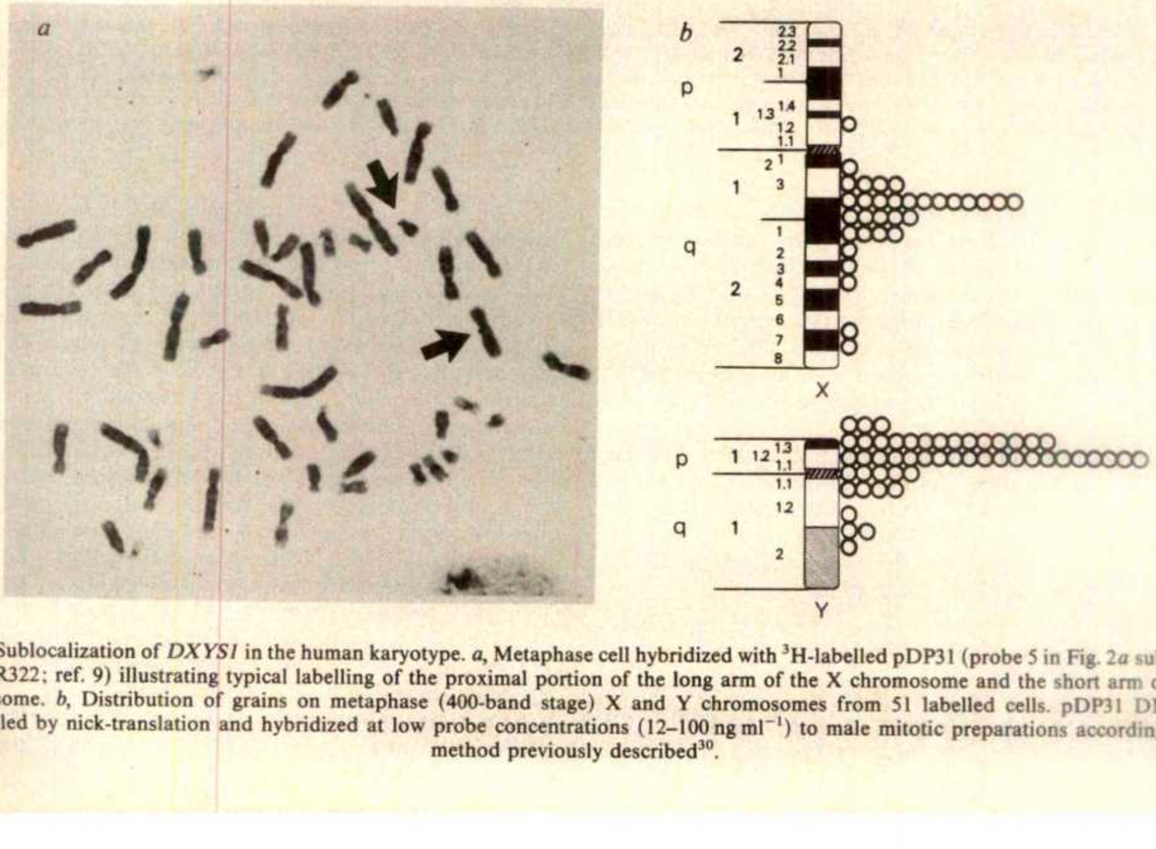

Fig. 1 Sublocalization of *DXYS1* in the human karyotype. *a*, Metaphase cell hybridized with ^{3}H-labelled pDP31 (probe 5 in Fig. 2*a* subcloned into pBR322; ref. 9) illustrating typical labelling of the proximal portion of the long arm of the X chromosome and the short arm of the Y chromosome. *b*, Distribution of grains on metaphase (400-band stage) X and Y chromosomes from 51 labelled cells. pDP31 DNA was ^{3}H-labelled by nick-translation and hybridized at low probe concentrations (12–100 ng ml^{-1}) to male mitotic preparations according to the method previously described[30].

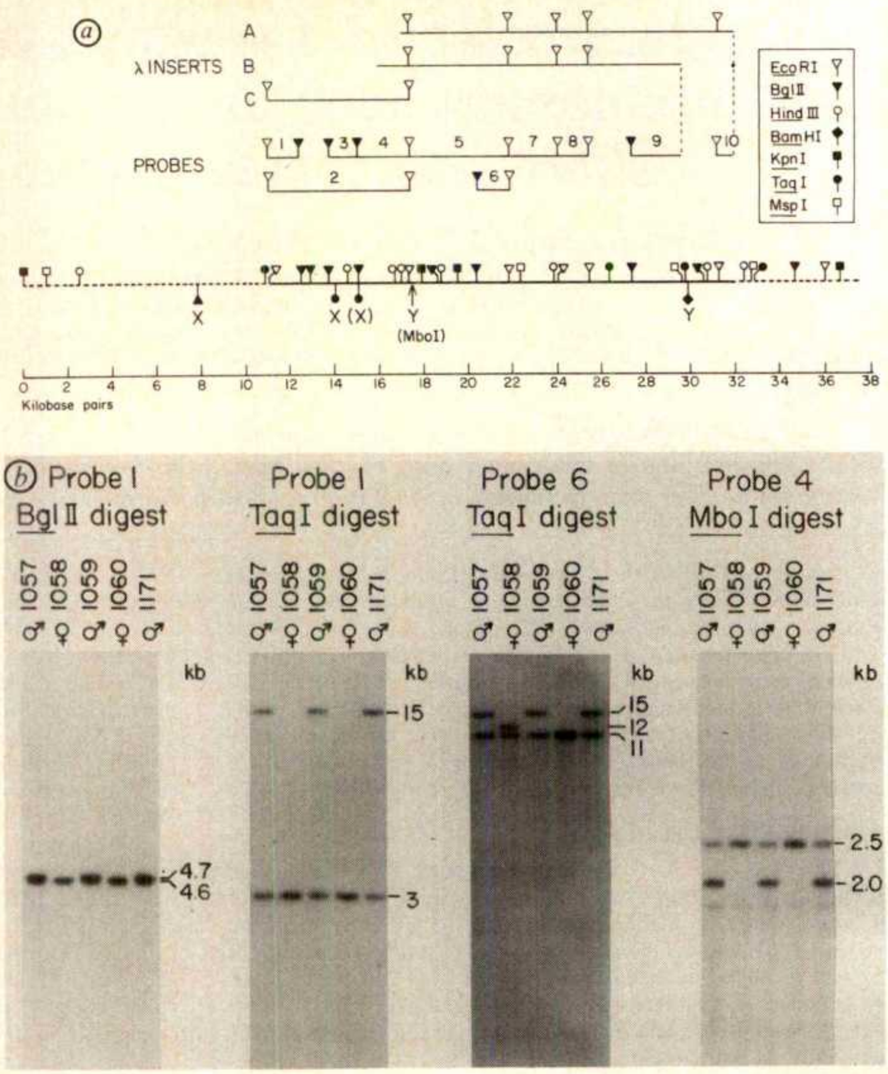

Fig. 2 ***a***, Restriction endonuclease mapping of 36 kb of the human X and Y chromosomes at *DXYS1*. At the top are shown the overlapping human DNA inserts of three recombinant λ phage: A, λ-rHs-3-1; B, λ-rHs-4813; and C, λ-rHs-X6.3. The locations of *Eco*RI restriction sites are indicated. Below the phage inserts are 10 restriction fragments purified from these inserts for use as hybridization probes; terminal restriction sites are indicated. Below the probes is shown the restriction map of the X and Y chromosomes at *DXYS1*. Restriction endonuclease cleavage sites common to the X and Y chromosomes are indicated by symbols above the line. Sites specific to either the X or the Y chromosome are indicated below the line. A Y-specific *Mbo*I site (see text) is shown. Sites within the 21-kb region (solid line) spanned by the three λ clones were mapped by direct analysis of those clones and confirmed by blot hybridization using probes 1–10. Sites outside the region (dotted line) were mapped by blot hybridization using probes 1 and 10. Every site was detected or confirmed by blot hybridization of DNAs from at least nine unrelated males and two unrelated females (nine Y chromosomes and 13 X chromosomes). We have previously reported a Y-linked *Msp*I/*Bgl*II restriction fragment length polymorphism at *DXYS1* (ref. 9); this polymorphism is the result of a tandem duplication on the Y chromosome in some males (D.C.P., in preparation). The map of the Y chromosome shown here is that of the nonduplicated form. No new RFLPs were detected during this study. ***b***, Differential patterns of hybridization of human male and female DNAs with DNA probes for *DXYS1*. These hybridizations detected restriction sites specific to either the X or the Y chromosome.
Methods: Recombinant phage λ-rHs-4813, purified from a human genomic library[31], was the original source of hybridization probes for *DXYS1* (ref. 9). Recombinant phages λ-rHs-3-1 and λ-rHs-X6.3 derive from the same genomic library[31] and from an X-specific library[32], respectively. These two phage were identified by plaque hybridization screening[33] using DNA probes purified from the human insert of λ-rHs-4813. Some of these restriction fragments were subcloned into plasmid pBR322 or an abbreviated derivative (pDP322; D.C.P., unpublished) before use as hybridization probes. Human genomic DNAs were prepared from peripheral leukocytes by the method of Kunkel *et al.*[13]. DNA samples were digested with restriction endonuclease, electrophoresed on 0.75% agarose gels, and transferred[34] to AMF Zetapore paper. Restriction fragments purified from phage λ-rHs-3-1, λ-rHs-4813 and λ-rHs-X6.3 were labelled with ^{32}P by nick-translation[35] and hybridized overnight to the filter-bound genomic DNAs at 47 °C in 50% formamide, 5× SSC (1× SSC = 0.15M NaCl, 15 mM Na citrate *p*H 7.4), 1× Denhardt's (0.02% Ficoll 400, 0.02% polyvinyl pyrrolidone, 0.02% bovine serum albumin), 20 mM $NaPO_4$ *p*H 6.6, 50 μg ml^{-1} denatured salmon sperm DNA, and 10% dextran sulphate. Following hybridization, filters were washed three times for 15 min each at 55–60 °C in 0.1× SSC, 0.1% SDS and exposed at −70 °C for 1–7 days with Kodak XAR-5 film backed by a DuPont Lightning-Plus intensifying screen.

obtained from three rodent–human cell hybrids (characterized by G. Bruns, unpublished results) containing portions of the human X chromosome and from three humans whose cells contain portions of the Y chromosome (ref. 13 and K. Smith and collaborators, unpublished results). Gel transfers of *Taq*I digests of these DNAs were hybridized with *DXYS1* probe 5 (see Fig. 2*a*) and scored for the presence or absence of the X- and Y-specific *Taq*I fragments detected by probe 5. The results of these studies map *DXYS1* to Xq1–q22 and to Ycen–pter (data not shown). In addition, *DXYS1* probe 9 (Fig. 2*a*) was applied to the dosage panel used by Kunkel *et al.*[14] to assign DNA segments to regions of the human X chromosome. By this method, *DXYS1* was mapped to Xq13–q24 (data not shown). These results are consistent with the assignment of *DXYS1* to Xq13-q21 and Yp by *in situ* hybridization.

X–Y restriction mapping

The homology between the X and Y chromosomes at *DXYS1* extends for at least 28 kb[9]. In order to quantitate further the X–Y homology at *DXYS1*, we made a comparative restriction map of the X and Y chromosomes at this locus. A series of neighbouring single-copy restriction fragments were hybridized to gel transfers of restriction endonuclease-digested human male and female DNAs (Fig. 2). In this way, a stretch of 36 kb was mapped in this region. Where no differences were detected in the patterns of hybridization with male and female DNA, it was assumed that the X and Y chromosomes share a common restriction fragment. Indeed, most restriction fragments were found to be identical on the X and Y chromosomes. Of 40 *Eco*RI, *Bgl*II, *Hin*dIII, *Bam*HI, *Kpn*I, *Taq*I and *Msp*I restriction sites that we mapped at *DXYS1*, 36 sites are common to the X and Y chromosomes, one site is specific to the Y, two sites are specific to the X, and one (*Taq*I) site gives rise to the X-linked RFLP which is present on about half of the X chromosomes in Northern European populations, but absent from the Y chromosome. These results establish that the X and Y chromosomes are homologous over an expanse of at least 36 kb at *DXYS1*. We have not detected the termination of this X–Y sequence homology.

Analysis of this region with the restriction enzyme *Mbo*I yields similar results. Of 11 *Mbo*I restriction fragments observed over

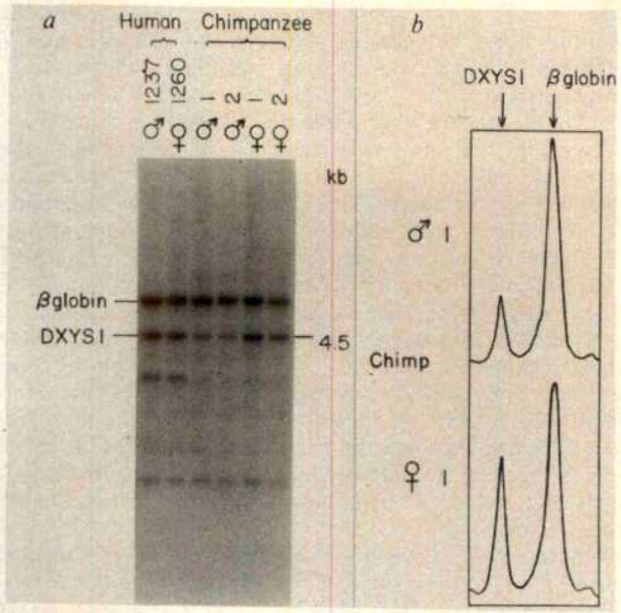

Fig. 3 Male–female dosage at a *DXYS1*-homologous locus in chimpanzee. *a*, Hybridization of *Eco*RI-digested human and chimpanzee male and female DNAs to probes for *DXYS1* and β-globin. Genomic human and chimpanzee DNAs were digested with the restriction endonuclease *Eco*RI, blotted, and hybridized as in Fig. 2*b* with ^{32}P-labelled probe 5 (Fig. 2*a*) and plasmid πSVβ (containing 3.7 kb of human genomic sequence from the β-globin locus; ref. 36). Probe detects a 4.5-kb human genomic *Eco*RI fragment common to the human X and Y chromosomes (Fig. 2*a*). It is also homologous to a 4.5-kb *Eco*RI fragment in chimpanzee. Plasmid πSVβ detects a 5.3–kb *Eco*RI fragment in both human and chimpanzee. In the human, this *Eco*RI fragment contains most of the β-globin gene and derives from chromosome 11. πSBβ also hybridizes to two smaller *Eco*RI fragments in both human and chimpanzee (in man, these are known to correspond to the remainder of the β-globin locus and to the δ-globin locus). *b*, Densitometric tracings of portions of two lanes (chimpanzee male no. 1 and female no. 1) of an autoradiogram produced without an intensifying screen but otherwise identical to that in *a*.

Table 1 Calculations of X–Y sequence divergence at *DXYS1*

Distribution of restriction sites on the X and Y chromosomes

6-base enzymes	m_X	m_Y	m_{XY}	4-base enzymes	m_X	m_Y	m_{XY}
*Eco*RI	6	6	6	*Taq*I	3.5	2	2
*Bgl*II	8	8	8	*Msp*I	2	2	2
*Hin*dIII	6	6	6	Total	5.5	4	4
*Bam*HI	0	1	0				
*Kpn*I	2	2	2	$\bar{m} = 4.75$			
Total	22	23	22				

$\bar{m} = 22.5$

Combined 6- and 4-base enzyme data: $d = 0.0083 \pm 0.0054$

6-base enzyme data only: $d = 0.0037 \pm 0.0038$

The fraction of nucleotides at which the X and Y chromosomes differ at *DXYS1* was estimated using data drawn from the X–Y comparative restriction map of Fig. 2*a* and formulae for 'nucleotide counting' of Nei and Tajima[15]:

$$d = d_1 \frac{\sum_i r_i(\bar{m}_i - m_{XYi})/[\{1-(1-d_1)^{r_i}\}\{2-(1-d_1)^{r_i}\}]}{\sum_i r_i \bar{m}_i/[2-(1-d_1)^{r_i}]}$$

where $d_1 = 1 - \hat{S}^{1/r}$,

$$\hat{S} = \frac{2m_{XY}}{m_X + m_Y},$$

i refers to the ith type of enzyme (in this case there are two types, 4-base and 6-base enzymes),

$$\bar{m} = (m_X + m_Y)/2$$

and where the standard error of d is

$$s_d = \left(\frac{1}{\sum_i \frac{2r_i^2 \bar{m}_i S_i}{(2-S_i)(1-S_i)}} \right)^{1/2}$$

where

$$S_i = e^{-r_i d}$$

where d is the estimated fraction of nucleotides at which X and Y differ; r, the number of base pairs recognized by a given restriction enzyme (in this case, 6 or 4); m_X and m_Y, the number of restriction sites on, respectively, the X and Y chromosomes; m_{XY}, the number of restriction sites shared by the X and Y chromosomes. Note that the polymorphic *Taq*I site on the X chromosome contributes 0.5 to the value of m_X for *Taq*I.

~22 kb at *DXYS1*, nine are common to the X and Y chromosomes, one is specific to the Y chromosome, and one is specific to the X chromosome. Thus, of at least 12 *Mbo*I sites represented by these fragments, one site is specific to the Y (Fig. 2*a*), and all other sites are common to the X and Y chromosomes. The results of several hybridization experiments that revealed restriction sites specific to either the X or the Y chromosome are shown in Fig. 2*b*.

Sequence divergence

The fraction of nucleotides at which a pair of homologous DNAs differ can be estimated by comparing the restriction maps of the two sequences. Given the comparative X–Y restriction map of *DXYS1* (Fig. 2*a*), we set out to determine the fraction of nucleotides at which the X and Y chromosomes differ in this region. This fraction was estimated using the iterative 'nucleotide counting' method of Nei and Tajima[15]. In using this method, we assume that restriction cleavage sites are created or eliminated solely by substitutions of base pairs. The calculation involves only those mapped restriction sites which fall within the 21 kb at *DXYS1* which we have cloned, and which is mapped in its entirety for seven enzymes (Fig. 2*a*). The data on *Mbo*I fragments are not included in the calculation as they do not represent mapped sites. Drawing on data for the seven other enzymes, we estimate that the human X and Y chromosomes differ at 0.83 ± 0.54% of their nucleotides at *DXYS1* (Table 1). It has been argued that CpG nucleotide dimers (such as occur within the recognition sequences of the enzymes *Taq*I and *Msp*I) are remarkably prone to mutation in humans[16]. If the *Taq*I and *Msp*I data are eliminated from the calculation of X–Y sequence divergence, the estimate of that divergence falls to 0.37 ± 0.38%.

Homologous sequences in great apes

Our estimate of X–Y sequence divergence at *DXYS1* (0.37 ± 0.38%) is lower than estimates of the divergence of the human and chimpanzee genomes as a whole (1–3%)[17–20]. Assuming that the X and Y chromosomes do not evolve more slowly than the autosomes, this suggests one of two possibilities. First, *DXYS1* could represent an evolutionarily ancient homology between the X and Y chromosomes and some mechanism could retard or repair X–Y divergence at that locus. Alternatively, the presence of *DXYS1* sequences on both the X and Y chromosomes might be a phenomenon limited to recent evolutionary times. According to this hypothesis, *DXYS1* sequences have been present on both the X and Y chromosomes only for a period comparable to or shorter than that since humans diverged from chimpanzees.

To distinguish between the two possibilities, genomic DNAs from the great apes were examined for sequences homologous to *DXYS1*. If *DXYS1* represents an ancient homology between the X and Y chromosomes, one would expect to find *DXYS1*-homologous sequences on both the X and Y chromosomes in all the great apes. However, if X–Y homology at *DXYS1* is of recent origin, one would expect to find *DXYS1*-homologous sequences on either the X or Y chromosome, but not on both.

Filter hybridization experiments revealed that the great apes have *DXYS1*-homologous sequences only on their X chromosomes. Gel transfers of *Eco*RI digests of human and ape DNAs were hybridized with probe 5 (Fig. 2*a*) at moderately high stringency as described in Fig. 2 legend. At least one male and one female of each of three ape species (chimpanzee, gorilla

Table 2 Dosage of *DXYS1*-homologous sequences in male and female ape DNAs

	Sex	Autosomal standard: Ratio of areas *DXYS1*/β-globin	X-linked standard: Ratio of areas *DXYS1*/*DXS9*	No. of *DXYS1* copies per cell
Chimpanzee	M	0.30 (0.5)	0.83 (0.9)	1
	M	0.33 (0.6)	0.88 (1.0)	1
	F	0.59 (1.0*)	0.92 (1.0*)	2
	F	0.60 (1.0)	0.89 (1.0)	2
Gorilla	M	0.36 (0.6)	1.06 (1.1)	1
	F	0.62 (1.0*)	0.96 (1.0*)	2
	F	0.75 (1.2)	0.97 (1.0)	2
Orangutan	M	—	1.17 (1.2)	1
	F	—	1.00 (1.0*)	2
Human	M	0.60 (1.1)	1.95 (2.4)	2
	F	0.55 (1.0*)	0.83 (1.0*)	2

Genomic human, chimpanzee, gorilla and orangutan DNAS were digested with *Eco*RI, blotted and hybridized with probes for *DXYS1* and β-globin or *DXYS1* and *DXS9* (RC8, ref. 21) as described in Fig. 3 legend. To ensure a linear relationship of filter-bound radioactivity to absorbance on the autoradiogram, no intensifying screen was used. As in Fig. 3*b*, densitometric scans of the autoradiograms were made. The areas under the peaks corresponding to *DXYS1* and β-globin or *DXYS1* and *DXS9* were integrated, and, for each species, the ratios of these areas were normalized to the female, indicated by an asterisk. (*DXYS1*/β-globin ratios could not be calculated for the orangutans because of poor separation of the *DXYS1* and β-globin peaks.) The number of copies of *DXYS1* per cell was calculated assuming that females have two copies per cell of both β-globin and *DXS9* and that males have two copies per cell of β-globin and one of *DXS9*.

and orangutan) were examined. In humans, probe 5 detects a 4.5-kb *Eco*RI fragment that is common to the X and Y chromosomes. Thus there are two copies per cell in both males and females. All ape DNAs contained sequences homologous to *DXYS1* (for example, Fig. 3*a*). In the gorilla and chimpanzee, probe 5 detects a 4.5-kb *Eco*RI fragment, and in the orangutan, probe 5 detects two *Eco*RI fragments of 3.4 and 5.3 kb. Unlike the human, however, in all three ape species the dosage of *DXYS1*-homologous sequences is a function of sex. As judged using an autosomal (β-globin) or X-linked (*DXS9*, probe RC8; ref. 21) reference standard, in each of the three ape species, females contain twice as many copies of the *DXYS1*-homologous sequence as do males (Table 2, Fig. 3); no male-specific *Eco*RI (or *Taq*I, data not shown) fragment was found in any of the apes. The most economical interpretation of these findings is that *DXYS*1-homologous sequences occur only on the X chromosome among the great apes. Thus, it seems that X–Y homology at *DXYS1* is of recent origin and, among extant species, is found only in man.

Conclusions

Homology of single-copy DNA sequences on mammalian X and Y chromosomes was first reported at the human locus *DXYS1* (ref. 9), and there is now increasing evidence of substantial homology of single-copy sequences of no known function on the human X and Y chromosomes[22]. However, although a monoclonal antibody elicited by an antigen (12E7) encoded by the human X chromosome cross-reacts with an antigen coded for by the human Y chromosome[23], there is little rigorous evidence of homologous functional genes on the X and Y chromosomes of any mammal.

Our mapping of *DXYS1* to Xq13–q21 is consistent with the findings of other workers. J. Weissenbach (personal communication) has, by means of a different panel of rodent–human cell hybrids containing portions of the human X chromosome, assigned *DXYS1* to Xq12–q22. Drayna *et al.*[24] have recently demonstrated a genetic distance of about 12 centimorgans between *DXYS1* and *DXS17* (S21), which in turn has been mapped to Xq21–q22.

The findings reported here are not consistent with a model that limits X–Y sequence homology to the short arms of the X and Y chromosomes. Terminal portions of the short arms of the X and Y chromosomes pair during meiosis in human spermatogenesis[3–7], and this observation provided the basis for the prevailing model of homology between the human X and Y chromosomes[1,8]. According to this hypothesis, the terminal, pairing portions of the X and Y chromosomes are homologous at the DNA sequence level, while the non-pairing, or 'differential', portions are not. However, we have demonstrated the presence of single-copy DNA sequences (*DXYS1*) homologous to the Y chromosome at Xq13–q21, far outside the pairing region of the X chromosome. In addition, there seem to be numerous other single- or low-copy number[22] and repetitive[25] sequences on Xq which are homologous to the Y chromosome. Thus, although single-copy sequence homology between Xp and Yp may exist, X-Y homologous sequences are clearly not limited to those regions. Furthermore, *DXYS1* sequences on the short arm of the Y chromosome, virtually all of which is thought to pair with the X (ref. 26), have no homologue on the short arm of the X. Thus, although the pairing regions of the X and Y chromosomes may be partially homologous, it is unlikely that there is continuous X–Y homology throughout the length of the pairing region.

We have previously reported[9] our failure to observe meiotic recombination between the X and Y chromosomes at *DXYS*1. Given the location of *DXYS1* at Xq13–q21, it is now clear that single reciprocal cross-overs between the X and Y at *DXYS1* would destroy the integrity of both the X and Y chromosomes.

It is widely accepted that the mammalian X and Y chromosomes evolved from a completely homologous pair[2]. It has been assumed, as a corollary, that if limited homology of the human X and Y chromosomes exists, the homology should be ancient in an evolutionary sense[1]. The findings reported here demonstrate that this need not be the case. Among extant species, *DXYS1*-homologous sequences apparently occur on both the X and Y chromosomes only in man; in chimpanzee, gorilla and orangutan, *DXYS1*-homologous sequences are found only on the X chromosome. Thus, the simplest explanation is that *DXYS1*-homologous sequences were transposed from the X chromosome to the Y chromosome after the human line diverged. (To argue that the common ancestor of all four species had *DXYS1*-homologous sequences on both X and Y chromosomes, one must appeal to the loss of *DXYS1*-homologous sequences from the Y chromosome three times during evolution.) This hypothesis is consistent with the finding that the divergence of human X and Y DNA sequences at *DXYS1* is somewhat less than the divergence of the human genome from that of its closest relative, the chimpanzee. It is estimated that the human and chimpanzee lines diverged between 4 and 8 Myr ago[20,27,28]. Thus, *DXYS1* sequences have been present on both the X and Y chromosomes for less than—perhaps much less than—8 Myr.

The full extent of the X-to-Y transposition that occurred at *DXYS1* during human evolution is unknown, but it is clear that at least 36 kb of DNA was involved. To our knowledge, this X-to-Y transposition has not been detected by comparative light microscopic examination of banded human and ape chromosomes[29]. The recent finding[22,25] of other human X–Y homologous sequences on Xq suggests either that the transposition was much larger than 36 kb or that it was in some way directed by preexisting X–Y homologies.

We thank Tom Mañiatis for a human genomic DNA library; Kay Davies for a human X chromosome library and for phage RC8; Gail Bruns for cell hybrid DNAs; Kirby Smith for ape and human DNAs; Lou Kunkel for human DNAs; Stu Orkin for plasmid πSVβ; and Arlene Wyman and Linda Wolfe for preparing some of the human DNAs and Southern blots. We particularly thank Masatoshi Nei for assistance with the calculations of nucleotide divergence, and we appreciate the advice of Luca Cavalli-Sforza. We thank Connie Holm, Arlene Wyman and Linda Wolfe for useful criticisms of the manuscript. This work was aided by grants from the NIH (to D.B., Arlene Wyman and Melvin Simon) and from the Wills Foundation (to Arlene Wyman). D.C.P. received research stipends from Harvard Medical School, and M.E.H. received a NIH National Research Service Award.

Correlation between segmental mobility and the location of antigenic determinants in proteins

Most continuous antigenic determinants of tobacco mosaic virus protein (TMVP), myoglobin and lysozyme correspond to those surface regions in the protein structure, as determined by X-ray crystallography, which possess a run of high-temperature factors along the polypeptide backbone, that is, a high segmental mobility. The mobility of an antigenic determinant may make it easier to adjust to a pre-existing antibody site not fashioned to fit the exact geometry of a protein. The correlation found between temperature factors and antigenicity is better than that between hydrophilicity and antigenicity.

THE antigenic reactivity of proteins resides in restricted parts of the molecule known as antigenic determinants or epitopes. Antigenic determinants represent the accessible patches on the surface of a native protein that interact with the binding sites of antibody molecules. Epitopes made up of a continuous sequence of amino acid residues are called 'continuous determinants' while 'discontinuous determinants' consist of residues that are not contiguous in the primary structure but which are brought together by the folding of the polypeptide chain[1]. The continuous epitopes comprise five to eight residues and their uniform size in different proteins reflects the constant size of the complementary antibody combining sites.

The localization of continuous determinants in proteins is based on measurements of the antigenic reactivity of natural or synthetic peptides of the molecule[2,3]. Usually, the fragments are tested for their ability to inhibit the reaction between antibodies and the whole antigen, and very high molar ratios of peptide to intact antigen are often required to achieve significant inhibition; this is usually explained by assuming that peptides exist in solution in a variety of random conformations and that only the rare conformations which approximate to that found in the native protein will bind to the antibody[4,5]. Both the N- and C-termini of different proteins often show higher than average antigenic activity[6–14], presumably because they are located at the surface and have a high relative flexibility[15].

In the last few years, the importance of the internal dynamics of protein molecules in relation to function has been emphasized[16–18]. This appreciation prompted us to examine whether there is a more general link between the local mobility of short segments of proteins and the antigenic structure. For this study we selected three proteins: the coat protein of tobacco mosaic virus (TMVP), myoglobin and lysozyme, which have been studied extensively by X-ray crystallography[19–21]. Present refinement methods[22,23] give not only precise atomic coordinates but also atomic temperature factors (B values). The temperature factor represents the mean-square displacement of each atom and, when plotted against residue number, provides a graphic image of the degree of mobility existing along the polypeptide chain. Such plots were used to examine the possible correlation between the mobile segments of these proteins and the locations of their epitopes.

Tobacco mosaic virus protein

The antigenic properties of the coat protein of tobacco mosaic virus have been extensively studied by several groups[24]. Milton and Van Regenmortel[25] originally reported that TMVP possesses five continuous antigenic determinants situated in tryptic peptides I, IV, VIII and XII. Peptide I contains two epitopes located in residues 1–10 and 34–39. The epitope in peptide VIII has been studied extensively by Benjamini[26], who located it in residues 105–112, although some residual activity is also found in the shorter pentapeptide, 108–112. Two additional antigenic determinants were recently identified[10] in residues 55–61 and 80–90, by comparing the inhibitory activity of tryptic peptides II, III (42–61) and VI (72–90) from three strains of the virus. Three peptides corresponding to residues 72–77, 129–134 and 142–147 that were synthesized because they correspond to accessible regions on the surface of the TMVP molecule were found to have no significant (that is, above the 10% level) antigenic activity in enzyme-linked immunosorbent assay (ELISA) inhibition tests.

Thus, the many studies of the antigenic structure of TMV[10,26,27] have so far revealed only seven continuous epitopes in the protein. The immunoassays were carried out at very low

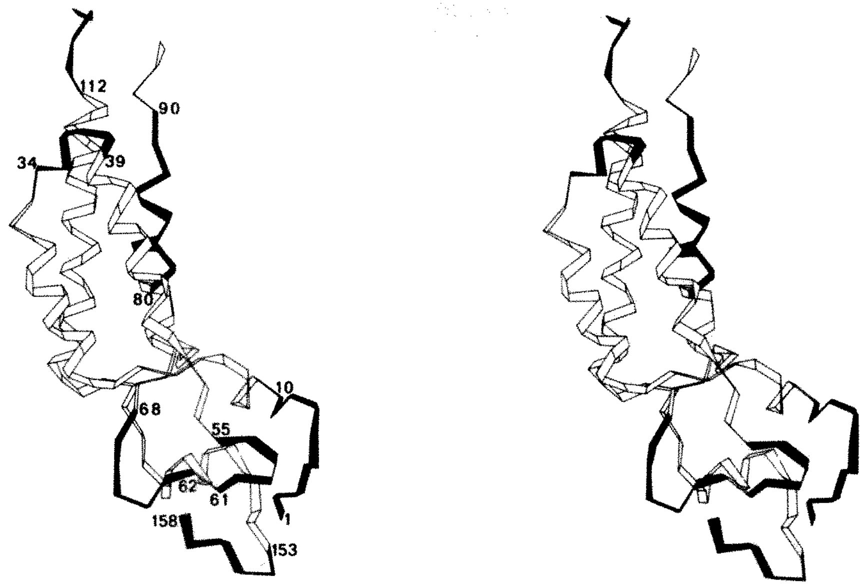

Fig. 1 Stereo drawing of the α-carbon backbone of the TMVP subunit at the present stage of refinement of the protein disk (A-ring). All residues (1–158) are shown except for 94–106, which are omitted because this region of the polypeptide has no specific conformation in the disk. The locations of the seven continuous antigenic determinants are indicated by solid lines.

concentrations where the protein is almost totally dissociated into monomers. The presence of very small amounts of other species would, in any case, not influence the measured degree of inhibition.

The seven epitopes are situated in the vicinity of residues 1–10, 34–39, 55–61, 62–68, 80–90, 105–112 and 153–158. Their positions in the TMVP molecule are shown in Fig. 1. The starting model of the TMVP subunit as seen in the protein disk at 2.8 Å resolution[19] has been subjected to constrained crystallographic refinement[22] to produce these coordinates and temperature factors (A.M. and A.C.B., in preparation). When the positions of the epitopes of TMVP were superimposed on a plot of the temperature factors of main-chain atoms in each residue (Fig. 2), it was found that all seven antigenic regions correspond to local maxima of the *B* value. Furthermore, the positions of six of the seven epitopes correlate with the major peaks, whereas only one epitope corresponds to a minor peak (residues 55–61); the lack of mobility in this seventh epitope can perhaps be explained by the fact that, in the crystal, residues 55–61 are constrained, in both layers of the TMV protein disk, by strong intermolecular contacts involving hydrogen bonding, hence they show a lower *B* value than would occur in an isolated monomer. A similar plot of the overall temperature factor for each residue (thus including the side-chain atoms) displays additional peaks which do not correspond to observed antigenic determinants. Thus, side-chain mobility does not correlate with antigenicity whereas that in the main chain does.

It is well known that the N- and C-termini of many proteins are flexible and accessible on the molecular surface[15]. In several cases (reviewed in 28, 29) the termini are known to be antigenic determinants (for example, the carboxy-terminal of histone H3 (ref. 9), TMVP[10], simian virus 40 T-antigen[30]). However, we did not expect that all the other known epitopes of TMVP would also belong to regions having higher than average flexibility. The three antigenically inactive peptides (residues 72–77, 129–134 and 142–147) lie in surface regions but do not have *B* values significantly different from the mean. This last finding shows that the correlation in Fig. 2 is not based solely on the high surface accessibility of these regions.

The locations of the seven TMVP epitopes were also superimposed on a plot (Fig. 3) of the hydrophilicity values of the protein residues calculated according to Hopp and Woods[31,32]. These plots have been used to predict positions of epitopes in proteins for which only the sequence is known[32–34]; their predictive value stems from the fact that hydrophilic residues lie predominantly at the surface and are therefore more likely to belong to epitopes. Although Fig. 3 shows a good correlation between antigenicity and some of the hydrophilicity peaks (for example, residues 62–68), several of the maxima correspond to regions with no proven antigenic activity, and the agreement with hydrophilicity is thus less striking than that with *B* values.

Myoglobin

The antigenic structure of myoglobin has been studied extensively by Atassi and collaborators[35], who identified five epitopes in residues 15–22, 56–62, 94–99, 113–119 and 145–151. Although it was claimed that these five sequences accounted for all the antigenic properties of myoglobin[36], subsequent work showed that additional continuous epitopes are present in regions 1–6, 22–55, 72–89 and 121–127 (refs 37–40).

The temperature factors plotted in Fig. 4*a* are taken from the restrained least-squares refinement[22] of oxymyoglobin at 1.6 Å resolution[20] using diffraction data collected at −12 °C. The *B* values are, in general, low in helical regions and high at bends and chain termini, but it is clear that in myoglobin the deviations from the mean are small[20] and few distinctive peaks are present (Fig. 4*a*). This observation is related to the high helix content and compact nature of the protein, which has no long flexible

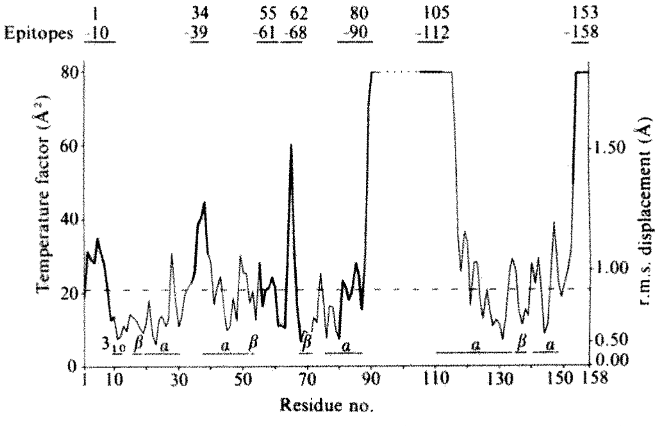

Fig. 2 The mean temperature factor of the main-chain atoms in each residue plotted against residue number for the TMVP disk. These temperature factors are from the constrained crystallographic refinement[22] of the disk of TMVP at 2.8 Å resolution. Strict 17-fold non-crystallographic symmetry constraints were applied throughout the refinement. Temperature factors for the A-ring are shown here although those for the B-ring are esentially the same (A.M. and A.C.B., in preparation). The mean value of the temperature factor (omitting residues for which $B > 80$) is shown by a dashed line. The locations of the seven continuous antigenic determinants are indicated by thick lines. Regions of secondary structure are denoted α, β, 3_{10}. The r.m.s. value of the displacement is calculated from $\overline{U^2} = \overline{U_x^2} + \overline{U_y^2} + \overline{U_z^2} = 3B/8\pi^2$, where U is the total displacement and U_x, U_y, U_z are the components.

loops. The positions of six of the nine epitopes correlate with local maxima; however, one epitope (residues 56–62 at the tight corner between helices D and E) corresponds to a minimum. No conclusion can be made about the epitopes in peptides 22–55 and 72–89 (ref. 40) because of the uncertainty in their location.

Lysozyme

The antigenic structure of lysozyme has been studied by Atassi and colleagues[41] who identified three discontinuous epitopes centred around the disulphide bridges 30–115, 76–94 and 6–127. It was claimed that these three epitopes account for all the antigenicity of lysozyme[42], although other investigators have shown that the loop formed by the residues lying between the disulphide bridge at 64–80 (refs 43–46) and also residues 38–54 possess antigenic activity[47]. The antigenic reactivity of the loop depends on the preservation of the disulphide bridge.

Figure 4*b* shows the variation of the temperature factor along the polypeptide chain of lysozyme[21]. The mean main-chain temperature factors are from the restrained least-squares refinement[23] of the tetragonal hen egg white lysozyme (HEWL) at 2 Å resolution. Three peaks are seen in Fig. 4*b* around residues 47, 70 and 101. The peaks at 47 and 70 correlate with the known epitopes, but are not found in a corresponding plot for the orthorhombic form of HEWL, where these residues are involved in molecular contacts within the crystal[21]. The third peak, 99–102 (which corresponds to one tip of the active site), is found in both forms of HEWL[21] and also in human lysozyme[20]. No antigenic activity has been reported to involve these residues, but there is a discontinuous epitope nearby on the sides of the active site cleft, which, as noted by Artymiuk *et al.*[18], lies in a region of relatively high flexibility. We have isolated, by HPLC, a tryptic peptide that encompasses the region 99–102, but found that it possessed no antigenic reactivity in ELISA inhibition tests[11].

Conformational dependence of epitopes

Several opposing views of the nature of protein epitopes have emerged recently[48]. In one picture, proteins contain only a small number of discrete antigenic regions situated in highly accessible surface locations[36,42]. The presence of antigenic reactivity when these parts are excised from the intact molecule is then ascribed to the preservation of specific conformational features. That the antigenic reactivity of proteins is dependent on the native conformation is corroborated by the finding that there is usually very little cross-reactivity between the native and denatured forms of the molecule.

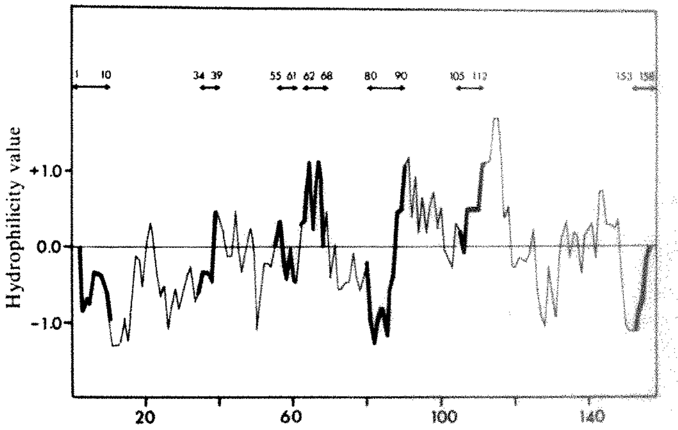

Fig. 3 The hydrophilicity value of each residue of TMVP (calculated after Hopp and Woods[31]) plotted against residue number, after averaging the value over six residues. The locations of the seven continuous epitopes are indicated by thick lines.

From studies of the immunological cross-reactivity between related proteins, a contrasting view has emerged—that virtually the entire accessible surface of a protein can combine with appropriate antibodies[49,50]. Consequently a considerable proportion of the antigenic determinants of globular proteins must be discontinuous in character as only a small part of the surface of a globular protein is made up of linear arrays of residues[40,48]. Indeed, attempts to locate protein epitopes by using monoclonal antibodies directed against the native molecule have led to the identification of mainly discontinuous epitopes[51–54]. It seems that as monoclonal antibodies recognize a small sample of all antigenic specificities, they are more likely to be directed against the numerous surface patches of a protein made up of residues distant in the sequence, rather than against continuous determinants.

Clearly, discontinuous epitopes cannot be studied with antibodies specific for short linear peptides and cannot be identified in linear plots of flexibility along the protein chain. Although the correlation we have demonstrated between segmental mobility and the location of epitopes pertains only to continuous epitopes, the notion of flexibility in epitopes is of considerable interest in the current debate on what constitutes an antigenic determinant.

The classical method of localizing epitopes by measuring the antigenic reactivity of cleaved fragments of the protein with anti-protein antibodies is now being increasingly replaced by an analysis of the specificity of antibodies raised against various fragments. It was originally believed that antibodies reactive with the native protein would be produced only if the fragment used for immunization closely reproduced the tertiary conformation of the protein. However, recent work shows that many

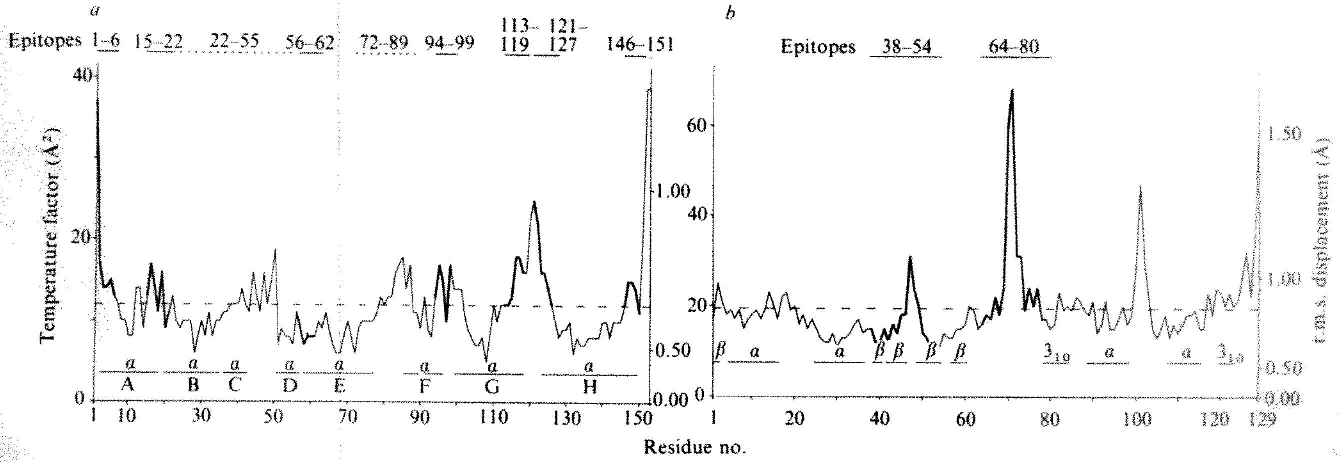

Fig. 4 The mean temperature factor of main-chain atoms plotted against residue number for: *a*, oxymyoglobin (redrawn after ref. 20) and *b*, lysozyme (redrawn after ref. 21). The mean temperature factor is shown by a dashed line. The first and last residue numbers are given for each continuous epitope and the mean displacement is calculated from $\overline{U^2} = 3B/8\pi^2$.

linear synthetic peptides corresponding to parts of proteins are able to elicit antibodies that react with the intact antigen[28–30,33,55]. One explanation is that synthetic peptides are able to mimic the corresponding regions of the native protein because one of the conformations adopted in solution approximates that in the native molecule[33]. In the so-called stochastic model, this native-like conformation of the peptide is assumed to be rare. An attempt to test this model involved estimating the frequency with which monoclonal antibodies directed against peptides recognize the corresponding intact protein[56]; of 21 hybridomas that synthesized antibody against an influenza haemagglutinin peptide, 16 produced antibodies that reacted with the complete molecule. Such a high frequency seems to refute the view that the immunogenic form of the peptide corresponds to a rare conformational occurrence. However, the results described for haemagglutinin are rather unusual, as conventional antibodies raised against the complete molecule did not react with any of 20 peptides representing nearly the entire sequence of the molecule[55]. Furthermore, it is also possible that the anti-peptide monoclonal antibodies recognized the intact haemagglutinin because this molecule had been partly denatured by the immunoassay procedures used in the experiments. It seems, therefore, that the stochastic model has not yet been adequately tested.

There is also an apparent contradiction between the finding that, on the one hand, monoclonal antibodies raised against a native protein are so conformation-specific that they usually do not bind to peptide fragments of the molecule, while, on the other hand, the majority of monoclonal antibodies raised against a peptide fragment also recognize the intact molecule[48,54,56]. This contradiction might disappear if truly native, that is, correctly folded, intact, molecules were tested for their ability to react with anti-peptide monoclonal antibodies.

The obverse explanation offered for the finding that anti-peptide antibodies specific for different conformations of the peptide bind to the complete molecule is that local disorder in short segments of the protein mimics the flexibility of the peptide in solution[56]. The data shown in Figs 2 and 4 represent the first concrete evidence of a link between high local mobility in proteins and the location of (continuous) antigenic determinants, but it should be stressed that this motion is generally one about a well-determined average conformation, even though the r.m.s. displacements in the cases of TMVP and lysozyme are of the order of 1–1.5 Å (Figs 2, 4*b*). The mobility in the epitope may make it easier to adjust to an antibody site which after all has not been fashioned to fit the exact geometry of a particular protein. It may be necessary, therefore, to discard one of the assumptions of protein immunochemistry according to which epitopes in intact proteins are conformationally rigid while epitopes in short peptides are highly flexible.

The view that linear peptides in solution necessarily comprise a very large number of conformers, only some of which are recognized by protein-specific antibodies, arose from the finding that large molar excesses (of the order of 10^3–10^4) of peptide over intact protein are needed to reveal their antigenic reactivity[4,5]. However, it is also possible that most antigenically active linear synthetic peptides contribute only a short stretch within them to a larger discontinuous antigenic region, and thus that the low level of antigenicity is not simply due to incorrect folding of the peptide.

Thus, the question remains of explaining the success that has been achieved in raising anti-peptide antibodies that are able to recognize apparently native proteins. It is conceivable that the extremes of segmental motion of proteins of the kind demonstrated here may provide the necessary degree of conformational similarity between the isolated peptide and the same region in the intact molecule. Epitopes located in flexible segments of the protein would be recognized in the form of peptides when the conformational prerequisites for building the antigenic structure are not very stringent—this is the case for the epitopes of TMVP and myoglobin that were identified by measuring the antigenicity (Fig. 2) and/or immunogenicity (Fig. 4*a*) of short peptides by using polyclonal antisera. In general, therefore, antibodies raised against a peptide would have a high probability of recognizing the corresponding epitope in the complete protein, whereas monoclonal antibodies raised against the intact protein would tend to be directed against the discontinuous epitopes which are more numerous[51,52,54].

Although segmental flexibility in proteins emphasizes only one type of antigenic determinant, its understanding is of crucial importance as it is probably on this type of epitope that present hopes for successful synthetic vaccines are ultimately based. Methods for predicting the secondary structure of proteins achieve a better success rate for loops and turns than for helices and sheets[57]. As loops and turns are more likely to correspond to flexible segments of proteins, peptides corresponding to sequences predicted to lie in these positions should be good candidates for synthetic vaccines.

Antibodies to gap-junctional protein selectively disrupt junctional communication in the early amphibian embryo

Anne E. Warner, Sarah C. Guthrie & Norton B. Gilula*

Department of Anatomy & Embryology, University College London, Gower Street, London WC1E 6BT, UK
* Department of Cell Biology, Baylor College of Medicine, Houston, Texas, USA

Antibodies to the major protein of rat liver gap junctions, molecular weight 27,000 (27K), have been microinjected into one identified cell of 8-cell stage Xenopus *embryos. This treatment selectively disrupts both dye transfer and electrical coupling between the progeny cells. These results provide evidence that the 27K protein is an integral component of the cell-to-cell junctional channel. The disruption of junctional communication at early stages results in specific developmental defects, suggesting that blocking intercellular communication can have a pronounced influence on embryonic development.*

CELLS within the embryos of most species are able to communicate directly with each other through a low electrical resistance pathway. This pathway, which probably reflects the presence of the morphological structure, the gap junction[1], has been described in all embryos so far studied, both vertebrate and invertebrate[2]. Communicating junctions are found between embryonic cells, regardless of their eventual developmental fate, at times when other evidence suggests that they are capable of influencing each other. This has led to the suggestion[3] that the direct communication pathway mediated by gap junctions is responsible for the cell-to-cell transfer of information involved in directing embryonic development. Despite widespread support for this view, there is little evidence to indicate that gap junctions play a pivotal role in embryonic development.

There are a number of methods for reducing the permeability of gap junctions: raising intracellular calcium[4], lowering intracellular *p*H (ref. 5) or treatment with alcohols[6]. However, all of these methods elicit secondary metabolic effects, making it difficult to relate unequivocally any effects these agents might have on development with their ability to lower gap-junctional permeability.

In recent years it has become possible to isolate and characterize constituent proteins from isolated gap junction preparations[7,8]. This offers the opportunity to generate gap junction-specific antibodies which may be used to study the physiological properties of gap junctions. Here, we report the results of experiments to test whether antibodies raised against the major gap-junctional protein are able to interfere with cell–cell communication. In addition we have examined the developmental consequences of treatment with such antibodies.

Antibodies

For this analysis, three different affinity-purified rabbit polyclonal antibodies were selected. Polyclonal antibodies were preferred, as monoclonal antibodies are generally highly species-specific and rarely directed against functional portions of the molecule. Two of the antibodies (A and B) were generated by immunizing rabbits with a 27,000 molecular weight (27K) protein, the major protein present in rat liver gap junctions. The 27K protein was electrophoretically eluted from rat liver gap junctions which had been prepared as described in ref. 9. The sera from these two rabbits were purified on an affinity column containing only the eluted 27K protein. The resulting affinity-purified reagents bound specifically to the denatured 27K protein on immunoblots, as well as to 47K and 54K proteins present in homogenates of rat liver (Fig. 1*a* (1–3), *b* (1–3)). The 47K protein represents a 'dimeric' form of the 27K protein[7,8], while the relationship between the 54K and the 27K proteins in rat liver has not yet been clarified. All three of these molecules are recognized by the antibody that was affinity purified on the 27K column, as absorption with the 27K protein removes staining of the 47K and 54K bands. In addition, the affinity-purified antibodies bind to the cytoplasmic surface of intact rat liver gap junctions as indicated by electron microscopic immunolocalization both on isolated gap junctions and in intact liver. A detailed description of the preparation and characterization of the antibodies will be published elsewhere (N.B.G. *et al.*, in preparation). Immunochemical evidence for the existence of related determinants in *Xenopus* embryos was obtained by applying antibody B to a nitrocellulose blot containing the 27K rat liver gap junction protein, a rat liver homogenate, and homogenates of various stage *Xenopus* embryos (see legend to Fig. 1). The immunoblot in Fig. 1 provides direct evidence that antigenically related proteins, comparable in size to those found in rat liver, are present in unfertilized *Xenopus* eggs and embryos. The 54K molecule, present in homogenates of both rat liver and *Xenopus* embryos, is the most abundant antigenic species that has been detected in immunoblots of *Xenopus* homogenates (unfertilized eggs, fertilized eggs, 8-cell, and 32-cell embryos). As noted earlier, the relationship between the 27K protein and the 54K antigenic species has yet to be clarified both in rat liver and in *Xenopus*. The 54K protein could represent a biosynthetic precursor of the gap junction, as indicated by Epstein *et al.*[10] on the basis of the speed with which junctions can form between communication competent cells, and the ability to form junctions in the prolonged absence of protein synthesis and ATP production. Alternatively, the 54K protein may represent the undegraded gap-junctional protein as elimination of endogenous protease activity when preparing plasma membranes is very difficult. However, this uncertainty does not invalidate conclusions about the ability of the antibody raised against gap junctional protein to interfere with cell to cell communication, which are drawn from the results given below. The third antibody (C) was generated against, and specifically interacted with, an extracellular matrix glycoprotein that is synthesized and secreted by rat liver and *Xenopus* embryos. There was no cross-reactivity between this antibody and any of the species recognized by the antibody raised against gap junction protein, or with gap junctions. Conversely, the gap-junction antibody does not recognize the extracellular matrix glycoprotein. The 54K protein recognized by the gap junctional antibody cannot, therefore, be a contaminant from the extracellular matrix glycoprotein. Antibody C was therefore used as a control antibody that did not interact with gap junctions or the 27K gap-junctional protein.

The presence of gap-junctional proteins in the unfertilized egg may seem surprising. However, in the early *Xenopus* embryo, zygotic RNA and protein synthesis does not begin until the 'midblastula transition' (ref. 11). All material necessary for progression through development to the blastula stage must, therefore, be available in the unfertilized egg. This would include the production of gap junctions, as well as many other cellular products. For example, it has been reported that fibronectin is present in early *Xenopus* embryos 2 h after fertilization and subsequently as a product of maternal transcripts[12], and large quantities of sodium are sequestered in the egg for subsequent transfer to the blastocoel fluid as the blastocoel cavity forms[13].

To test whether these antibodies were capable of interfering with intercellular communication, they were injected into *Xenopus* embryos at the 8-cell stage. The injections were always made into the same cell, located in the region of the grey crescent (Fig. 2*a*). Assays of intercellular transfer were made two cleavage divisions later at the 32-cell stage (Fig. 2*b*), which allowed sufficient time for the antibody to diffuse throughout the four daughter cells. To confirm that the cells contained the injected antibody, a second reagent, fluorescein isothiocyanate, (FITC)-conjugated goat anti-rabbit IgG, was applied directly to the antibody-injected region on frozen sections. The localization of antibody at the edge of the injected region is illustrated in Fig. 3*c*.

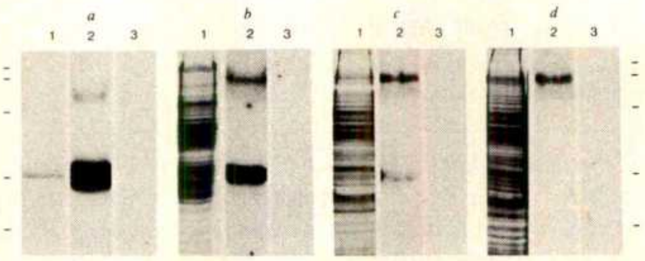

Fig. 1 Immunoblot analysis of rat liver gap-junction protein, rat liver homogenate, and *Xenopus* homogenates with pre-immune and immune affinity-purified antibody B. Lanes *a* (1–3) contained electrophoretically eluted rat liver 27K gap-junction protein, *b* (1–3) contained a protein homogenate from rat liver, *c* (1–3) contained a protein homogenate from *Xenopus* unfertilized eggs and *d* (1–3) contained a protein homogenate from 8-cell stage *Xenopus* embryos. The protein in lanes labelled 1 was separated electrophoretically and stained with Coomassie brilliant blue. Samples in all other lanes were transferred to nitrocellulose paper and treated with either the immune antibody B at 1:100 dilution (lanes 2), or with pre-immune antibody B at 1:100 dilution (lanes 3). The bound immunoglobulin was detected with an autoradiogram following treatment with ^{125}I-labelled *Staphylococcus* protein A. Molecular weight standards are indicated by lines to the left and right of the figure; they represent (from top to bottom) 68K (bovine serum albumin), 57.5K (catalase), 43K (ovalbumin), 25.7K (chymotrypsinogen), and 21.5K (soybean trypsin inhibitor). Note that the 27K junction protein was detected in both the Coomassie blue stained material (lane *a*, 1) and the autoradiograms of the immune antibody-treated material from the eluted 27K protein (*a*, 2), the liver homogenate (*b*, 2), and *Xenopus* unfertilized eggs (*c*, 2). The dimeric form of the 27K protein was readily detected in the eluted 27K preparation (*a*, 2), and minor amounts were detected in the other samples (*b*-*d*, 2). With the same reagent, a slightly larger molecule (about 54K) was detected in rat liver homogenates (lane *b*, 2). The 54K protein was also observed in *Xenopus*, and it was the most abundant antigenic species detected (lanes 2, *b*, *d*). No antigens were detected in any of the samples by the pre-immune reagents, lanes 3.

Methods: The *Xenopus* samples were prepared by collecting at appropriate stages (unfertilized eggs, fertilized eggs, 8-cell stage, and 32-cell stage), removing the vitelline membranes and jelly by dissection, and homogenizing material in 1 mM $NaHCO_3$ with a loose-fitting Dounce homogenizer. The homogenate was spun at 500*g* for 10 min in a Beckman TJ-6 centrifuge to remove most the yolk and pigment granules. The remaining supernatant was spun at 12,900*g* for 15 min in an Eppendorf centrifuge. Both pellets and supernatants from these samples were analysed immunochemically and found to contain immunoreactive material. The samples in this figure represent the 12,900*g* supernatants from the specimens of unfertilized eggs and 8-cell stage embryos. The different protein samples were solubilized in a SDS sample buffer[22] and electrophoretically separated with a 12.5% SDS-polyacrylamide slab gel. The gel was stained with Coomassie blue (2.5% Coomassie blue (w/v), 50% methanol, 7% glacial acetic acid) for about 15–20 min and then destained (40% methanol, 7% glacial acetic acid). For immunoblotting, the protein was electrophoretically transferred from the gel to nitrocellulose paper (BA85; Schleicher and Schuell) according to the published procedure[23]. The paper was initially 'blocked' by treatment with 3% bovine serum albumin (BSA) in Tris buffered saline (TBS) overnight at 4 °C, and then the appropriate antibody was added at a 1:100 dilution in 3% BSA–TBS for 2 h at room temperature. Following several washes in TBS containing 0.1% Nonidet P-40 (NP40), the blot was incubated for 1 h at room temperature with ^{125}I-labelled *Staphylococcus* protein A (ICN) (35 Ci g^{-1} protein). The blot was then washed with TBS–NP40, then TBS alone, dried, and placed on Kodak XAR film with an intensifying screen at −70 °C. The film was exposed for 3 days.

Transfer of Lucifer yellow

The pattern of cell–cell transfer of Lucifer yellow in the 32-cell *Xenopus* embryo is described elsewhere in this issue[14]. In the present experiments, injection of Lucifer yellow were made into one of the cells showing widespread transfer of dye to its lateral neighbours, cell *d* (see Fig. 2*b*), which is one of the progeny of the antibody injected cell. Following injection of either gap-junctional antibody A or B, cell *d* rarely transferred dye to its neighbours. Figure 3*b* is a photograph of an intact embryo after injection of Lucifer yellow into cell *d* of an embryo previously injected with antibody B. The adjacent frozen section (Fig. 3*a*) confirms that the Lucifer yellow remains confined to the injected cell. For comparison, a frozen section taken through an embryo initially injected with pre-immune serum B is shown in Fig. 3*d*, demonstrating extensive transfer of Lucifer yellow to its lateral neighbours. The results of all assays of Lucifer yellow transfer in this series of experiments are shown in Table 1. None of the injected reagents influenced cell membrane potential or cell division. In each set of control embryos, failure to transfer to one or more cells, other than the sister of the previous cleavage, was only observed in about 30% of the embryos tested. In contrast, between 70 and 80% of the embryos injected with antibody A or B failed to transfer dye; transfer failed to take place into cells lying on both sides of the injected cell (see Fig. 3*a*). This implies that the antibodies can block, or reduce, the permeability both of junctions formed before antibody injection, that is, those present at the 8-cell stage, and possibly of junctions formed during the subsequent cleavage to 16 cells. It is also possible that the antibody can inhibit the formation of junctions in later cleavage stages.

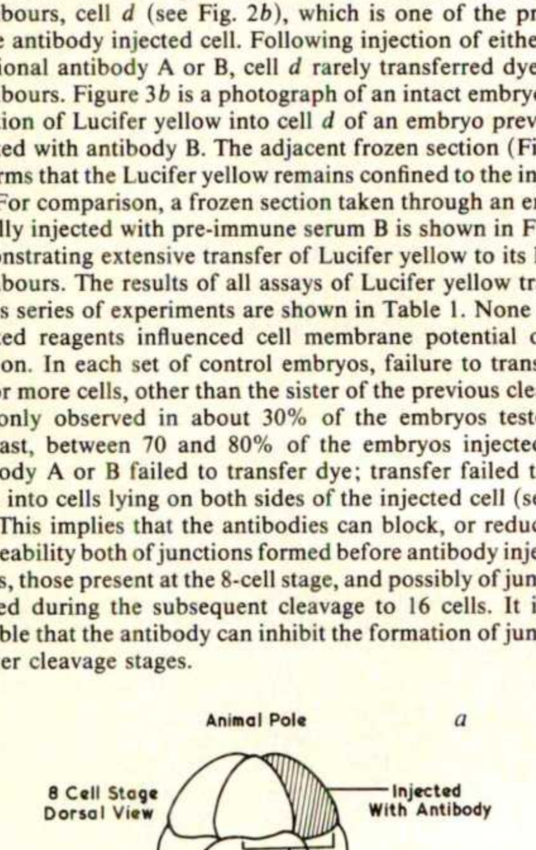

Fig. 2 The location of the cell injected with antibody at the 8-cell stage (*a*) and subsequently with Lucifer yellow, cell *d* (*b*). Hatched region indicates the presence of injected antibody. Cross-hatched region the presence of injected Lucifer yellow. ~15 nl antibody was pressure-injected using a Picospritzer. Lucifer yellow was injected ionophoretically at a current of 100 nA for 5 min with 30 s pulses at 10 Hz. Transfer of Lucifer yellow was assayed at the end of the injection period.

Table 1 Incidence of dye passage in 32-cell stage *Xenopus* embryos after injection of gap-junction antibodies

Condition	Transfer to more than one cell, excluding sister % (n)*	No transfer, or to sister cell only % (n)
Control 1	69 (11)	31 (5)
Control 2	63 (10)	38 (6)
Control 3	79 (11)	21 (3)
Pre-immune A	86 (12)	14 (2)
Pre-immune B	75 (12)	25 (4)
Immune A (I+II)	26 (13)	74 (37)†
Immune B (I+II)	18 (9)	82 (41)†
Immune C (I+II)	76 (40)	34 (21)

Control 1, values taken from ref. 14. Control 2, buffer containing 7.5 mM NaCl, 2.5 mM Na borate, 10 mM boric acid, pH 7.4. Control 3, buffer containing 5 mM Tris, 75 mm KCl, pH 7.6. Pre-immune A, IgG from rabbit A serum obtained prior to immunization injected at 1.5 mg ml^{-1}. Pre-immune B, IgG from rabbit B serum obtained prior to immunization injected at 1.5 mg ml^{-1}. Immune A, affinity-purified IgG from rabbit A after immunization with electrophoretically eluted 27K protein from rat liver gap junctions. Immune B, affinity-purified IgG from rabbit B after immunization with electrophoretically eluted 27K protein from rat liver gap junctions. Immune C, affinity-purified IgG from rabbit C after immunization with electrophoretically eluted glycoprotein from rat liver extracellular matrix. I, reagent affinity-purified X1, injected at a concentration of 1 mg ml^{-1} in buffer 2 or 3. II, reagent affinity purified X2, injected at a concentration of 1.5 mg ml^{-1} in buffer 2 or 3. Results with I and II were identical and were therefore combined in the table.

Methods: All injections were made at the 8-cell stage, in a volume of ~15 nl. Transfer of Lucifer yellow out of cell *d* (for nomenclature see ref. 14) was assessed at the 32-cell stage. Transfer to sister cell only was scored 'no transfer' because of cytoplasmic bridges remaining after cleavage. Transfer was assessed immediately after injection of the dye (5–7 min of injection). The affinity purified reagents were prepared chromatographically[21] using either the 27K protein (antibodies A and B) or the glycoprotein (antibody C) conjugated to CNBr-activated Sepharose 4B (Pharmacia). The sera were applied to the columns and the bound IgG reagents were eluted by treatment with 200 mM glycine, pH 2.6. The reagents were then dialysed against either 0.1 × control buffer 2 or 3, and concentrated 10-fold with a Savant Speed-Vac before use. IgG was obtained from the pre-immune sera by using a Protein A-Sepharose 4B (Pharmacia) column; the bound IgG was eluted by treatment with 100 mM glycine, pH 3.0.

* n = no. of embryos tested.

† Incidence of transfer significantly different from controls (χ^2 test, $P < 0.005$).

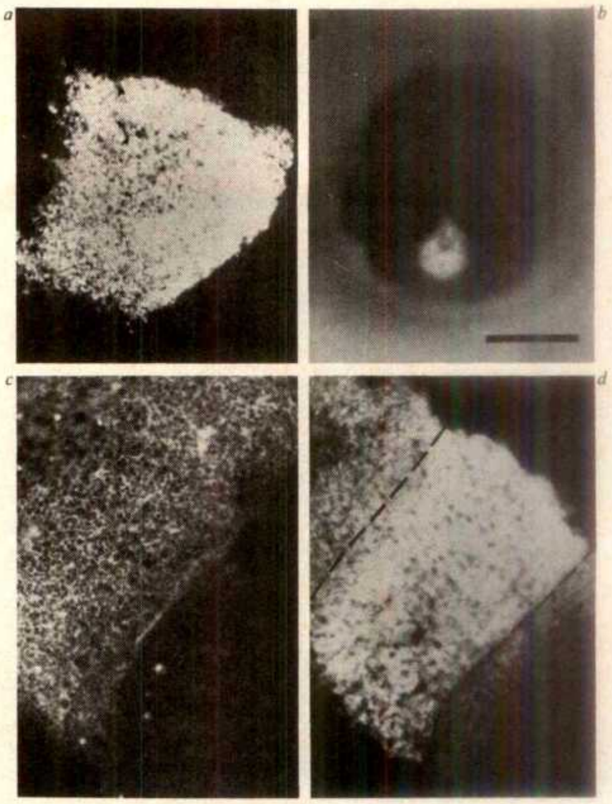

Fig. 3 *a*, Frozen section taken at the 32-cell stage through cell *d* to show restriction of Lucifer yellow to the injected cell after prior injection of antibody B at the 8-cell stage. *b*, Whole embryo injected with antibody B at the 8-cell stage, showing restriction of Lucifer yellow subsequently injected at the 32-cell stage. *c*, Frozen section at the 32-cell stage through embryo injected with antibody B at the 8-cell stage showing antibody stained with FITC-labelled goat anti-rabbit antibody (Nordic Laboratories) applied directly to the frozen section. Note clear restriction of antibody to one of the progeny of the cell injected at the 8-cell stage. *d*, Frozen section through cell injected with Lucifer yellow at the 32-cell stage after injection of pre-immune serum B at the 8-cell stage. Note extensive transfer to both lateral neighbours. Cell borders are indicated by dotted lines. Compare with *a*. Scale bar, 150 μm for *a*; 500 μm for *b*; 100 μm for *c* and 250 μm for *d*. For frozen sectioning, embryos were briefly fixed (1 h) in 4% formaldehyde, frozen in isopentane and 20 μm serial sections were taken on a Bright 5030 cryostat.

To confirm that the antibody was able to block junctions that were already formed, antibody B was injected into cell *d* at the 32-cell stage; this was immediately followed by injection of Lucifer yellow. Subsequent assay for dye transfer took place within 5 min of antibody injection (the minimum time for ionophoretic injection of Lucifer yellow). Of 12 embryos tested, 10 failed to transfer dye. This is significantly less than in control embryos ($0.01 > P > 0.005$). We therefore conclude that the antibody blocks transfer through intact junctions within a short time. It is unlikely that the block is the result of an increase in intracellular calcium, since direct injection of calcium ions will not block gap junctions in *Xenopus*[15]. A fall in intracellular pH ($p\mathrm{H_i}$) is also unlikely, as cell division is inhibited when $p\mathrm{H_i}$ falls sufficiently to block cell–cell communication[5]; cleavage was not affected by injection of antibody. The question of whether the antibody also inhibits the formation of new gap junctions in subsequent developmental stages is more difficult to resolve. This issue must await further experiments designed to analyse the structure of gap junctions in antibody-injected cells several cleavage stages later.

To confirm that these effects were the consequence of the presence of gap-junctional antibody, a number of other controls were carried out. Injection of an antibody to an extracellular matrix glycoprotein (antibody C) had no effect on the transfer pattern (Table 1). Injection of pre-immune sera from the rabbits used to raise antibodies A and B also did not interfere with the pattern of transfer, which was similar to that observed in control embryos (Table 1). Thus only injection of antibodies raised against gap-junctional protein interfered with dye transfer.

Similar experiments were carried out with monovalent fragments of the affinity-purified immunoglobulins, prepared from immune antibody B (refs 16, 17), in order to determine whether the disruption of communication was due to cross-linking of the multivalent IgG on the cytoplasmic surface of the junction, or to a direct interaction of the immunoglobulin with the 27K protein in the channel region. With non-immune Fab fragments (Cappel Laboratories; injected at 1.5 mg ml^{-1}) dye transfer failed in only 20% of the embryos, whereas with the immune fragments (injected at 1.5 mg ml^{-1}) dye transfer failed in 52% of the embryos tested. The incidence of failure to transfer observed after injection of the immune fragments is significantly greater than that observed with the non-immune fragments ($0.1 > P > 0.05$), suggesting that disruption of the channel permeability results from a direct interaction of the antibody with the 27K protein.

Effects on electrical coupling

Dye transfer provides a relatively insensitive measure of cell–cell communication, as low levels of transferred dye may not reach the threshold for detection. To confirm that failure of dye

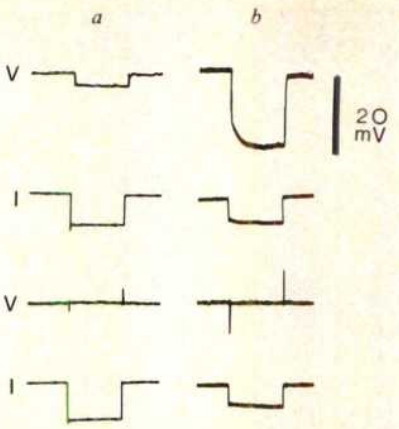

Fig. 4 Electrical coupling between cells injected with either antibody A (*a*) or antibody B (*b*). Embryos were released from the vitelline membrane and the seal between the blastocoel and extracellular fluid mechanically broken to prevent current flow through the extracellular space. One electrode injected hyperpolarizing current pulses (1 s long, 1×10^{-8} A in *a* and 3×10^{-8} A in *b*; current was recorded at different gains in *a* and *b*) into one cell while a second electrode inserted into a lateral neighbour recorded the resultant voltage deflection. Current and voltage recorded using conventional electrophysiological techniques and displayed on an oscilloscope and Gould-Brush pen recorder. Upper pairs of traces show electrical coupling between two cells in the uninjected region. Lower pairs show the absence of electrical coupling in the antibody containing region of each embryo; in both cases only capacitative artefact remains on the voltage trace. Membrane potential was −40 mV (*a*) or −30 mV (*b*). Membrane potentials in the injected and uninjected regions were within 5 mV of each other.

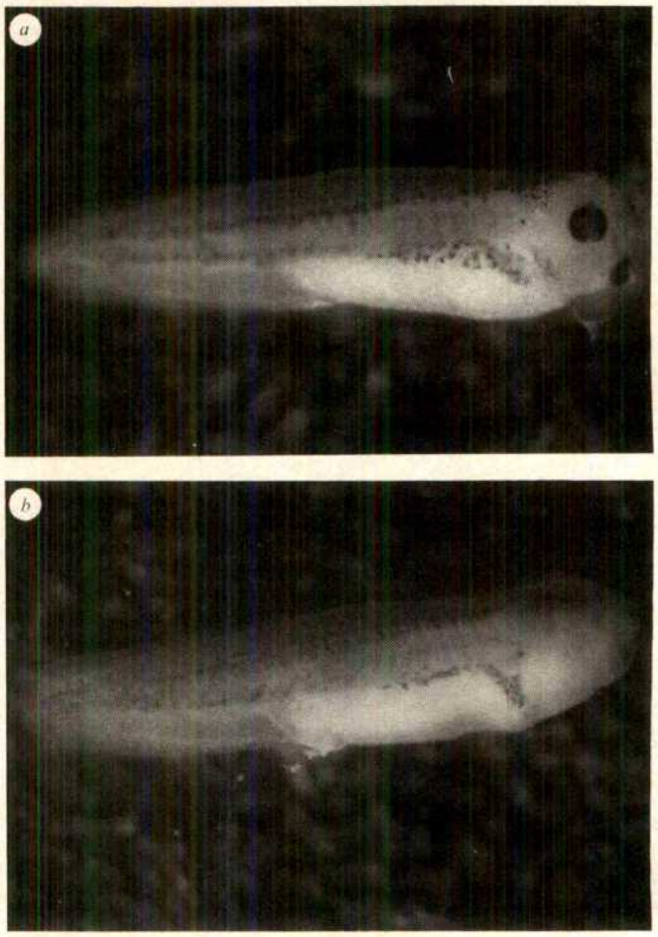

Fig. 5 A control embryo (*a*) and an embryo injected with antibody A at the 8-cell stage (*b*) photographed by S. E. Fraser prior to fixation, when the control had reached stage 36. The embryos are viewed from the right hand side. Note absence of the eye and deformed shape of the head in the antibody injected embryo. Note that the tail of the injected embryo is fairly normal. Sections through these two embryos to show the internal head structures are shown in Fig. 6.

transfer was accompanied by a reduction in electrical coupling, embryos which had been injected with Lucifer yellow and scored for failure to transfer dye were tested for the presence or absence of electrical coupling. In the whole embryo current can flow from one cell to the next through the restricted extracellular space because of the presence of tight junctions joining the outer edges of the cells. To avoid this complication, the embryos were released from their vitelline membranes and the seal into the blastocoel was broken mechanically before testing for electrical coupling. In each embryo, coupling was tested between cells lying in the uninjected animal pole region of the embryo for comparison with coupling between cells containing either antibody A or B. Figure 4 shows the results for two embryos. Injection with either antibody A (Fig. 4*a*) or antibody B (Fig. 4*b*) reduced electrical coupling to below the limits of detection. Similar measurements on 10 other embryos revealed either complete abolition of electrical coupling (8 cases), or a reduction to just above the detectable level (2 cases), between cells containing either gap-junction antibody.

The occasional failure of the antibodies to cause complete block of both dye transfer and electrical coupling is almost certainly the consequence of a large, potentially variable, amount of unassembled junction protein available in the egg. Undoubtedly, variability in the amount of antibody injected also contributes. Presumably all of the protein available to form junctional channels must combine with the antibody in order for the block to be completely effective.

These results show that two antibodies raised against a protein extracted from rat liver gap junctions are capable of blocking functional transfer of both a low molecular weight dye and small ions in the early *Xenopus* embryo. Since preliminary experiments to test the efficacy of such antibodies in a cultured rat liver cell line showed that antibody A prevented cell to cell transfer of 6-carboxyfluorescein, the results suggest that gap junctions in both *Xenopus* and rats share a determinant which is closely involved in controlling the transfer of molecules from cell to cell. This is consistent with the observed immunochemical homology (Fig. 1) and a previous report on the lack of specificity for generating cell to cell channels between heterologous vertebrate cells[18].

Developmental consequences

Cells injected with all the reagents tested, maintained normal resting potentials through many rounds of cell division and continued to divide at the same rate as other cells in the embryo. The injected embryos were examined for signs of cell death and extrusion throughout their development but no signs of death were observed. Embryos in which the injected cell was killed or injured (by deliberate over-irradiation after injection of Lucifer yellow) showed gradual failure of cleavage and cytolysis of the progeny of the injured cell. Such effects were never seen in embryos injected with gap junction antibody. Furthermore, the progeny of the cell which had been injected with Lucifer yellow at the 32-cell stage to test for dye transfer after antibody injection, were clearly visible in the living tadpole for at least 3 days. The progeny of the cell injected at the 8-cell stage contribute to both ectodermal and mesodermal derivatives on the right hand side of the embryo. Injection of either antibody A or B generated a high proportion of tadpoles with a characteristic set of abnormalities which were related to the developmental fate of the injected cell. The most frequently occurring defects were varying degrees of right/left asymmetry (63%), although some embryos (19%) failed to form brains and eyes on both sides. In asymmetric embryos the right eye frequently failed to form altogether; this was accompanied by gross underdevelopment of the brain on the right hand side. An example

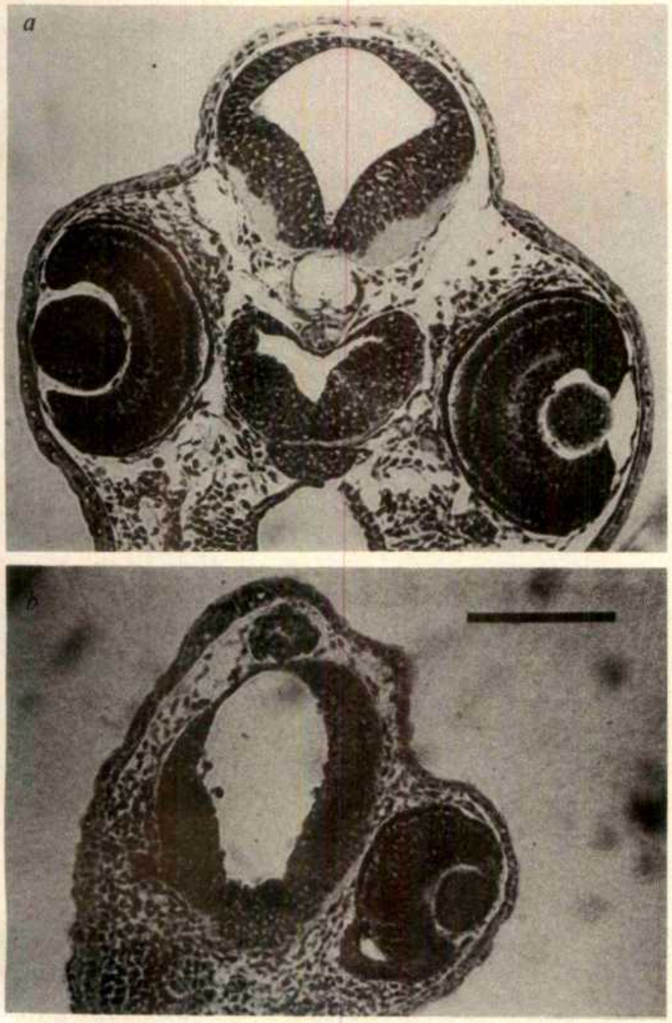

Fig. 6 Transverse section at the level of the developing eyes in a control embryo at Nieuwkoop and Faber stage 36 (ref. 24) (*a*) and an embryo of the same age which had been injected with antibody A at the 8-cell stage (*b*). Scale bar, 500 μm. The plane of section through the two eyes of the control embryo is not exactly the same because of a slight tilt in orientation. The experimental embryo shows three features of note: (1) the eye is missing on the side previously injected with gap-junction antibody; (2) the brain is the shape normally found anterior to the eyes and (3) the brain is particularly underveloped on the injected side. Embryos fixed in 2.5% glutaraldehyde in Ringer's solution overnight, washed in buffer, dehydrated in alcohols and embedded in methacrylate resin. 7 μm serial sections were cut on a Sorvall JB4 microtome and stained with haematoxylin and eosin.

of this defect in the intact embryo, produced by injection of antibody A, is shown in Fig. 5, along with a photograph of its sibling control (Fig. 5*a*). Figure 6 shows sections taken at the level of the eyes through these two embryos. In milder cases of impaired development, the notochord was shifted from its central position to the uninjected side and the brain and eyes on the right hand side were then much smaller than those on the left. Attempts to produce completely communication-incompetent embryos, by injecting antibody just before the first cleavage, or into both cells at the two cell stage, were unsuccessful; all such embryos died before gastrulation. None of the control reagents induced abnormalities above the spontaneous, low level. The abnormalities observed in control embryos were highly variable and rarely asymmetric.

Until we know how long the injected gap-junction antibody remains effective in blocking cell to cell communication and how the embryo responds to the presence of a group of non-communicating cells, it is difficult to relate the observed developmental defects directly to a role for gap-junctional communication. Nevertheless, the developmental defects induced by injection of antibodies to gap-junctional protein clearly warrant careful and detailed analysis.

Our studies show that two antibodies raised against the 27K gap-junction protein extracted from rat liver, are able to inhibit functional cell to cell communication in the early *Xenopus* embryo, assessed either as transfer of the dye Lucifer yellow or by electrical coupling. These observations provide direct evidence that the 27K protein in gap junctions is an integral component of the functional channel for cell–cell communication. Several studies have suggested that the channel is formed by the oligomeric arrangement of proteins[19,20]; this suggestion is clearly consistent with our findings. Furthermore, the disruption of intercellular communication caused by injection of antibodies to the 27K protein produces characteristic developmental defects. It should therefore now be possible: (1) to identify a molecular determinant(s) which controls the functional properties of gap junctions; (2) to further analyse the developmental consequences of blocking cell to cell transfer, in order to determine the developmental role of intercellular communication.

A.E.W. thanks the Wellcome Trust for a travel grant to enable preliminary experiments to be carried out, Scott Fraser for the hospitality and facilities of his laboratory and the MRC for support. S.G. is in receipt of an MRC Studentship. N.B.G. has received support from the NIH (grants GM 32230 and HL 28446). We thank Rosa Earls, Nigel Messenger, Lisa Satterwhite and Danna Zimmer for assistance, W. W. Stewart for a gift of Lucifer yellow and J. Hollyfield and L. Etkin for access to *Xenopus* materials in Houston.

Detection of molecular hydrogen in two merging galaxies

R. D. Joseph & G. S. Wright
Blackett Laboratory, Imperial College, London SW7 2BZ, UK

Richard Wade
Royal Observatory, Blackford Hill, Edinburgh EH9 3HJ, UK

NGC6240 and Arp 220 (IC4553) are two of the most luminous IR galaxies known[1,2]. They are also both thought to be examples of galaxy–galaxy mergers. As part of our study of interacting and merging galaxies[1,3,4] we have obtained IR spectra in the 2-μm region of NGC6240 and Arp 220 and detected the $v = 1\text{–}0$ S(1) quadrupole rotation–vibration emission line of H_2 (rest wavelength 2.122 μm) in both galaxies. (This line in NGC6240 has also recently been detected by E. E. Becklin *et al.*, personal communication.) These detections, which double the number of previously published measurements of extragalactic H_2 (refs 5, 6) suggest that the merger of two galaxies results in the production of massive quantities of shocked molecular gas. This shocked gas must cool and collapse, leading to an enormous burst of star formation. These measurements of shocked H_2 thus strengthen our earlier interpretation[1] of the extremely large IR luminosity of NGC6240 in terms of a 'super-starburst'. Arp 220 may be undergoing similar activity. We suggest that merging galaxies are a unique new class of ultra-luminous IR galaxies.

The spectra were measured on the UK Infrared Telescope (UKIRT) on the nights of 10 and 11 April 1984 using a seven-channel cooled grating spectrometer (CGS-2) with a 5 arc s aperture[7]. Wavelength calibration and the instrumental resolution of 550 km s^{-1} were derived from observations of Brackett γ (λ 2.166 μm) in the planetary nebula NGC7027. Spectra of the star BS5447 provided flux calibration. The spectra were measured at positions defined by the peak of the IR emission for NGC6240, and by the peak of the optical emission for Arp 220. The spectral coverage of the seven-channel spectrometer, ~0.023 μm, was centred on the $v = 1\text{–}0$ S(1) line of H_2 (hereafter, the S(1) line) redshifted to the recessional velocities of the galaxies. The full spectra obtained are shown in Fig. 1. The S(1) line is clearly detected in both galaxies and probably also resolved in both. The corresponding fluxes and luminosities, for $H_0 = 50$ km s^{-1} Mpc^{-1}, are given in Table 1. The luminosity in the S(1) line for NGC6240 of 10^8 $L_{\odot}$ may be compared with luminosities of 3×10^6 $L_{\odot}$ and 3×10^7 $L_{\odot}$ in this line for NGC1068 (ref. 5) and NGC3690 (ref. 6) respectively.

Using the data in Table 1 we can develop the following physical picture of the H_2 excitation in these two merging galaxies. First, this gas is almost certainly excited by shock-heating, as is the case for virtually all known examples of H_2 quadrupole emission[8]. In NGC6240, the width of the S(1) line, ~800 km s^{-1}, is identical to the widths of optical emission lines seen in a similar aperture on the nucleus, and which are thought to be shock-excited[9]. Fluorescence following absorption of UV photons is considered to be the most plausible alternative mechanism for excitation of these rotation–vibration levels. In this case, the $v = 2\text{–}1$ S(1) line should have about half the intensity of the $v = 1\text{–}0$ S(1) line[10]. Our failure to detect the $v = 2\text{–}1$ S(1) line in NGC6240 at a sensitivity similar to that reached for the $v = 1\text{–}0$ S(1) line detection, suggests that UV pumping does not contribute significantly to the excitation, and shocks remain as the most likely excitation mechanism.

Second, the mass of hot gas may be estimated by assuming local thermodynamic equilibrium at a temperature of 2,000 K (ref. 8). The luminosities in Table 1 then imply masses of excited molecular gas of ~10^5 $M_{\odot}$ and ~10^4 $M_{\odot}$ for NGC6240 and Arp 220 respectively.

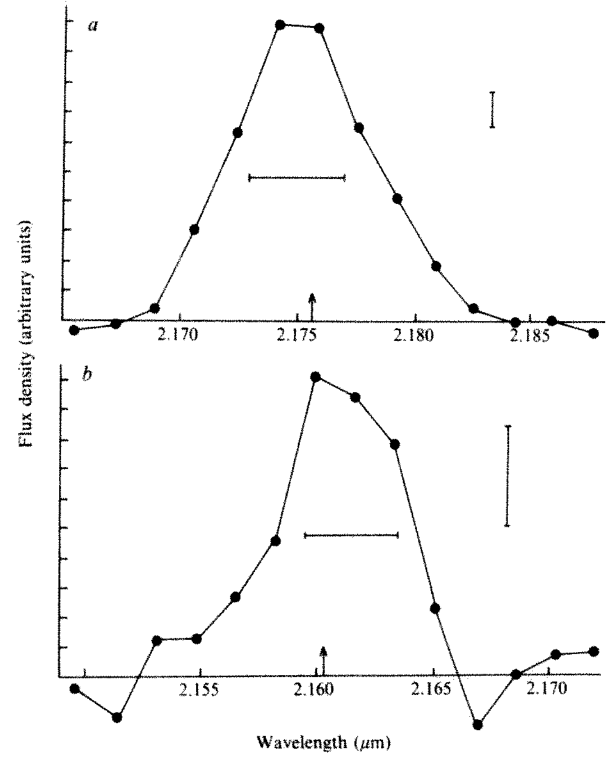

Fig. 1 Near IR spectrum of the nucleus of *a*, NGC6240; *b*, Arp 220 in a 5 arc s aperture. The arrow shows the wavelength of the 2.122 μm S(1) line redshifted to the radial velocity of the respective galaxies. The spectrum has been ratioed with the standard, smoothed using a triangular function, and the baseline has been subtracted off. The vertical bar represents the 1σ error per point, and the horizontal bar represents the instrumental resolution.

Third, we can use simple energetic arguments to investigate the underlying source driving the shocks. The gas cools to a temperature <1,000 K in about 3 yr (ref. 11), so in NGC6240 the shock excites about 3×10^4 $M_{\odot}$ of gas per year. The force, $\dot{m}v$, required to drive such a shock at a speed of ~20 km s^{-1} is ~5×10^{36} dynes. By comparison, the radiation pressure, L/c, of these ultra-luminous galaxies, with L_{IR} ~10^{12} $L_{\odot}$, is ~10^{35} dynes. Despite the high luminosities, radiation pressure is clearly insufficient to drive the shocks which we infer are present in these galaxies.

These objects are the results of galaxy–galaxy mergers, and are both likely to be examples of 'super-starbursts'[1,2]. Two obvious mechanisms for driving the shocks are either the relative kinetic energy of the collision, or mass outflow from the early-type stars in the starbursts. To investigate the relative contributions of these two processes we can use the ratios of the luminosities in the S(1) lines to the total IR luminosities. This ratio should have a characteristic value if the H_2 is excited by mass outflow from young stars, and the IR luminosity is provided by the luminosity of the early-type stars which is thermalized by dust and re-radiated in the IR. These ratios are presented in Table 2, along with that for Orion, a 'typical' star formation

Table 1 Fluxes and luminosities in the S(1) line

Galaxy	Flux (W m^{-2})	$L(L_{\odot})$
NGC6240	$(15\pm1)\times10^{-17}$	1×10^8
Arp 220	$(2.5\pm0.5)\times10^{-17}$	9×10^6

Table 2 The ratio of luminosity in the S(1) line to total, IR luminosity

Object	Ratio $(L(\mathrm{S}(1))/L_{\mathrm{IR}})$
NGC6240	20×10^{-5}
Arp 220*	1.2×10^{-5}
Orion	1.2×10^{-5}
NGC3690	3×10^{-5}
NGC1068	0.9×10^{-5}

* See comments in text.

region in the Galaxy[12]. For comparison, we have also included these ratios for the other two galaxies in which H_2 has been detected, NGC1068 and NGC3690 (refs 6 and 12). We have used our 10–20 μm UKIRT photometry[1] to obtain the appropriate IR luminosity for the nucleus of NGC6240 in a 5 arc s aperture, similar to that used for the S(1) observations. These measurements give an IR continuum spectrum of similar shape to the large aperture IRAS photometry[1] and imply a luminosity $L_{\mathrm{IR}} \sim 5\times10^{11}\ L_{\odot}$, a factor of 4 less than that inferred from the IRAS results. We have, therefore, used a similar factor to scale the IRAS luminosity for Arp 220 (ref. 2) to that expected in a 5 arc s aperture.

Table 2 shows that all the galaxies, with the exception of NGC6240, could be excited by mass outflow from star formation regions similar to Orion. NGC6240 is clearly the exception, by a factor of more than 10, and it is likely that mechanical energy in the galaxy–galaxy collision has provided most of the energy required to heat the H_2 gas. If we assume a galaxy mass of $\sim10^{12}\ M_{\odot}$, 10% of which is gas, and a relative velocity between the colliding galaxies of ~300 km s^{-1}, then this process supplies an energy of $\sim10^{59}$ ergs. For an efficiency of 0.002 in coupling shock energy into the S(1) line[13], the mechanical energy in the collision can excite the gas at the observed rate for a time $\sim2\times10^{7}$ yr. For Arp 220 the luminosity ratio in Table 2 is entirely consistent with excitation by mass outflow from star formation regions. However, it is very likely that we have not measured the maximum S(1) line intensity in Arp 220, since we observed only the optical nucleus. Given the physical similarity between NGC6240 and Arp 220, it would be surprising if a better measurement of the S(1) line flux did not result in a luminosity ratio closer to that for NGC6240.

There are several important conclusions to be drawn from these measurements. First, the existence of massive quantities of shocked molecular gas, in excess of that expected for star formation regions alone, is consistent with what might be expected when galaxies merge, and tends further to confirm other indications that NGC6240 is indeed the merger of two gas-rich galaxies. Second, both these galaxies are probably undergoing an episode of star formation of exceptional intensity, with shocked, and, therefore, dense H_2 produced at the rate of 3×10^{3} to $3\times10^{4}\ M_{\odot}\ \mathrm{yr}^{-1}$. This gas will cool rapidly, collapse and fragment, and result in a burst of star formation. The enormous mass of molecular gas that is shocked over any reasonable lifetime for this process, and its expected spatial extent on a scale of kpc if the shocks are merger-driven, as seems to be the case for NGC6240 at least, will produce an episode of rapid star formation of unusual spatial extent and intensity, that is, a 'super-starburst'. Finally, because dust is required to form the H_2 molecules[14], there must be dust present. It will thermalize the radiation from the newly-formed stars and re-radiate it in the IR. Thus these super-starbursts are likely to produce ultra-luminous IR galaxies. We have suggested previously[1] that NGC6240 is a paradigmatic example of such a process, and the detection of shocked H_2 strongly supports this interpretation. As a consequence, merging galaxies may be a unique new class of galaxies exhibiting super-starbursts and ultra-large IR luminosities.

This picture of interaction-induced shocks, which then trigger a super-starburst in merging galaxies, is physically coherent and plausible. However, there remain some fundamental unanswered questions concerning the details of these processes. First, how common might such a phase of vigorous H_2 excitation be among merging galaxies generally? As these two galaxies were selected for study on the basis of their large IR luminosities, it is difficult to attempt generalizations about the time scale of the phase of luminous H_2 emission on the basis of these measurements alone. However, the fact that the S(1) line is so luminous in two merging galaxies suggests that the episode of this activity may be a significantly large fraction of the time over which the morphological disturbance would be recognized as a merger. The dynamical simulations of Toomre and Toomre[15] and Wright[16] suggest that the tidal 'tails' resulting from an interaction persist for periods of the order of 10^{9} yr. This is longer than the 2×10^{7} yr estimated above for the time merger-driven shocks can excite the gas in NGC6240 at the observed rate. Despite the rather large uncertainties in this estimate, the duration of luminous H_2 emission powered by the merger is unlikely to be more than 10^{8} yr. Even if the H_2 were mostly excited by mass outflows from star formation regions, the time scale for such starbursts is probably $\lesssim10^{8}$ yr (ref. 17). This is also rather short compared with the merger lifetime. So, if these time scales are approximately correct, we would expect that only ~10% of the galaxies recognizable as mergers from their morphologies are currently undergoing a phase of activity similar to that in NGC6240.

Perhaps even more intriguing is the fact that we failed to detect the Paschen α hydrogen recombination line in NGC6240 at a comparable sensitivity to that reached in the S(1) line measurements. (We measured Paschen α because Brackett α, at a rest wavelength of 4.051 μm, is at the edge of the atmospheric transmission window at the redshift of NGC6240.) For those objects in which the H_2 excitation is thought to be due to mass outflows in star formation regions—NGC1068, NGC3690, and Orion—the Brackett γ line flux is within a factor of 2 of the S(1) line flux. Although we have shown that in NGC6240 the S(1) line is ~20 times stronger than expected for excitation from star formation regions, the Paschen α line is also expected to be about 12 times stronger than Brackett γ from recombination theory[18,19]. Because it is difficult to avoid the conclusion that the high IR luminosity of NGC6240 is due to a massive burst of star formation[1], our failure to detect the Paschen α recombination line is indeed surprising. Whether this can be understood in terms of a complex geometry for dust extinction, self-shielding by the H_2, or perhaps a starburst initial mass function with fewer high mass stars, requires further detailed analysis. Such an analysis, supplemented by additional spectroscopic results for these and other interacting galaxies, is in preparation.

We thank Charles Telesco, James Graham and especially Ian Gatley for stimulating and informative discussions. G.S.W. is a research student supported by the UK SERC.

Note added in proof: Molecular hydrogen emission has been discovered in these two galaxies by several independent observers as listed in IAU Circ. No. 3968.

Detection of radiation from a heated and modulated equatorial electrojet current system

R. J. Lunnen*, H. S. Lee*, A. J. Ferraro*, T. W. Collins† & R. F. Woodman‡

* The Communications and Space Sciences Laboratory and
† Electronic Design Services, Department of Electrical Engineering, Pennsylvania State University, University Park, Pennsylvania, USA
‡ Geophysical Institute of Peru, Apartado 3747, Lima, Peru

In May 1983, ionospheric heating experiments were conducted using the Jicamarca very high frequency (VHF) radar facility located ~11 km east of Lima, Peru. Experiments involving high frequency (HF) heating of the lower *D*-region of the ionosphere were successfully conducted during 1982 using the Arecibo, Puerto Rico HF transmitter located 5 km east at Islote, Puerto Rico. These local experiments had characterized the signal radiated from a heated and modulated ionospheric current system near the mid-latitudes. A long-path signal had also been received in September 1982 at Salinas, Puerto Rico from a mid-day equatorial electrojet, heated and modulated by the Jicamarca facility. We have investigated the characteristics of the local signal that would be radiated from a strong equatorial electrojet when heated and modulated, and report here that at the geomagnetic equator they were similar to, but less intense than, those observed at Arecibo, Puerto Rico due to parameter differences. This radiation is believed to be the first detected from a heated and modulated equatorial electrojet current system in the Western Hemisphere.

The VHF heating experiments involved a research team from The Pennsylvania State University working in close cooperation with the Jicamarca Radar Observatory of the Geophysical Institute of Peru. Stubbe *et al.*[1] successfully detected radiation from the polar electrojet above Tromso, Norway and Ferraro *et al.*[2] have detected radiation from the dynamo current system above Arecibo, Puerto Rico. The Peruvian experiment involved heating the equatorial electrojet current system with the Jicamarca radar (76°52′ W, 11°57′ S, dip 2° N). ~5,547 MW of effective radiated power (with linear polarization at 49.920 MHz and a 2° beamwidth, modulated at a 5% duty cycle with a square wave at a frequency of 2.5 KHz) was radiated vertically into the atmosphere. The radar was then operated on a heating and cooling cycle of 2 min on and 2 min off. This type of experiment has been repeated many times using the Islote, Puerto Rico heating transmitter of the Arecibo Observatory; however, the parameters of the Islote transmitter differ from those of Jicamarca. Specifically, the usual Isolote heating frequency is 3.170 MHz and the duty cycle of the modulating signal is 50%. The two transmitting facilities are compared in Table 1.

The basic physics of electromagnetic radiation from a heated, modulated ionosphere at frequencies <30 KHz is influenced by the fact that ionospheric conductivity depends on the temperature of the electrons. The conductivity of the heated ionosphere varies periodically with the frequency of the heating radiation. The natural currents (such as, dynamo, polar electrojet, and equatorial electrojet) which pass through the heated region are modulated by conductivity changes, with radiation of energy at the modulating frequency having been detected.

The receiving system used a synchronous detector to measure the in-phase and quadrature components of the signal. A balanced loop 1 m in diameter consisting of 200 turns of number 14 wire with a tuned Q of ~55 at 2.5 KHz was used. A 0.5-m one-turn coaxially mounted loop was used for calibration using the procedure outlined in ref. 3. The signal was amplified, filtered, sampled and stored using a microcomputer with floppy diskette storage. Subsequent signal processing on the VAX 11/780 revealed the signal amplitude and phase as well as the Fast Fourier Transform (FFT) of the 2 min on–2 min off signal envelope.

Table 1 Comparison of transmitting facilities

Effective radiated power (MW)	160–320	5,547

* Values present during experiment.

The long-path experiment was conducted on 17 September, 1982 with the Jicamarca radar operating as previously described. The receiving equipment was located at Salinas, Puerto Rico (17°59′ N, 66°16′45″ W). Salinas is located ~67 km south east of the Isolate transmitter and ~3,532 km from the Jicamarca Peru facility.

Figure 1 shows the 2.5 KHz FFT received on 17 September 1982 at Salinas, Puerto Rico. The dominant amplitude of 4.17 mHz corresponds to the on/off period of 240 s. The conversion of the amplitude to magnetic field strength at the loop was not accomplished for these data; however, when compared with the local primary component of 4.17 mHz, in volts, the local signal is stronger.

In May 1983 the receiving equipment was installed ~9 km south of the Jicamarca Observatory as shown in Fig. 2. A mountain range of several thousand feet separated the transmitter and the receiver. The transmitter was operated as previously described with two of four transmitters feeding the entire array. This limited the effective radiated power to 5,547 MW throughout the experiment. The high-power radiation capabilities were not utilized as the transmitter was undergoing modification at the time of the experiment. The radiation was linearly polarized with the electrical field in the north–south direction. The electrojet echo strength was monitored during the experiment with maximum returns near local noon. An antenna trap at 49.920 MHz was used to ensure that direct ground radiation would not affect the data. A VHF receiver was used to check the tone of the received signal from the transmitter. The tone scintillation on the 50 MHz receiver verified that there was a strong electrojet current during the received signal period.

The VHF heating test was conducted on 4, 5 and 9 May 1983.The dominant modulating frequency used was 2.5 KHz. Four hours of testing at 2.5 KHz during the first day were consumed in technical considerations of tuning receiving system calibration and general coordination to ensure valid test results. The receiving loop has its strongest quality factor at 2.5 KHz and a solid data base at this frequency from Arecibo testing was available for comparison. Only 1 h of testing was devoted to 5.0 KHz, 1.0 KHz and 0.08 KHz to complete a limited overall test schedule. No signals were found at these three frequencies; however, limited testing coupled with system parameters, past experience, and the need for tuning and calibration makes premature conclusions unwise.

The results at 2.5 KHz on 5 and 9 May 1983 were similar so only the latter are shown in Fig. 3. The signal radiated from the heated and modulated electrojet was observed within a few-hours window at local noon, chosen to coincide with a strong electrojet current. The received signal exhibited a cyclic character where it was visible in some portions of data and submerged in noise during others.

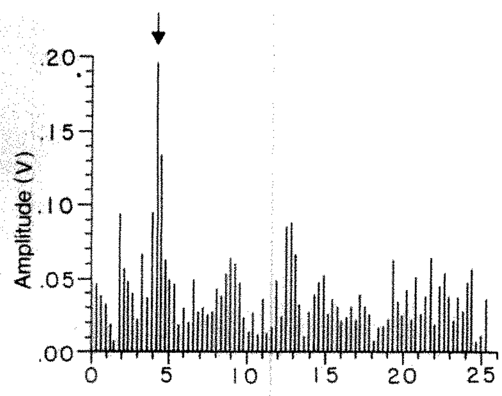

Fig. 1 Long-path amplitude spectrum, 2,500 Hz, Jicamarca, Peru to Salinas, Puerto Rico, 1600–1700 UT, September 1982.

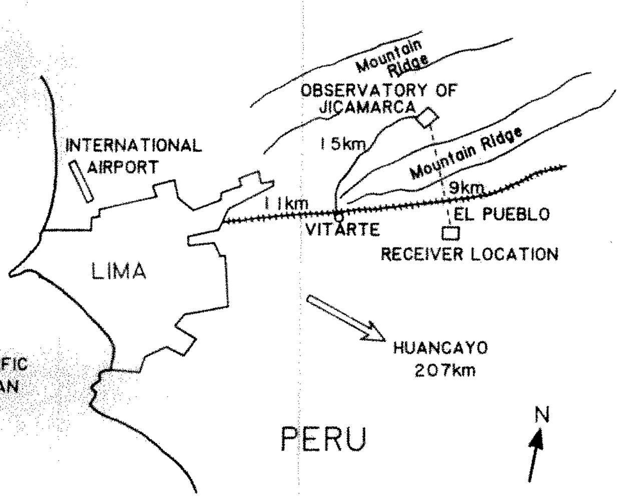

Fig. 2 Relative locations of the Radar Observatory of Jicamarca, Peru and the VLF/ELF receiver location.

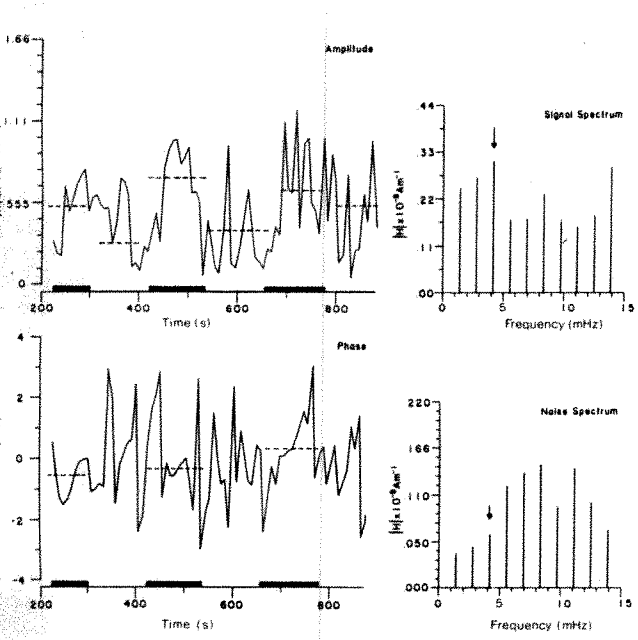

Fig. 3 Amplitude, phase and spectrum of a local Jicamarca, Peru signal at 2,500 Hz, 1345–1400 UT, 9 May 1983, compared with noise spectrum.

In Fig. 3, the amplitude and phase of the 2.5 KHz on 9 May are augmented with dashed lines to show average values. The intensity of the amplitude during the 2-min heating cycle, indicated by the dark portion of the time axis, was an order of magnitude less than a typical signal recorded at Arecibo. This is primarily attributed to the narrow beamwidth, higher heating frequency, and lower duty cycle of the Jicamarca radar compared with the Islote facility where parameters are closer to ideal. The phase tracking while the signal was being received is also characteristic of the Arecibo signal received. The amplitude spectrum shows the predominance of the 4.17-mHz spectral line. A pure noise spectrum is shown for comparison. The noise sample was recorded the day before testing because it could not be done while the experiment was in progress. This explains the apparent difference in amplitude of anything other than the primary frequency component. In this case, the calibration procedure was used to calculate the magnetic field strength at the loop, for comparison with Arecibo data recorded in 1983 and 1984.

Bismuth in interplanetary dust

Ian D. R. Mackinnon & Frans J. M. Rietmeijer

Microbeam Inc., Mail Code SN4, NASA Johnson Space Center, Houston, Texas 77058, USA

Samples of a large (~60 μm) chondritic porous (CP) aggregate collected from the stratosphere have been analysed in detail by analytical electron microscopy (AEM). Previous studies of CP aggregates have shown that they are extraterrestrial in origin[1–3] and may be related to cometary debris[4]. CP aggregates are dissimilar to C1 and C2 carbonaceous chondrite matrices and many have not been significantly altered by thermal or radiation processes since their assembly[5]. We report here a high concentration of Bi_2O_3 grains within the large CP aggregate designated W7029*A (~60 μm) and suggest they formed by rapid heating (~300 °C) of elemental Bi grains within the aggregate during atmospheric entry. We examine the possibilities for terrestrial Bi contamination of CP aggregate W7029*A but judge them unlikely. Enrichment of elemental Bi within components of extraterrestrial materials is consistent with a nebula condensation model[6] and implies that Bi within CP aggregate W7029*A may have formed at a late stage of the condensation process.

W7029*A was collected from the stratosphere as part of the Cosmic Dust Program at Johnson Space Center[7]. Before allocation, a small (<10 μm) fragment of W7029*A was removed from the collection surface for preliminary examination. Scanning electron microscopy (SEM) and bulk chemical analysis by the Cosmic Dust Preliminary Examination Team[7] indicate that aggregate properties follow the criteria for a typical CP aggregate[4]. Portions of the aggregate were transferred from the collection surface to holey carbon films mounted on Be grids and gently washed with hexane in order to minimize contamination by the silicone oil used in the collection process. CP aggregate W7029*A is fragile and readily disaggregated on removal from the collection surface. Thus, individual fragments of the aggregate were suitably dispersed on carbon films for detailed AEM investigations. Electron microscopy on the allocated sample was performed with a modified JEOL 100CX AEM and with a Phillips EM420 AEM. Accelerating voltages of 100 and 120 kV, respectively, were used for all samples analysed. Each individual fragment or grain from this portion of the aggregate was then identified by a combination of high-resolution imaging, electron diffraction, electron energy-loss spectroscopy or energy dispersive spectroscopy (EDS). Modal analysis of CP aggregate W7029*A indicates that the following phases are predominant: carbon-rich phases (~47%), layer silicates (~11%), other silicates (~12%) and metals and/or oxides (~8%). Nine Bi grains (comprising ~50% of the metals or oxides) have been identified.

A typical example of a Bi grain from CP aggregate W7029*A is shown in Fig. 1. This conventional transmission electron microscopy (TEM) image shows an angular grain, ~350 × 400 nm in size, with a small (<2 nm) rim of less electron-dense material. The nature of the rim is unknown, but thin rims of a similar nature have been observed on individual crystals of cohenite[5] and (Fe, Ni) carbides[8] in other CP aggregates collected from the stratosphere. All Bi grains show a narrow size range between 0.5 and 0.25 μm. EDS analyses of all grains show the characteristic M and L lines for secondary X-ray fluorescence of Bi (Fig. 2). Determination of Bi from EDS spectra within the 0–10 kV range is difficult due to overlap of the Bi M line with the K line for sulphur (ref. 9). However, the higher energy-line positions (between 10 and 20 kV) and intensities ($L\alpha > L\beta > L\gamma$) provide an unambiguous identification of Bi. The inset in Fig. 2 shows the lower energy end of an EDS spectrum taken with a windowless energy dispersive spectrometer. A small peak for the oxygen K line is evident. The intensity of the O peak is significantly higher than that observed in spectra from carbon substrates containing residual silicone oil. The lower intensity of the O peak relative to the Bi M line is probably due to self absorption of the soft oxygen X rays.

Electron diffraction (inset, Fig. 1) from all Bi grains indicates that they are single crystals and confirm the oxide composition from EDS data[10]. Bi metal forms in space group R$\bar{3}$m with cell dimensions $a = 4.537$, $c = 11.838$ Å. Bi forms two oxides, Bi_2O_3 and Bi_2O_5, the former occurring as three well defined polymorphs[11]: monoclinic, tetragonal and body centred cubic. Two other polymorphic forms of Bi_2O_3 have also been described: oxide (I) and oxide (II)[12]. The structures of these latter forms are not well determined, but oxide (I) has a simple cubic structure with $a = 5.65$ Å (refs 12, 13). All grains observed in CP aggregate W7029*A index according to this simple cubic cell for Bi_2O_3 (ref. 12).

The geochemical properties of elemental Bi are unique and provide a convenient set of independent criteria to argue against terrestrial contamination of CP aggregate W7029*A during its entry into the stratosphere or after collection. Terrestrial Bi may enter the stratosphere by natural or anthroprogenic processes. However, we shall present arguments which show that, at the time, neither of these processes was significant for the collection of CP aggregate W7029*A.

Bi is not abundant in the terrestrial crust (ranges between 0.1 and 0.2 p.p.m.)[14] and is commonly found in the native state with traces of As, S and Te (ref. 15). Bi can also be found in sulphide minerals in veins associated with Ag–Pb ore deposits or in replacement deposits formed by hydrothermal solutions[15]. Although Bi minerals occur in pneumatolytic deposits associated with volcanic action, the Bi content of volcanic plumes is not known with any degree of certainty. Nevertheless, the collection period for flights which sampled W7029*A does not correlate with any reported volcanic eruption, still less a volcanic plume which penetrated the Northern Hemisphere tropospheric–stratospheric boundary. Thus, the lack of sulphur or other commonly associated elements within these Bi grains and the low concentrations of Bi minerals in the Earth's crust argue against a natural terrestrial origin for Bi in W7029*A.

Anthropogenic Bi contamination may occur through infall of debris from higher altitudes[16], atmospheric nuclear explosion plumes, or at a later stage of the collection and curation process. Alloys and oxides of Bi are used in the space and materials science industries[17]. However, in the most common applications (cosmetic and medicinal preparations) Bi is not used in great volumes, and even in low melting temperature alloys the metal is consumed in small quantities[15]. Bi within W7029*A derived from either of these sources should show trace or remnant compositions characteristic of the relevant alloy or oxide used in space or on Earth. Such compositional variety is not observed for any Bi particle in CP aggregate W7029*A. Furthermore, a survey of the collection and curation procedures at Johnson Space Center indicates that Bi metals, oxides or alloys are not contaminants at any stage of the process. An extensive survey of all possible forms of contamination within our sample preparation and analysis procedures has been undertaken during the past 2 yr. This survey has included detailed mapping of TEM grids before and after supply to the Curatorial Facility, SEM and AEM analysis of all forms of plastic, epoxy and mounting materials. Grains containing Bi have not been observed within these potential laboratory contaminants or unusual non-chondritic stratospheric particles.

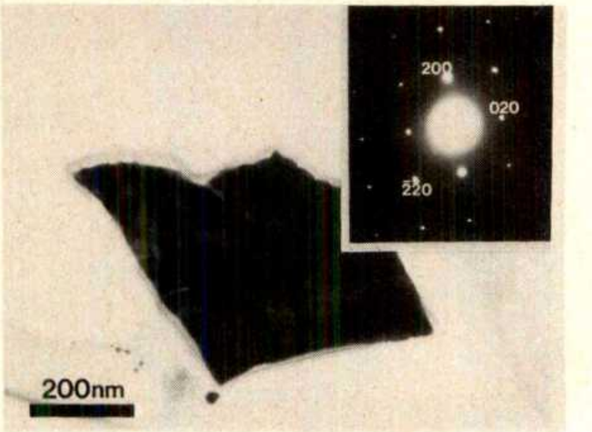

Fig. 1 TEM image of a typical Bi grain (mounted on holey carbon film) from CP aggregate W7029*A. The electron diffraction pattern (inset) is indexed according to a simple cubic form of Bi_2O_3.

Bi has one naturally occurring isotope (^{209}Bi) with a half life of 2×10^{18} yr (ref. 15). Five other isotopes of Bi occur as the daughter products of uranium or thorium decay. However, the longest half-life for any daughter product from these decay chains is ~5 days (ref. 15). The most recent recorded atmospheric nuclear test in the Northern Hemisphere occurred in late 1974[18,19]. Artificial tritium fallout studies at the South Pole indicate that stratospheric half residence times for gaseous species (for transport from the Northern Hemisphere to the South Pole) is ~20 months. Therefore, we infer that particulates will remain in the Northern Hemisphere stratosphere in normal conditions for less than 20 months. Any daughter Bi from a nuclear explosion plume in the Northern Hemisphere would have decayed and been transported from the stratosphere by the time CP aggregate W7029*A entered the stratosphere. If the aggregate itself was a product of an atmospheric nuclear explosion, this set of observations would be inconsistent with the present consensus of opinion in the field of interplanetary dust[1–5]. In addition, transport times[19] and settling rates for stratospheric particles of irregular shape[20] do not support a nuclear blast origin for CP aggregate W7029*A.

Terrestrial Bi from natural or anthropogenic sources may contaminate CP aggregates within the stratosphere during the limited time they settle from rest velocity height to the collecting altitude. (This time period is calculated[20] to be <150 days.) In addition, for a terrestrial origin of Bi, particle clustering must be shown to be significant during the period of collection of CP aggregate W7029*A. Clustering of particles is primarily dependent on the relative concentration of particles within the stratosphere and is significant for anomalous conditions such as the El Chichón stratospheric cloud[20]. However, during normal collection periods, particle concentrations within the stratosphere are significantly lower than during the collection period through the El Chichón cloud[20,21]. Evidence for particle clustering during

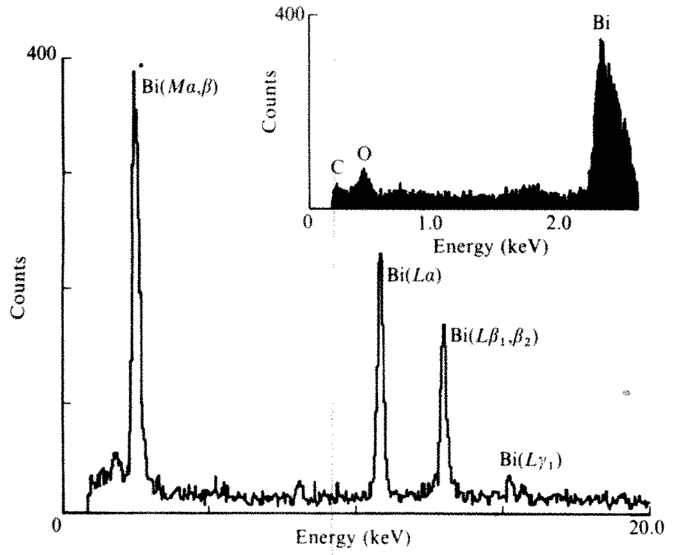

Fig. 2 Energy dispersive spectra from the grain shown in Fig. 1. Only Bi *M* and *L* lines are present with a conventional Be window detector. The windowless energy dispersive spectrum (inset) reveals a significant oxygen peak above background from the substrate. See text for details.

ambient stratospheric conditions has never been reported since the inception of the flat-plate collection process. We believe that particle clustering can occur in these conditions, but in very limited circumstances. These circumstances would primarily involve the most abundant stratospheric particles (such as Al spheres and fragments from solid rocket fuels[22,23] and would tend to include the abundant smaller size fractions[24,25]. Al-rich spheres or fragments from rocket debris have not been observed in the complete W7029*A aggregate, nor in any portion allocated for this study. Therefore, we suggest that particle clustering (and contamination by terrestrial Bi grains) is not significant for CP aggregate W7029*A.

Bismuth oxide may form from elemental Bi in a variety of conditions involving heating and oxidation. Throughout the lifetime of CP aggregate W7029*A, major periods of heating may have occurred during interplanetary passage or on entry into the Earth's atmosphere. During the latter process, oxidation may also occur. An understanding of the formation conditions for Bi_2O_3 and probable temperature profiles for micrometeors in Earth-crossing orbits may place constraints on the transformation of elemental Bi to Bi_2O_3 within CP aggregate W7029*A.

Fraundorf[26] has used typical entry parameters for micrometeors in Earth-crossing orbit to calculate temperature profiles for different size particles at different densities as they enter the stratosphere. Although the model does not strictly apply to CP aggregate particles, we use this formulation to estimate that a 60-μm size CP aggregate may have experienced maximum temperatures between 800 and 950 °C for a few seconds during atmospheric passage to 20 km altitude. Fraundorf's model[26] does not account for the complex shapes and heat capacities inherent in a typical CP aggregate. Calculations are based on an aggregate size ~60 μm and bulk densities ranging between 0.5 and $1.0\ g\ cm^{-3}$. Aggarwal and Goswami[12] have produced the simple cubic form of Bi_2O_3 by rapidly heating Bi film in air or in partial vacuum ($\sim 10^{-2}$ atm) between 250 and 300 °C. Oxides formed at higher temperatures (using a Bunsen burner flame) melted during oxidation[12]. This method for simple cubic Bi_2O_3 formation is kinetically favourable and suggests that the Bi grains in CP W7029*A were heated to ~300 °C during atmospheric entry. The apparent absence of tetragonal Bi_2O_3, which forms at higher temperatures (~900 °C; ref. 11), suggests that the range of temperatures experienced by Bi grains on entry is between 300 and 900 °C. Interpretation of data from associated minerals within this aggregate[27] indicates that many particles did not experience temperatures as high as 800 °C. We have shown that on average, temperatures on entry for CP aggregate W7029*A did not exceed 400 °C (ref. 27). These results are consistent with a known mechanism and our temperature estimate for heating Bi grains on atmospheric entry. Limited periods of pulse heating may also occur during interplanetary orbit, but with less certainty and a lower probability of oxidation. Therefore, we believe that CP aggregate W7029*A contained elemental Bi which transformed to Bi_2O_3 by pulse heating to 300–400 °C on entering the Earth's atmosphere.

In cosmochemistry, Bi is important because it is the heaviest stable element and it is highly volatile. Bi is present in variable, trace concentrations in meteorites and is most abundant in carbonaceous chondrites[28]. Individual meteorites from other groups also show high abundances of Bi (for example, the unequilibrated ordinary chondrite (UOC) Meso-Madaras[28]) though, in general, the average bulk analysis for each group is less than carbonaceous chondrites. Individual grains of Bi or Bi_2O_3 have not yet been observed in any meteorite. All previous attempts to determine the presence of Bi within meteorites have used optical microscopy, electron microprobe or bulk chemical techniques. These techniques cannot provide the same spatial resolution as AEM and therefore do not allow direct mineralogical comparisons between CP aggregate W7029*A and Bi-rich meteorites. With further AEM studies, it may be possible to identify the form and nature of Bi minerals in meteorites. Nevertheless, we use bulk meteorite data and current theories of Solar System evolution to provide some insight on the possible cosmochemical significance of Bi within CP aggregate W7029*A.

The unique properties of Bi have been used to predict its relative abundance within meteorites using a two-component model for condensation from a nebula gas[6]. The two-component model correctly predicts the mean abundances of Bi in carbonaceous chondrites (relative to Cl chondrites)[6,29,30]. This fractionation model has also been used to calculate accretion temperatures for ordinary chondrite meteorites[29–31], based on the abundances of volatile elements including Bi. In addition, the predicted siderophile nature of Bi in nebula conditions[31] has been confirmed by a study of Bi distribution in kamacites in the UOC Kohar[32]. (Note that both Meso-Madaras and Kohar are mildly metamorphosed Class II, L3 ordinary chondrites[33].) A material termed 'mysterite' has been proposed for ordinary chondrites with unusually high Bi abundances (such as Suphee) and low petrological type[34]. Mysterite is associated with dark clasts within these chondrites and occurs as a Tl-poor or a Tl-rich variety[34]. Higuchi *et al.*[34] suggest that these two components formed as late condensates from a solar nebula that collected volatiles which were left behind by earlier generations of chondrites. Independent evidence that these processes may occur in the region of the solar nebula sampled by these clasts has been provided by Davis *et al.*[35].

The agreement between theory and observations for the nebula condensation of Bi within the frame of reference provided by chondritic meteorites suggests that the implicit assumptions made by Larimer[31] for two-component model calculations may also apply to other primitive materials within our Solar System. The absolute age of CP aggregates has proved difficult to determine experimentally. CP aggregates may prove to have a cometary origin[4], and thus, some individual aggregate grains may have formed during our early Solar System evolution[36]. For the purposes of this study, we assume that CP aggregates are potentially primitive extraterrestrial materials, that Bi will occur in primitive materials as a metal and that the condensation temperature for Bi at nebula pressures between 10^{-3} and 10^{-6} atm is between 180 and 225 °C (ref. 31). To estimate the minimum abundance value for Bi within CP aggregate W7029*A, we assume the bulk density of the aggregate is $0.5\ g\ cm^{-3}$ and that its mass is 10^{-8} g. Using these values, we estimate the abundance of Bi within CP aggregate W7029*A to be at least in the p.p.m. range. This value for Bi suggests a considerable localized enrichment relative to cosmic abundance values[31]. Enrichment of Bi within components of extraterrestrial materials is consistent with a nebula condensation model[6] and implies that Bi within CP aggregate W7029*A formed at a late stage of the condensation process.

Richard McConnville and John Fahey of the Applications Laboratory, Philips Electronic Instruments Inc. are acknowledged for provision of the windowless energy dispersive spectrum shown in Fig. 2. F.J.M.R. is an NRC Research Associate at the Johnson Space Center.

Occurrence of oxidized components in Qingzhen enstatite chondrite

E. R. Rambaldi*, R. M. Housley† & R. S. Rajan*

* Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California 91109, USA
† Rockwell International Science Center, Thousand Oaks, California 91360, USA

Clues to the early history of the Solar System can be acquired by studying the properties of highly unequilibrated chondrites. These chondrites are thought to preserve an almost unaltered record of nebular processes[1–3]. Here we show that the most unequilibrated enstatite chondrite[4], Qingzhen, contains a population of enstatite grains which appear to have formed under more oxidizing nebular conditions than the bulk of the meteorite, which is highly reduced. These grains are black in transmitted light because of the presence of micrometre-sized inclusions of Ni-poor, Cr-rich metal and occur either isolated within the matrix or in chondrule interiors. Even though subsequent *in situ* reduction has led to the nucleation of metal, in most cases the FeO content of the enstatite grains still falls above the range found in the reduced portion of the meteorite. The textural occurrence of these grains argues against their having been introduced during collision of Qingzhen with an oxidized meteorite. Most likely, they originated in the same general nebular neighbourhood as the reduced bulk Qingzhen material and were subsequently transported into the reducing environment either before or during the process of chondrule formation. The discovery of this once-oxidized material in Qingzhen poses significant constraints on the existing models of formation of reduced matter in the Solar System.

The enstatite chondrites are characterized by an assemblage of highly reduced mineral phases[5–7]. Elements which are predominantly lithophile in other chondrite groups, display in enstatite chondrites, chalcophilic or siderophilic properties. Part of the Si is present in solid solution in the metal or as the Ni–Fe silicide perryite, and the bulk of the Fe occurs as the metal kamacite and the sulphide troilite. The ferromagnesian silicates (low-Ca clino- and orthopyroxene) have very low FeO contents. The FeO/(FeO+MgO) ratio in these minerals ranges from 0.0004 to 0.1, in contrast to values of 0.15 to 0.30 found in the olivine and pyroxene of ordinary chondrites[7,8].

The Qingzhen meteorite contains well defined chondrules and chondrule fragments surrounded by a population of metal, sulphide and enstatite grains. Some of the latter are black in transmitted light and have an average FeO content three to five times higher than enstatite in the chondrule interior[9], indicating formation under more oxidizing conditions than the bulk of the Qingzhen meteorite.

Sample A is an 80×120 μm black enstatite grain which contains fine-grained metallic inclusions (Fig. 1*a*) oriented subparallel to the crystallographic planes of the mineral. An enlarged portion of sample A (Fig. 1*b*) shows that the metallic inclusions tend to form small clusters or coalesce into larger grains surrounded by optically metal-free enstatite. Glass inclusions are also present. The composition of the enstatite in the metal-free areas is given in Table 1 (A1). The rather high total of this analysis (101.87) indicates an excess FeO (~2%) due to the presence of ultrafine metallic inclusions. The metal particles consist of almost pure Fe, and are Cr-rich and Ni-poor (Table 2, A4) relative to the average metal composition in the Qingzhen matrix. Nickel-poor metal can be produced during reduction of ferrosilite ($FeSiO_3$) originally present in solid solution within the pyroxene. The reduction reaction: $FeSiO_3 \rightarrow Fe^0 + SiO_2 + 1/2O_2$ produces free SiO_2. Inclusions of SiO_2-rich glass are found within the enstatite (Table 1, A3).

An approximate estimate of the FeO content of sample A before reduction was obtained by means of broad beam analyses of large areas of the grain (Table 1, A2), assuming absence of pre-existing metal and no metal loss after reduction. The analytical techniques used in this study do not allow for resolving the amount of Fe present as metal from that present as FeO within the enstatite. The bulk Fe present in the area analysed, given as FeO, is 8.6%.

In sample B a set of coarse metal grains is oriented along one of the crystallographic planes of the enstatite and the areas immediately adjacent to the coarsest grains are relatively free of metal (B1, Table 1). The original FeO content of the grain, obtained by broad beam analysis, is 9.3% (B2 in Table 1). Glass inclusions are present, but are too small to be analysed. The metal (B3, Table 2) has higher Cr and lower Ni contents than the metal within Sample A.

Sample C (60×80 μm) consists of a fine-grained intergrowth of metal, enstatite, glass and sulphide, surrounded by clear enstatite (Fig. 1*c*). The reduction process was accompanied by a significant degree of melting followed by crystallization of clear enstatite (Fig. 1*d*). Broad beam analyses of optically metal-poor areas within the intergrowth (C1, Table 1) reveal a high FeO content (17.3%) in spite of only a slightly high total

† Also S (0.35%).

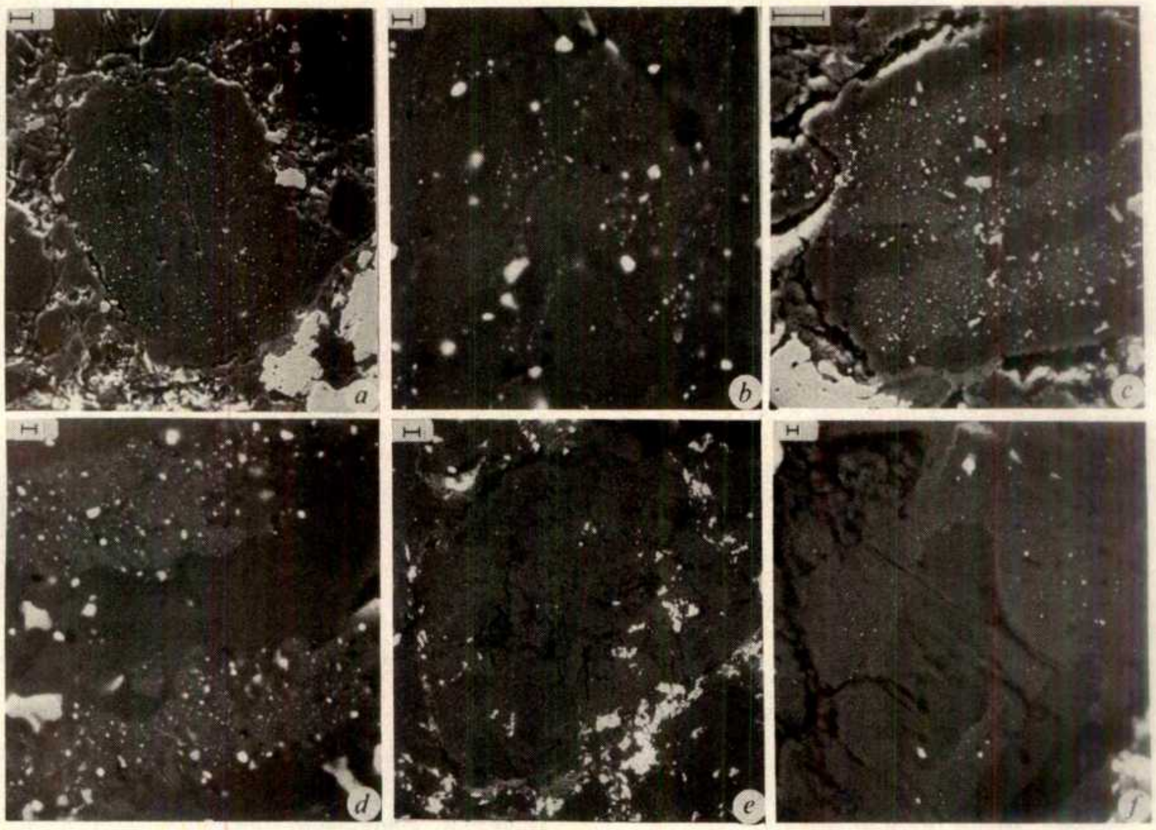

Fig. 1 *a*, A 80 × 120 μm grain of black enstatite (sample A) in Qingzhen, containing inclusions of Ni-poor metal, oriented subparallel to the crystallographic planes of the mineral. *b*, Enlargement of a portion of sample A, showing clustering and coalescing of the metallic particles. SiO_2-rich glass inclusions (dark gray) are also visible. *c*, Sample C (60 × 80 μm) consists of fine-grained intergrowth of metal, enstatite, glass and sulphide, surrounded by inclusion-free enstatite. *d*, Enlargement of sample C, showing textural evidence that melting has occurred. *e*, A 150 × 200 μm chondrule fragment (sample D) consisting of enstatite (light grey) and tridymite (dark grey). *f*, An enlargement of a portion of sample D showing that the enstatite contains sub-micrometre inclusions of metal and vugs. Metal and vug-free enstatite (medium grey) has crystallized in the interior of SiO_2-rich glass areas. Scale bars: *a*, *c*, *e*, 10 μm; *b*, *d*, *f*, 1 μm.

(101.92%). The clear enstatite (C2) has a low FeO content and is Cr_2O_3- and CaO-free. Droplets of glass of prevalently albitic composition (C3, Fig. 1*d*) have segregated into the clear enstatite, suggesting the presence of a feldspathic component within the metal-rich intergrowth. Most metal is Ni-poor (C4, Table 2), but a few grains of Ni-rich metal have been found (C5) indicating that some metal was originally present within the precursor assemblage.

Sample E is a 150 × 200 μm chondrule fragment consisting of enstatite and tridymite in an approximately 1 : 1 ratio (Fig. 1*e*). The enstatite crystals contain sparse sub-micrometre metal inclusions and abundant vugs (Fig. 1*f*) suggesting loss of a volatile component during chondrule formation. SiO_2-rich glass included within the pyroxene is coated with clear enstatite which is vug-free (Fig. 1*f*). The enstatite has a high FeO content (7.6%) and contains significant amounts of Al_2O_3, Cr_2O_3 and CaO (D1, Table 1). This is the highest FeO content ever reported in pyroxenes from enstatite chondrites. It is about 10 times higher than the FeO content of enstatite within 'reduced' chondrules of Qingzhen. The clear enstatite is FeO-poor and Al_2O_3- and Cr_2O_3-free (D2) and the tridymite contains only minor amounts of FeO (D3). The metallic inclusions within the enstatite are too small to be analyzed, but metal grains, interstitial among enstatite and tridymite, are Ni-rich (D4, Table 2). The high FeO content of the enstatite, and the small number of metal inclusions strongly suggest that only minor reduction has occurred within this chondrule.

Qingzhen also contains a population of porphyritic chondrules containing grains of olivine with micron-size inclusions of metal[10,11]. The metal is Ni-poor and was probably produced by *in situ* reduction of the fayalitic (Fe_2SiO_4) component of the olivine[12]. The original fayalitic content of the grains (15–25 mol %) is inconsistent with the composition of materials formed under strongly reducing conditions.

Table 2 Chromium and Ni content of metal within matrix and oxidized components in Qingzhen (in weight %)

	Matrix	A4	B3	C4	C5	D4
Cr	<0.05	1.94	4.4	0.96	0.50	0.50
Ni	3.4	0.95	0.60	1.02	4.1	5.4

Ni-poor metal might represent the condensation product of Fe vapour produced during shock reheating and introduced within the enstatite grains along cracks and crystallographic planes (D. W. Sears, personal communication). As discussed by Sears[13,14], the vapour to form first when Fe, Ni alloy is evaporated is Ni-free because of the lesser volatility of Ni. As shown in Table 2, the Ni-poor metal contains substantial amounts of Cr, while the matrix metal is Cr-free. Therefore, evaporation of the latter could not produce a Cr-rich vapour. Furthermore, the metallic inclusions occur within enstatite grains which in most cases still retain FeO contents significantly higher than the 'reduced' enstatite in the surrounding matrix and chondrules. Incomplete reduction of precursor oxidized silicates appears to be the only possible mode of formation of the Ni-poor metal.

The observed range of FeO contents in the ferromagnesian silicates of Qingzhen (0.15–7.6%) represents a lower limit, because reduction has occurred. The highest calculated FeO content is 18% for relict olivines inside incompletely melted chondrules. Even though the bulk of the Qingzhen meteorite is highly reduced, such high ranges of FeO contents are comparable to those observed in highly unequilibrated ordinary chondrites.

We exclude the possibility that the oxidized components in Qingzhen were introduced during collision with a more oxidized body and subsequently reduced. These components occur as single grains or chondrules surrounded by highly reduced material, not as xenolithic clasts. Furthermore, the presence of FeO-rich enstatite in chondrule interiors indicates that these components were already present prior to or during the process of chondrule formation, and therefore long before the accretional event that culminated with the formation of the parent body of Qingzhen.

Various reheating mechanisms could have triggered the reduction process and the melting (often incomplete) of these oxidized components. Reheating during shock is a possibility. Wang and Xie[15] describe some features in Qingzhen which are suggestive of shock. But shock features are absent in the coarse grained sulphide minerals in the matrix, which are always monocrystalline, and not polycrystalline as one would expect had they been shocked (A. El Goresy, personal communication). Thermal metamorphism in the parent body interior is another possibility. This process, which is recorded in the texture and chemistry of ordinary chondrites of increasing petrologic type, brings about mineral recrystallization and equilibration leading ultimately to mineral phases with uniform FeO/(FeO/MgO) ratios. But thermal metamorphism cannot be responsible for the reduction of the oxidized components in Qingzhen for the following reasons: (1) Qingzhen is highly unequilibrated and contains neither the textural nor the chemical evidence of metamorphic processes; (2) in many cases the grains were accompanied by melting, while the bulk of Qingzhen was never melted.

Thus, a reheating event outside the parent body is required, leaving the chondrule formation process as the only plausible alternative. It has been recently shown that this process may lead to incomplete melting of chondrule precursor assemblages and reduction during chondrule formation has been well documented in highly unequilibrated ordinary chondrites[2,12,16]. We suggest that oxidized ferromagnesian silicates occurring either isolated or as clusters of grains were reheated and melted to various degrees during the chondrule formation event that produced the main population of highly reduced chondrules in Qingzhen.

The less reducing nebular conditions required for the stability of the oxidized components found in Qingzhen could be obtained by assuming local fluctuations in the degree of reduction of the nebular gas possibly related to inhomogeneous admixture of a reducing component.

It has been recently suggested that the onset of the reducing conditions required for the formation of enstatite chondrites may be produced by loss of O-bearing compounds, in the form of high temperature condensates (refractory compounds of Ca, Al and Ti)[14], or by a process of dust-gas fractionation followed by evaporation and condensation in the dust-(and O) depleted nebular region[17]. According to these models, failure of the residual solids to equilibrate with the nebular gas or incomplete evaporation of solids in the dust-depleted region, could allow the preservation of oxidized material. Alternatively, the oxidized components found in Qingzhen might represent materials originated in dust-enriched nebular regions[17], which were subsequently transported into an adjacent more reducing environment.

We thank D. Wang for making samples of the Qingzhen meteorite available. The work described in this paper was carried out at the Jet Propulsion Laboratory, California Institute of Technology, under contract with the National Aeronautics and Space Administration.

Presence of a superparamagnetic component in the Orgueil meteorite

Thomas J. Wdowiak & David G. Agresti

Department of Physics, University of Alabama in Birmingham,
Birmingham, Alabama 35294, USA

The Orgueil CI carbonaceous chondrite meteorite fall of 14 May 1864 is of particular interest because of the presence of an organic component which included amino acids. Using Mössbauer spectroscopy, we have determined that the Orgueil meteorite contains an appreciable fraction of its iron in the superparamagnetic state. This result implies that the superparamagnetic iron component was formed during an aqueous phase in the history of the parent body, and that the superparamagnetic component may have served as a catalyst for formation of the organic component.

A 52.4-mg sample from the Smithsonian National collection (Orgueil USNM-234) was ground into a powder and dispersed into 78.4 mg of molten parafin. On cooling, the parafin was moulded, while plastic, into a 6-mm diameter pellet that was then supported by a 25-mm lead annulus. The sample was cooled to temperatures between 21 and 295 K by transferring heat by gaseous helium from the sample to an Air Products closed-cycle refrigerator. This method of heat transfer was used to prevent mechanical vibration of the sample by the closed-cycle refrigerator. The Mössbauer spectrometer employs a liquid-nitrogen cooled Si(Li) detector for the 14.4-keV ^{57}Fe γ rays.

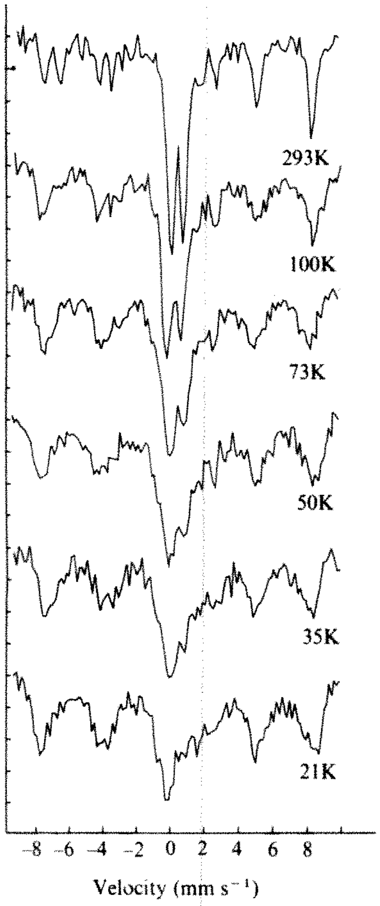

Fig. 1 Mössbauer spectra of the Orgueil CI carbonaceous chondrite. The 293 K spectrum shows the presence of ferromagnetic magnetite and two paramagnetic absorptions near 0 mm s^{-1}. Spectra obtained below the Verwey transition at 119–116 K, at 100 K, 73 K, 50 K, 35 K and 21 K show a gradual diminishing of the paramagnetic absorption and enhancement of the ferromagnetic absorptions indicating the presence of a superparamagnetic magnetite component.

A spectrum was obtained at 295 K in order to characterize the sample. This spectrum, similar to that obtained by Gerard and Delmelle[1], shows a blending of paramagnetic features with the ferromagnetic spectrum of magnetite[2]. Subsequent measurements were made at temperatures of 100, 73, 50, 35, and 21 K. This range is below the Verwey transition that occurs in Fe_3O_4 between 119 and 116 K, and was chosen because previous studies[3] have shown that the Fe_3O_4 ferromagnetic spectrum does not alter between 100 and 7 K. Each spectral measurement required ~5 days of counting because of sample size and source strength. The spectra obtained between 100 and 21 K show the same gradual diminishing of the paramagnetic absorptions and enhancement of the ferromagnetic features as observed for superparamagnetic materials where the particles are of subdomain size[4–6].

Such particles are in a state of uniform magnetization with a net magnetic moment possibly 10^5 times that of a single atom (hence 'superparamagnetic'). For sufficiently small particles at higher temperatures, the relaxation time of the magnetic moments of these particles is smaller than the nuclear Larmor precession time, and the Zeeman splitting collapses to the two-peak spectrum characteristic of the paramagnetic state[5]. As temperature decreases for a given particle size, the relaxation time increases to the point where the Zeeman splitting can be observed (ferromagnetic state). When a distribution of subdomain particles exists, as is usual, that distribution can be determined from the Mössbauer spectrum[4,5]. We plan to carry out such determinations in the future. By taking the ratio of the integrated paramagnetic iron absorption between 100 and 21 K and the total integrated absorption of all forms of iron, we estimate that ~30% of the iron of the meteorite is in the superparamagnetic subdomain form. The remaining iron is ~45% ferromagnetic and 25% paramagnetic. The magnetite is thus ~40% superparamagnetic and 60% ferromagnetic. Characteristically, superparamagnetic particles are <300 Å in size, which indicates that the Orgueil contains an appreciable portion of iron as Fe_3O_4 in this size range. The magnetite content of the Orgueil meteorite has been determined using the Faraday balance and the vibrating sample magnetometer to 11.0 ± 0.4 wt% (ref. 7). Combined with the present results, this suggests the superparamagnetic magnetite component is ~4.5 wt%.

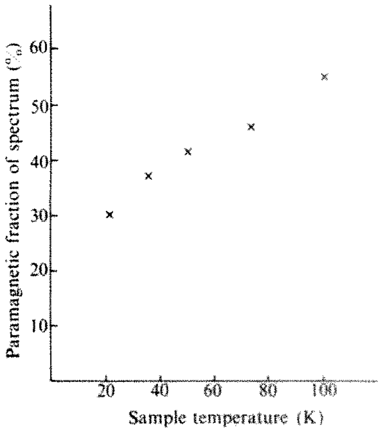

Fig. 2 Paramagnetic fraction of spectrum versus sample temperature. The decrease between 100 and 21 K indicates the superparamagnetic magnetite component held by ~30% of all iron.

The presence of a superparamagnetic component in the Orgueil meteorite requires a discussion of its origin and its impact on the origin of the organic component. Particles having sizes in the <300 Å range are almost certainly not the result of size reduction processes. Superparamagnetic particles can be produced by precipitation from aqueous solutions[5], vapour condensation[8], and crystallization from a melt[6]. The last mechanism is unlikely for a CI carbonaceous chondrite such as the Orgueil. There is evidence for aqueous activity in the parent body of the Orgueil meteorite[9–11], as well as those of other carbonaceous chondrites. The magnetite superparamagnetic particles could be the result of precipitation from an aqueous solution or they may be a secondary product arising from the oxidation of iron sulphides in aqueous conditions, although oxidation in the solar nebula is also a possibility[7].

While aqueous processes are those most likely to be responsible for the superparamagnetic magnetite component of the Orgueil meteorite, either directly through precipitation or indirectly through oxidation of iron sulphide, an alternate hypothesis for superparamagnetic particles has been put forward by Cameron[12]. He argued that superparamagnetic magnetite relict cores of interstellar grains, such as proposed by Jones and Spitzer[13], might be found in carbonaceous chrondites of type I. This hypothesis needs to be re-examined in the light of the result presented here. It may be that the Orgueil superparamagnetic component is a solar nebula analogue to interstellar grain cores.

The possibility that catalytic activity of magnetite in meteorites and in the solar nebula is responsible for meteorite organics has been reviewed by Anders *et al.*[14]. The organic component of the Orgueil includes amino acids[15], fatty acids[16], alkanes[14], heterocyclics[17], and polymeric material[18]. Nickel–silica catalysts prepared by coprecipitation and exhibiting superparamagnetic properties[19,20] are utilized in laboratory and industrial organic synthesis. A superparamagnetic magnetite component would thus be an attractive candidate as a catalyst for the formation of organics in the Orgueil meteorite.

A preliminary examination of bulk samples and separated magnetic fractions of the Allende meteorite has not revealed any superparamagnetism in the iron minerals. The bulk of the iron was paramagnetic and only a small separated fraction exhibited ferromagnetism. Sears and Marshall[21] have pointed out that while Mössbauer spectroscopy does not reveal magnetite in the Tieschitz unequilibrated ordinary chondrite[22], X-ray diffraction indicates its presence. The difference between those results may be due to the magnetite in the Tieschitz being entirely superparamagnetic, and hence not appearing in the expected ferromagnetic absorption pattern of a 293 K Mössbauer measurement, while X-ray diffraction would show the lattice structure of particles ≪300 Å in size. This question, coupled with the results of our preliminary examination of the Orgueil meteorite at a range of cryogenic temperatures, suggests that the Mössbauer technique has broader applications in meteoritics than previous studies have indicated.

We thank Roy Clarke Jr for assistance in obtaining the Orgueil meteorite sample and acknowledge the Graduate School of the University of Alabama in Birmingham for its support.

The ability of small molecules to form clathrate hydrates of structure II

D. W. Davidson, Y. P. Handa, C. I. Ratcliffe & J. S. Tse

Division of Chemistry, National Research Council of Canada,

Atomic Energy of Canada Limited, Chalk River Nuclear
Laboratories, Chalk River, Ontario, Canada K0J 1J0

Since gas hydrates were shown in the mid-1950s[1] to be water clathrates of two distinct crystallographic structures (Table 1), it has been generally accepted that structure I hydrates are formed by molecules with maximum van der Waals diameters of up to about 5.8 Å while structure II hydrates are formed by larger molecules, up to about 7.0 Å in size. No exception to this general rule has been observed among more than 100 individual species of molecules known to form clathrate hydrates[2,3]. From X-ray and neutron diffraction studies we now find, however, that the two smallest molecules which form clathrate hydrates—argon and krypton—do so in the structure II modification. This finding supports a suggestion of Holder and Manganiello[4].

One of the reasons for the shortage of crystallographic data for gas hydrates of small guest molecules is because such hydrates are stable near 0 °C only at relatively high pressures.

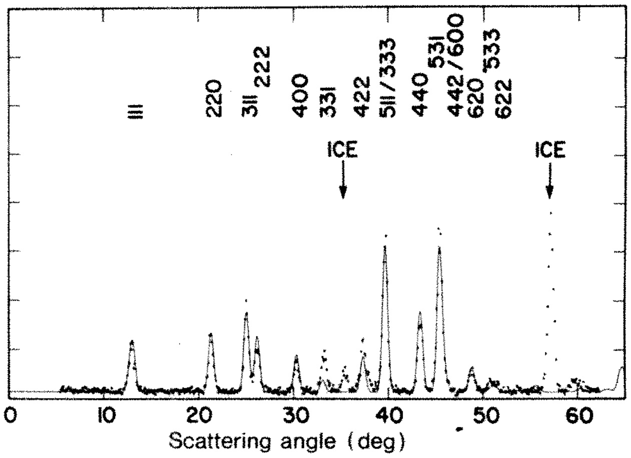

Fig. 1 Comparison of the observed (points) and fitted neutron scattering profile of krypton deuteriohydrate at 5.7 K.

Powder diffraction patterns, however, may be recorded at low temperatures (≤100 K) without appreciable hydrate decomposition. For the X-ray and neutron diffraction studies described here, powdered samples were prepared by grinding H_2O or D_2O ice in a rotating rod mill at −30 °C for several days under gas pressures (2 MPa for Kr and CH_4, 10 MPa for Ar) twice as high as required for hydrate stability.

X-ray powder photographs of Ar and Kr hydrate samples were taken with MoK_α radiation, as previously described[5]. Lines were readily indexed in the structure II cubic Fd3m space group, with observed intensities in good agreement with structure factor calculations which assumed full occupancy of the 12- and 16-hedral cages.

Elastic neutron scattering measurements on Kr and CH_4 D_2O hydrates were made on the C5 spectrometer operated in a two-axis mode at the NRU reactor, Chalk River. The monochromator was Si(111) and the neutron wavelength 2.22374 Å. A sapphire filter in the incident beam and a Si(111) analyser set for elastic scattering were used to reduce the background. The powder diffraction profile of Kr deuteriohydrate at 5.7 K is shown in Fig. 1. Except for two peaks from hexagonal ice the observed peaks are indexed on the basis of space group Fd3m. No peaks from structure I were observed. Integrated intensities were fitted to a structure II hydrate lattice, with all cages filled and zero thermal parameters for O and D. Because of the limited range of scattering angle, the fit was not very sensitive to these two assumptions.

The results are summarized in Table 2. The lattice parameters *a* found for Ar and Kr hydrates at 100 K are similar to those found for other structure II hydrates[5,6], which average less than 0.1 Å larger at comparable temperatures. Methane hydrate is established as structure I. In the hydrates of N_2 and O_2, which require higher pressures for stability than any other known hydrate[7], the guest molecules are smaller than methane: the structures of these hydrates must now be considered uncertain.

Except for small compressibility effects, the ideal solid–solution theory of clathrate hydrates[8] gives for the chemical potentials of water molecules in structures I and II

$$\mu(\mathrm{I}) = \mu^0(\mathrm{I}) - \frac{kT}{23}[\ln\{1 + C_\mathrm{S}(\mathrm{I})P\} + 3\ln\{1 + C_\mathrm{L}(\mathrm{I})P\}]$$

$$\mu(\mathrm{II}) = \mu^0(\mathrm{II}) - \frac{kT}{17}[2\ln\{1 + C_\mathrm{S}(\mathrm{II})P\} + \ln\{1 + C_\mathrm{L}(\mathrm{II})P\}]$$

where μ^0 refers to water in the hypothetical empty lattice, C_S is the Langmuir constant which relates the extent of occupancy by the gas of the small 12-hedral cages to the pressure P (strictly, the fugacity) of the hydrate-forming gas, and $C_\mathrm{L}(\mathrm{I})$, $C_\mathrm{L}(\mathrm{II})$ are corresponding Langmuir constants for the 14- and 16-hedra. The 12-hedra being similar in the two structures, $C_\mathrm{S}(\mathrm{I}) \sim C_\mathrm{S}(\mathrm{II})$.

‡ Ref. 12.

The lowest gas pressure P_0 at which a hydrate can exist is the pressure which lowers its chemical potential to that of ice or liquid water at the same temperature: whether structure I or structure II is stabler depends on which has the smaller value of P_0. Although accurate values of μ^0 are not known, $\mu^0(\mathrm{II}) < \mu^0(\mathrm{I})$ because of the greater similarity to ice of the hydrogen bonding between the water molecules in the structure II lattice[2].

For relatively large guest molecules (M) structure II is more stable because $C_L(\mathrm{II}) \gg C_S$, $C_L(\mathrm{I})$, only the 16-hedra are occupied by M molecules, and the compositions approach $M\cdot 17H_2O$. For very small guest molecules, on the other hand, structure II stability results from the condition $C_S > C_L(\mathrm{I})$, $C_L(\mathrm{II})$, that is, from a preference for the small cages, and the composition is much different, about $M\cdot 6H_2O$. Structure I will generally be preferred when $C_L(\mathrm{I}) > C_S$, $C_L(\mathrm{II})$ or $C_L(\mathrm{I}) \approx C_S > C_L(\mathrm{II})$. The former condition appears to apply to most structure I hydrates since even for a guest molecule as small as Xe (Table 2) NMR studies have shown[9] that $C_L(\mathrm{I})$ is an order of magnitude larger than C_S near 0 °C.

The limited success of past calculations of hydrate dissociation pressures from assumed intermolecular potentials[2,8,10] now appears to be due, at least in part, to the erroneous assignment of structure I to the model hydrates of argon and krypton. Accurate experimental determination of the compositions of Ar and Kr hydrates should prove of importance in the evaluation of $\mu^0(\mathrm{II})$. Values of $C_S(\mathrm{II})$ for Ar and Kr in the double hydrates of $CHCl_3$ have already been measured by Barrer and Edge[11].

This manuscript is issued as NRCC no. 23110.

Reflected turbidity currents on an Ordovician basin floor, Canadian Appalachians

R. N. Hiscott* & K. T. Pickering†

Sedimentary structures associated with turbidity current deposits show either partial or complete Bouma T_{a-e} sequences[1] that suggest deposition of sediment from a waning (decelerating) unidirectional flow[2]. Bathymetric highs and basin margins can cause turbidity currents to reflect back along their original flow paths, a rare situation in both ancient[3,4] and modern[5] marine basins. The internal structures of such contained, or reflected, turbidites have only been described in one case, the Contessa bed (ref. 4 pp. 268, 300). Our data from 1–6-m thick graded, mud-dominated turbidites from the Quebec Appalachians, using mainly sole marks, megaripple, ripple and grain fabric data, suggest that during the deposition of these beds the turbidity currents were reflected several times from either internal basin highs or basin slopes. The recognition of such beds not only provides an insight into the depositional environment (deep-water basin floor), but also allows detailed bed-by-bed correlations over tens of kilometres of coastal sections since the beds are reliable chronostratigraphical datum lines.

The beds form part of the 1.5-km thick $\beta 1$ and $\beta 2$ members of the Middle Ordovician Cloridorme Formation[6], a flysch unit deposited in a constricted foreland basin during the Taconic Orogeny[7]. The $\beta 1$ and $\beta 2$ sequence consists of thinly-bedded classic turbidites and hemipelagic shales, punctuated about every 10 m by a thick bipartite bed consisting of a lower, graded sandstone (1/4) and a texturally homogeneous, structureless, silty mudstone cap (3/4). These beds range in thickness from 1 to 5.5 m, and can easily be correlated with little apparent thickness change between localities 25 km apart.

Most beds have basal flute casts that indicate flow from east to west. This led earlier workers[8] to interpret the beds as deposits of unusual, unidirectional turbidity currents. Internal sedimentary structures consist of parallel lamination, cross-lamination, small-scale megaripple and ripple forms, climbing ripple lamination, wavy and convolute lamination, and pseudonodules[8]. Grading in the lower sandstone part is not continuous, but is punctuated by mud-draped partings across which grain size may decrease abruptly. Between these grain-size breaks, or muddy

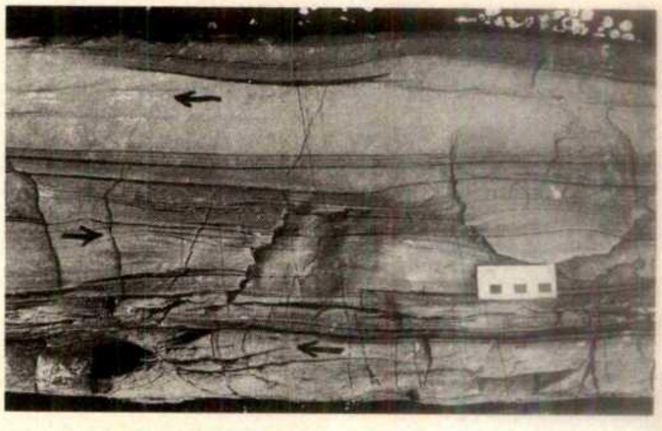

Fig. 1 Sandstone divisions deposited by a reflected turbidity current. The sandstone part of the turbidite is ~30 cm thick. The mudstone cap (not shown) is 105 cm thick (bed PF-2, Fig. 2). Arrows indicate flow directions through the bed.

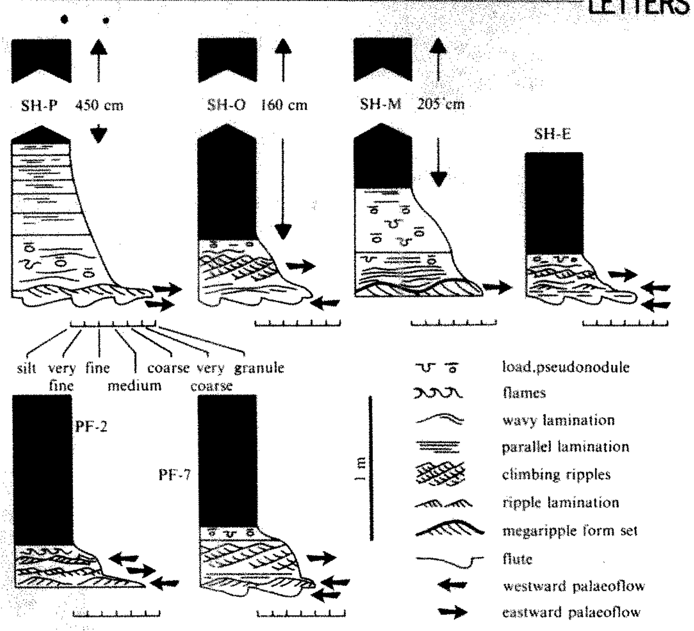

Fig. 2 Sketches of six beds deposited by reflected flows. Structures are accurately drawn to show observed eastward or westward flow.

partings, sedimentary structures or grain imbrication indicate flow from either east to west, or from west to east, with measured palaeoflow azimuths frequently 160°–180° opposed to one another in the same bed (Fig. 1). At the top of the sandy part of a few beds, alternating divisions of muddy lamination and pseudonodules may repeat several times, each couplet being finer and thinner than the one below. The uppermost sandy division, in all beds, consists of pseudonodules. Sketches of the internal features of six beds appear in Fig. 2. We have observed about 50 such beds in members $\beta 1$ and $\beta 2$.

The form set of cross-stratification at the base of bed SH-M (Fig. 2) has been interpreted as the deposit of antidunes migrating upcurrent[9,10], due to the 180° difference between; (1) cross-bed dip direction; and (2) palaeoflow direction indicated by flute casts in surrounding beds. Our discovery of both eastward and westward palaeoflows in single beds removes the original impetus for the antidune hypothesis. In addition, the grain fabric of the cross-strata[11] indicates that the depositing current flowed from west to east, opposite to the direction required by the antidune hypothesis. We interpret this form set, therefore, as a mud-draped megaripple train; the megaripples were migrating from west to east.

Each graded bed was deposited by a large volume turbidity current. The thick, poorly-graded mudstone caps suggest flows with enormous amounts of entrained mud. Despite the palaeoflow reversals in the sandy parts of beds, deposition was rapid. as suggested by both abundant climbing ripples and loading (pseudonodules).

We explain the details of sedimentation of these beds as follows (Fig. 3). The large-volume, mud-rich flows were generated along steep, tectonically-formed slopes on the south side of the foreland basin[6]. On reaching the base of the slope, the powerful flows were constrained to flow westward into the area where our sections are now located; most flutes were eroded by this first westward pass of the current. The lowest sand division was either deposited by the initial westward-flowing current, or by the first return flow. There is often a sharp grain-size break above the lower division, followed by a thin mud drape. We believe this sequence indicates: (1) deposition of a coarse basal division; (2) passage of the main flow across the basin floor; (3) suspension fallout of mud from thick, residual, suspended-sediment cloud; and (4) return of the reflected current to deposit the next sandy division. The return flow was always less competent than the first westward flow, due to frictional energy losses and loss of sediment load and, therefore, transported sand significantly finer than that in the lower division (Fig. 2).

Fig. 3 Depositional model and a representative structure sequence for contained, reflected flows. The length of east–west arrows indicate relative current speeds as the flow decelerates. See Fig. 2 for key.

Several beds have a basal division of coarse to granule grade sand with a fabric or sedimentary structures indicating eastward sediment transport. Included in this category is the bed with basal megaripple cross-stratification (bed SH-M, Fig. 2). These coarse divisions are better sorted than overlying sand, and may not have been deposited entirely by the first reflected current. The sand, due to its coarse grain size, was probably deposited by the initial westward-flowing current, and later reworked as bedload beneath the first reflected flow.

After sand deposition, the ponded, residual, silt-mud suspension was probably still moving slowly back and forth across the basin floor, gradually losing momentum. We believe that it was at this time that the fine-grained pseudonodule divisions were deposited. The silt was deposited quickly, leading to extensive loading and disruption of lamination by liquefaction. In the case of the largest flows (bed SH-P, Fig. 2), the periodic, decaying oscillation of the current led to the deposition of alternating laminated (current deposited) and pseudonoduled (liquefied) layers of decreasing thickness.

The final phase of sedimentation was the fallout of mud from the ponded suspension to form a thick, homogeneous, mudstone cap. The concentrated mud cloud deposited rapidly, perhaps in the same way that shelf muds are rapidly deposited in areas of high concentration, regardless of the competence of local currents[12]. Lack of grading in the caps is also consistent with rapid deposition. Clay minerals probably formed particle aggregates (flocs) that settled much more quickly than single particles.

Unlike Bouma-type turbidites, these contained, or reflected, turbidites do not have a predictable sequence of internal sedimentary structures. In particular, ripple lamination, wavy lamination, convolution, pseudonodules and parallel lamination may alternate in an unpredictable way in the upper division of the sandstone part of these beds. Flow direction in these divisions may change one or more times up through a single bed. For each bed, the exact details of deposition depend on: (1) the importance of flow reflection; (2) the distance that the flow travelled before returning to deposit more sediment; and (3) the importance of interference and collisions between separated parts (offspring) of the single primary flow (parent) that could be moving along different paths and, perhaps, overriding one another because of density differences.

Contained, reflected turbidites can, with care, be distinguished from classic Bouma-type turbidites, based primarily on palaeoflow reversals and thick mudstone caps produced by ponding of the residual mud-silt cloud[3]. These unusual beds are widespread, and provide compelling evidence for deposition in a confined basin. Contained turbidites have only been described from deep-sea sediments, but thinner and perhaps finer-grained examples should also be expected in turbidite sequences of glacial or alpine lakes and arctic fjords with suitable geometry.

Sampling strategy for stable carbon isotope analysis of tree rings in pine

Steven W. Leavitt & Austin Long

Department of Geosciences, University of Arizona,
Tuscon, Arizona 85721, USA

Stable carbon isotope measurements in tree rings have been explored as potential indicators of past climate[1,2], and as proxy data for reconstructions of the history of $^{13}C/^{12}C$ variations of atmospheric carbon dioxide as related to the global carbon cycle[3–6]. Results of these studies are often conflicting, perhaps partly due to the limited style of sampling natural systems with large inherent spatial variability. We have examined stable carbon isotopic trends in tree rings among several radii of the same tree (*Pinus edulis* Engelm.) and among several trees from the same site, to determine the extent of this variability. The circumferential range in $\delta^{13}C$ values of cellulose is ~1–1.5‰, whereas among individuals it is ~2–3‰. Tests to determine how well various combinations of cores fit the trend of an individual tree or of the site as a whole indicate that pooling four cores from four trees accurately represent site $\delta^{13}C$ trends and absolute values.

Whereas dendroclimatological studies commonly sample several tens of trees at each site with two cores per tree[7], the time and expense of carbon isotopic analysis precludes such density of sampling at each site, and often limits analysis to groups of years rather than individual years. The potential weaknesses of single radius (or core) sampling in isotopic studies was revealed by the $\delta^{13}C$ results of Tans and Mook[8] for two radii of the same *Quercus rubra* L. cross-section which showed not only different isotopic trends but up to 4‰ differences between corresponding rings. The factors which influence carbon isotopic fractionation in trees have already been addressed in models such as that of Francey and Farquhar[9]. However, the patterns and magnitude of this fractionation in natural settings have not been discussed in such detail. To test for circumferential variability we obtained two cross-sections from a pinyon pine tree (*Pinus edulis* Engelm.) located at a site 30 km south of Flagstaff, Arizona, cut at the end of the 1981 growing season. To test for intrasite variability we collected cores from eight other *P. edulis* individuals from the same site at the end of the 1982 growing season.

The wood materials were dated at the Laboratory of Tree-Ring Research of the University of Arizona. One cross-section was divided into eight equally spaced radii which were cut out as 'cores' 5 mm wide. The rings were separated into 5-yr groups from 1900–04 to 1975–79, plus 1980–81 for the cross-section samples and 1980–82 for the cores. The ring intervals from the second cross-section were milled from the full circumference. The cellulose (holocellulose) component of the wood was isolated in a method modified after Green[10] (details of preparation and analysis are given in refs 5, 11). The $^{13}C/^{12}C$ isotopic ratios are expressed with respect to the international PDB standard[12]. Overall reproducibility, including sample preparation, combustion and mass-spectrometric analysis, is estimated to be ~0.1‰.

Several studies have reported on circumferential $\delta^{13}C$ variability in leaves[11,13,14] and rings[3,6,8,13,15,16–18]. Despite a variety of species and localities, the range of $\delta^{13}C$ around the circumference of tree rings is typically 1–2‰. Except for the Tans and Mook[8] results, the isotopic trend from a single core has generally been found to parallel that of others, even though absolute values may differ. From the standpoint of practical sampling and efficiency of analysis, the relevant question is what minimum number of cores from a single tree is required to represent

accurately the $\delta^{13}C$ of cellulose fixed in a tree-ring sequence, although the answer may actually differ among species and local environments.

The *P. edulis* cross-sections we used to help resolve this question for one environment had nearly circular, concentric rings. Furthermore, the ring series had only 1.5% missing rings over the growth period 1795–1981. Figure 1 shows the comparison between the $\delta^{13}C$ trends of the eight radial slices (simulating cores) and 'whole-ring' trend derived from full-circumference analysis of the adjacent cross-section. The $\delta^{13}C$ differences among radii at any interval range from ~0.5 to 1.2‰.

An assessment of the minimum number of cores needed must involve a compromise between effort involved and proximity to the true value. To evaluate this trade-off, we compared combinations of cores with the full-circumference $\delta^{13}C$ results taken as the true value, using two tests. The Pearson correlation coefficient (r) measures the strength of the linear relationship between mean data of a given core combination and that of the cross-section, and the sum of the squares of the differences (SS) between the mean core combination and the true trend is a measure of the absolute $\delta^{13}C$ differences between the curves.

These tests were performed on selected combinations of 1–8 radii. Sampling of a given number of cores from a tree in the field would normally be done equidistantly about the tree circumference, and it is these combinations which were examined. For the eight radii of this study at 45° intervals, equidistant combinations of 2, 4 and 8 cores exist. For combinations of three, five, six and seven cores, however, equidistance could only be approximated with this set of cores. The lowest r found was 0.84 for a single radius (west) versus the true values, yet it is actually significant at 99%. However, close examination of such $\delta^{13}C$ trends with relatively low r values reveals significant differences between some of the short-term variations of the core trend and the true trend. This would limit reconstruction of fine-scale features with single cores. Both parameters improve greatly as the number of cores increases from one to four ($\bar{r}$ increases from 0.89 to 0.96 and $\overline{SS}$ decreases from 1.54 to 0.47), but beyond four cores the improvement tails off. Two cores show a marked improvement over single cores in that not only are the correlation coefficients of each two core combination >0.90, but the largest SS values are only slightly >1. SS values of <1 indicate the mean deviation between core combination and true trend at each interval is <0.25‰, close to a non-statistical difference in light of analytical precision.

We performed this statistical analysis using (1) unweighted $\delta^{13}C$ means of the core combinations, and (2) $\delta^{13}C$ means of the core combinations weighted for the respective 5-yr ring thickness contribution of each of the selected cores, and found the results to be nearly identical, despite two- to threefold differences in ring thickness among radii for a given interval. This implies that, in application, cores may be pooled before analysis (equivalent to weighting the mean) and the results will not be distinguishable from the much more involved process of analysing each core separately and calculating a mean (equivalent to the unweighted mean). We had also tested the eight possible combinations of four cores from the same side of the tree and found they show an appreciably higher SS ($\overline{SS}=0.62$, range 0.42–0.74) than those taken from opposite directions ($\overline{SS}=0.35$, range 0.19–0.51), which suggests that orthogonal cores yield more representative samples. Based on these results we are now sampling four cores per tree wherever possible, because they represent short-term variations well and they offer an extra margin of safety over two cores.

Adequate representation of a $\delta^{13}C$ trend from a given locality requires a knowledge of the $\delta^{13}C$ variability among individuals. Very few studies have examined intra-site variation of $\delta^{13}C$ in tree rings, with results in the general range of 1–2‰ (refs 3, 6, 16, 18, 19). Unfortunately, single cores were generally taken as representative of each tree in these studies. Our study compares δ^{13}C trends in eight trees from a single site sampled with four orthogonal cores per tree. These trees were within an area of ~2 ha of an open pinyon–juniper woodland with typical distances of 5–10 m between individuals. The goal was not to sample eight identical trees, but to sample eight trees having no obvious characteristics which would disqualify them in routine sampling. The physical setting was uniform in that the terrane was nearly flat or sloping slightly WNW, and the soil was developed on basalt bedrock. We selected pinyons of apparent good health although each had a different canopy configuration. The heights of the sampled trees ranged from 5 to 7 m, the diameters (1 m above ground) were ~20–45 cm, and the ages varied from ~130 to 300 yr. For each tree, 5-yr ring groups from the four cores were combined before chemical preparation and analysis.

Figure 2 shows the δ^{13}C trends from these eight trees and the mean trend. The δ^{13}C values for each time interval range over 2.5‰ among the trees. If not for the one tree which shows distinctly heavy isotopic values, the range would be more of the order of 1.5‰. We found no relationship between the absolute δ^{13}C values of the trends and the respective ages, heights, diameters, crown shapes, or proximity to neighbours of the trees.

As in the case of the radial results, it is important to determine how many trees would be required to give an accurate representation of both the δ^{13}C trend and absolute δ^{13}C values registered in the trees of the site. No absolute reference value exists for comparison, so we have used the mean of the eight trees as the true value. The unweighted mean seems logical as there is no *a priori* reason to suspect that any one tree is a more reliable recorder than the next. It was also necessary to examine many more combinations of individuals in the site test than in the circumferential test in order to simulate all field collection possibilities.

The δ values of each tree were first weighted for their respective mean 5-yr group ring widths, which typically varied 3-to 4-fold among trees, before calculating the mean trend of each combination of trees. This is equivalent to pooling trees before analysis. The pattern of r and SS results is similar to those from the intra-tree analysis, although due to the wider range in δ^{13}C values among the trees, the SS values are higher. As in the intra-tree analysis, it appears possible for a single tree to be highly representative of the site (high r, low SS), but in the mean ($\bar{r} = 0.91$, $\overline{SS} = 8.51$) and extreme, individual trees will be much less representative than larger combinations. Sampling four trees per site yields highly significant r values ($\bar{r} = 0.98$) and low SS ($\overline{SS} = 0.80$), making it a good choice for practical application. The diminishing returns of larger samples may not justify the added sampling expense and energy. We are now collecting cores from six to eight trees per site and choosing four trees with the best dating, fewest missing rings, fewest obscured rings, and so on, for a pooled sample to represent the site δ^{13}C trend. These pooled test results show no significant differences from a similar compilation comparing unweighted means of the selected trees with the true value trend. Furthermore, these results differ little from those of similar tests where we used a weighted (by ring thickness) mean trend of the eight trees as the 'true' trend.

In addition to tree-ring isotope studies for reconstruction of climate and past atmospheric carbon dioxide, these results may be useful in designing and interpreting growth-chamber experiments where environmental effects on δ^{13}C are tested, or to food-web studies where stable isotopic compositions of organic matter are used to determine carbon sources and contributions. However, we must warn against extrapolating circumferential relationships developed from one pinyon pine to all species and environments. In view of the factors influencing δ^{13}C in plants described by Francey and Farquhar[9], microenvironmental factors such as shading may enhance circumferential variability. Perhaps the δ^{13}C differences among radii of any tree may ultimately be used to quantify the microenvironmental differences in the crown which produce the circumferential variability.

Within a site, the range of 2–3‰ among pinyon pine is actually quite similar to other studies with other species, despite their being sampled with single cores and representing site environments often quite distinct from the semi-arid sites in which pinyon commonly occur. This range of δ^{13}C values at a site must be considered in sampling, particularly when attempting to relate the differences in absolute δ^{13}C values among sites to the different climates of the respective sites. We had found such a δ^{13}C-climate relationship in a study with juniper[5], but we had represented the δ^{12}C values of each site with only one tree.

We thank J. Dean and D. Bowden (Laboratory of Tree-Ring Research, University of Arizona) for dating the pinyon pine tree rings. C. Sullivan and M. Leavitt assisted in field sampling, E. Sutherland assisted in mechanical preparation, and L. Warneke helped prepare and analyse the cellulose. This research was supported under the US Department of Energy Carbon Cycle Research Program through Oak Ridge-Martin Marietta Subcontract No. 19X-22290C.

Correlation of Pleistocene glacial and interglacial sediments deposited on land with sediments deposited synchronously in the ocean basins is rarely accomplished[1–3]. A significant exception is the correlation of continental shelf Bay of Biscay interglacial deposits with interglacial sediments from north-east France using δ^{18}O and pollen[4]. In the Arctic Ocean, the definition of a partial magnetic stratigraphy for a Pleistocene sequence on Banks Island, western Arctic Archipelago[5], permits correlation with magnetically defined marine sediment of the Chukchi–Alpha Ridge[6–8] (Fig. 1). We report here the details of this first Arctic Ocean glacial-marine to continental-glacial deposit correlation, and its climatic interpretation. Arctic Ocean sediment texture is climatically controlled and fine-grained textured sediment was deposited in the ocean at the same time as interglacial deposits formed on the adjacent land. The occurrence of coarse-grained Arctic Ocean sediment on the other hand is synchronous with glacial advances on land and also represents periods of deglaciation.

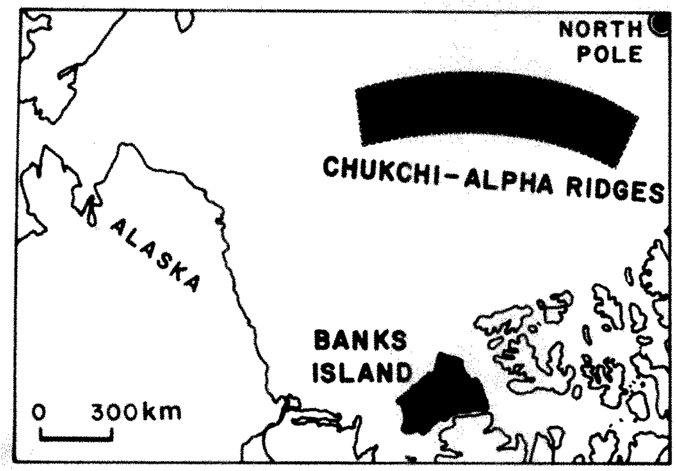

Fig. 1 Location of Banks Island and the area of glacial–marine stratigraphy developed for the Chukchi–Alpha Ridges.

Palaeomagnetic interpretations of Arctic Ocean sediment have been based primarily on polarity signatures (+ or −) published without supporting inclination, intensity or virtual geomagnetic pole (VGP) latitude data[6,9]. However, these data have been discussed recently[8], with inclination data for a representative Arctic core (and similar data for the Banks Island record) (Fig. 2) confirming the validity of previous interpretations. Demagnetization and VGP data have been published for Banks Island[5]. Supporting data on demagnetization, inclination and intensity of the marine cores not considered here, will be published elsewhere[10].

The Bruhnes–Matuyama magnetic boundary, interpreted to be 730 kyr, has been recognized in numerous sediment cores taken from ice-island T-3. The reversal from normal to reversed polarity occurs consistently in stratigraphical unit K[7], which is widely recognized throughout the Amerasian Basin of the Central Arctic Ocean and also reliably correlates with sediment of the Lomonosov Ridge[11]. Unit K is a dark yellowish-brown foraminifera-rich, silty lutite that ranges in thickness from 14 to 53 cm, is intensively burrowed and is finer-grained than adjacent units. It has been interpreted as representing an interval of reduced glacial ice influx in the Arctic (that is, the glacial ice minimum).

Sediments on Banks Island provide the best record of Pleistocene events in the western Canadian Arctic Archipelago. Three continental glaciations (Banks, Thomsen and Amundsen) as well as preglacial and intervening interglacial periods (Morgan Bluffs and Cape Collinson) have been documented[12,13] (Fig. 3).

A preliminary palaeomagnetic investigation[5] of the Duck Hawk Bluffs of southwestern Banks Island, where all recognized glacial and nonglacial events are recorded[14], indicates that the preglacial sediments, and the glacial and marine deposits laid down during the oldest and most extensive Banks Glaciation, and during part of the Morgan Bluffs Interglacial, are probably of Matuyama age (>730 kyr) (Fig. 3). Younger terrestrial deposits associated with the Morgan Bluffs and Cape Collinson interglacials, and the glacial and marine deposits associated with the Thomsen and Amundsen glaciations, are normally magnetized and probably of Brunhes age (<730 kyr). The Banks Glaciation is the only one in which continental ice overrode most of Banks Island and probably large areas of other western Arctic Islands, extending some distance in the ocean. During the younger glacial stages the ice filled some of the inter-island channels and impinged on coastal areas but may have not extended very far into the ocean.

Figure 3 is a tentative correlation of the glacial and interglacial deposits of Banks Island with the lithostratigraphical units recognized in the central Arctic Ocean. The Morgan Bluffs Formation includes terrestrial interglacial deposits and unit K represents a time of reduced glacial ice activity in the ocean. The younger Thomsen and Amundsen glaciations, the Cape Collinson Interglaciation, and Holocene deposits from Banks Island correlate with the upper part of unit K, and units L and M, which are glacial–marine units that include alternating coarse- and fine-textured sediment; these represent alternating intensive and less intensive ice rafting.

The older Banks Glaciation glacial and associated marine deposits, represented by the Duck Hawk Bluffs Formation (Fig. 2), record the strongest advance of a continental ice sheet in the western Canadian Arctic Archipelago and are probably correlative with unit J in the oceanic record. Unit J is one of the coarsest grained units of the late Cenozoic stratigraphy and commonly shows a large coarse peak on graphs of texture (Fig. 4). Because the Banks Glaciation is the strongest glacial advance recognized in the western Canadian Arctic, it is reasonable to expect that the ocean record of this event was a very pronounced increase in coarse sediment. In detail, unit J (Fig. 4) commonly has two prominent coarse zones separated by a finer-grained interval. This suggests that if a correlation with the Banks Glaciation is real, the Banks interval may have included more than one surge of ice, a fact which should be recorded on southern Banks Island by the presence of multiple stacked and distinct Banks Glaciation tills[13]. Because terrestrial glacial and interglacial deposits could experience more erosion than their equivalents in the ocean, the marine record should be more complete. It has also been suggested that unit J can be correlated with oxygen isotope glacial stage 22 (ref. 7).

The recognition of the Bruhnes–Matuyama magnetic signature in Pleistocene sediments of Banks Island permits the first correlation of Canadian continental glacial and interglacial deposits with Arctic Ocean sediment. The Morgan Bluffs Formation is interpreted to be an interglacial deposit and its correlative, unit K, is a silty lutite that has been interpreted to have been deposited during time of reduced continental glacial ice activity[3].

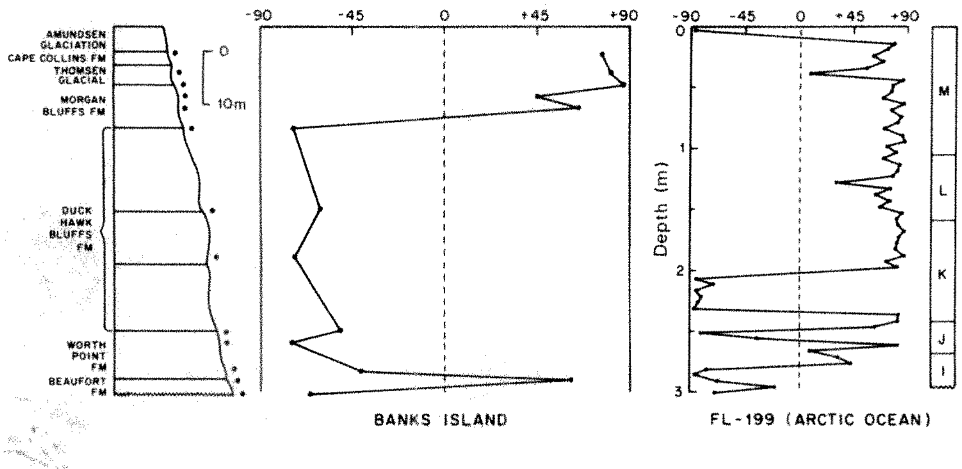

Fig. 2 Magnetic inclination plots for a representative Central Arctic Ocean core compared with a similar plot for Banks Island; the Arctic plot is representative of cores[8,10], and the Banks Island data are based on multiple samples[5]. Note that Banks Glaciation is represented by Duck Hawk Bluffs Formation.

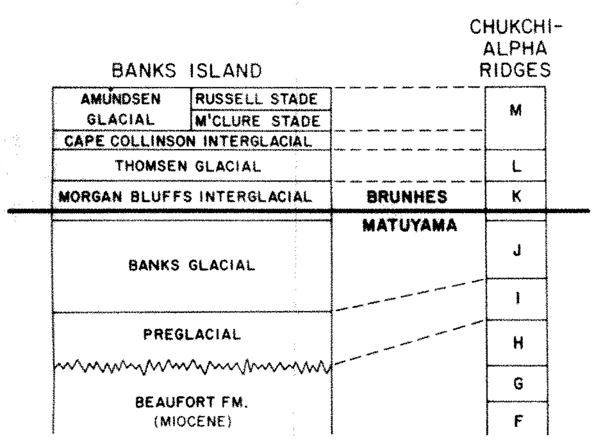

Fig. 3 Correlation of the Banks Island terrestrial deposits[8,9] and glacial–marine stratigraphy of the central Arctic Ocean[7]. The Brunhes normal and Matuyama reversed magnetic intervals in terrestrial and marine sequences are indicated. Marine unit K has previously been interpreted to be of interglacial marine origin[7].

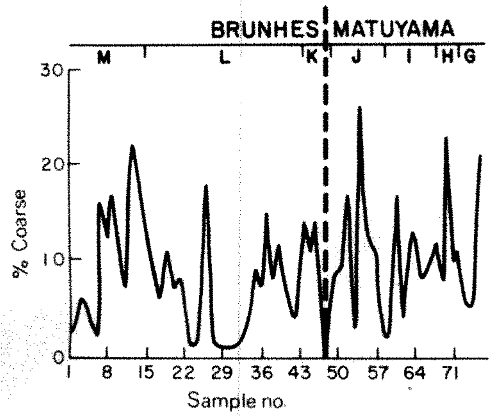

Fig. 4 Per cent coarse sediment (>62 μm) in Arctic Ocean core FI-196, at 80°33′ N, 171°34′ W, from 3,327 m depth. '1', is the core top with samples at 1-cm intervals. The Brunhes–Matuyama magnetic boundary (730 kyr) is indicated as is M, L, K, J, I, H, and G stratigraphy for the core[7]. Coarse peak in J probably correlates with Banks Glacial (Duck Hawk Bluffs Formation, Figs 2, 3).

The other stratigraphical units identified in the Arctic Ocean and differentiated by texture provide a record of glacial and interglacial events that can be correlated with the terrestrial deposits. This apparent confirmation of the significance of oceanic glacial–marine textural relationships with continental glacial and interglacial sediments provides a powerful tool for marine–terrestrial–glacial correlations. This Arctic terrestrial–marine correlation should permit significant palaeoclimatic interpretations that are based on sediment texture.

Patterns of junctional communication in the early amphibian embryo

Sarah C. Guthrie

Department of Anatomy and Embryology,
University College London, Gower Street, London WC1E 6BT, UK

It has long been recognized that cells in early embryos can communicate with each other via a direct cell-to-cell pathway, probably mediated by gap junctions. Low electrical resistance pathways, detected electrophysiologically, have been identified in all species examined so far. However, studies in various embryos on the transfer of molecules larger than small ions (for example, fluorescent dyes in the molecular weight range 350–500) have given conflicting results[1–5]. In all these studies the ability to transfer dyes from cell to cell was determined without reference to the position of the injected cell in the embryo. In the experiments reported here, cell–cell transfer of the fluorescent dye, Lucifer yellow[6] (molecular weight (M_r) 450) was re-examined in the early *Xenopus laevis* embryo by injecting the dye into identified cells, as the position of the injected cell within the embryo may be important. At the 32-cell stage, we found that dye transfer often occurred between animal pole blastomeres which were not sisters, as well as between sister cells, and also that Lucifer yellow was indeed transferred via gap junctions. The cell–cell transfer was not uniform within the animal pole; transfer was maximal near the dorsal side and minimal at the ventral side. This pattern may reflect differences in permeability or numbers of gap junctions across the embryo, and could be related to early events in development.

Previous studies[1–5] investigating the transfer from cell to cell of fluorescent dyes in the molecular weight range 300–500 in various embryos have yielded inconsistent results. Dye transfer has been reported in *Fundulus* embryos[1], mouse embryos[2] and blastomeres from axolotl embryos[1]. Conversely, the absence of cell–cell transfer of such dyes has also been demonstrated in *Fundulus*[3], and in starfish embryo[4] and blastomeres of early *Xenopus* embryos[5]. These studies failed to identify the position of the injected cell within the embryo, and it is now clear that restriction of dye transfer can occur at the site of a developmental boundary, for example, the segmental border in the insect *Oncopeltus*[7]. This has also been suggested by experiments in the mouse embryo[2] and in *Drosophila* imaginal disk[8]. Thus it is possible that transfer between cells of molecules in this molecular weight range depends on the position of the injected cell in the early embryo. This possibility has now been tested in the early *Xenopus* embryo.

All injections were made at the 32-cell stage of development. In preliminary studies, where animal pole cells were injected randomly with respect to position, Lucifer yellow was often found to pass between cells which were not sisters, frequently filling two or more other cells, but not often more than four or five. However, instances of no transfer within the observation period (up to 20 min after injection) were also observed, consistent with previous observations in this embryo[5]. In whole embryos the visual assessment of failure to transfer was sometimes complicated by pigmentation, scatter and autofluorescence. Scatter was largely eliminated by closing down the diaphragm, and scanning across cells appearing to contain dye. Frozen sections were then used to confirm the determination made on the whole embryo (see Fig. 2).

In order to eliminate complications introduced by the persistence of cytoplasmic bridges from the previous cleavage, several injections used fluorescein isothiocyanate (FITC)-conjugated dextrans, whose high molecular weight (10,000) prevents their passage through gap junctions[9]. The results showed that FITC–dextrans were often present in two cells which were daughters of the previous cleavage (that is, sisters at the 32-cell stage) but never in more than these two cells. As Lucifer yellow frequently filled cells that were not sisters, it was assumed to transfer via gap junctions. The timing of the disappearance of

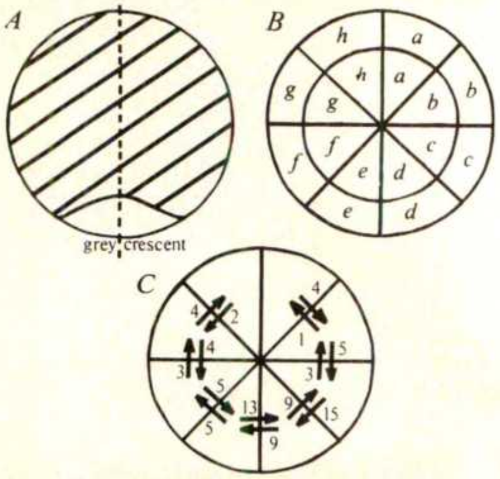

Fig. 1 Map of the *Xenopus* embryo. *A*, The pigmentation pattern of the animal pole of the *Xenopus* egg, at the time when the lifting of the pigment at the grey crescent becomes apparent. The grey crescent is bisected by the primary cleavage axis, and is fated to become the future dorsal side of the embryo, while the opposite side will be ventral. Eggs were obtained by inducing pairs of *Xenopus laevis* to lay by injection of chorionic gonadotropin. *B*, The nomenclature of the cells used in these experiments in a 32-cell embryo, viewed from the animal pole. Embryos at the 32-cell stage, with regular cleavage pattern and identifiable grey crescent were mechanically dejellied and placed in a wax bath filled with half-strength Ringer's solution (60 mM NaCl, 1.25 mM KCl, 4 mM $CaCl_2$, 1 mM Tris, *p*H 7.4) in their normal orientation with the animal pole upwards. Sixteen radical cells were then visible, with pairs of sister cells lying in the same segment, and position identifiable with respect to the grey crescent. *C*, The predominant dye movements in the 32-cell embryo, labelled with the direction and number of instances of transfer. Because of the unknown duration of cytoplasmic bridges between sister cells, dye movements are shown between segments of the animal pole, each consisting of two sisters of the previous cleavage. Note that transfer was bidirectional across all segments except across the primary cleavage axis at the ventral end. The high incidence of transfer across the axis at the dorsal side, from segment *d* to *e* and vice versa, emphasized this asymmetry.

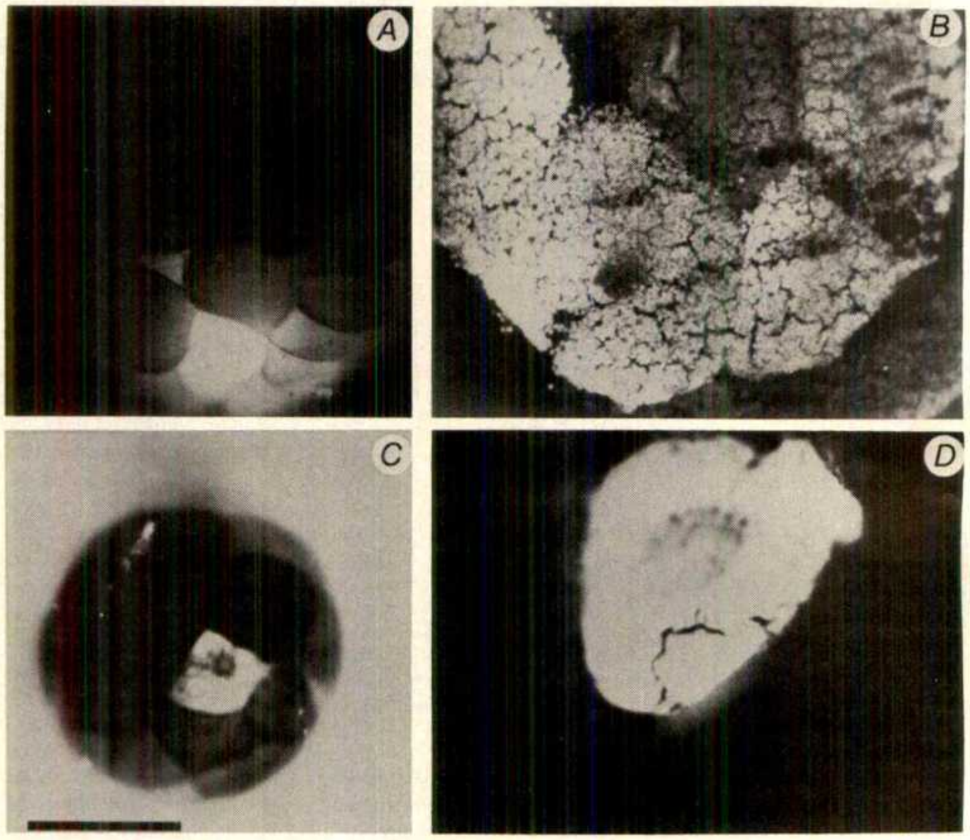

Fig. 2 Photographs of Lucifer yellow-injected embryos. *A*, A whole embryo injected with Lucifer yellow into cell *d* (inner ring) at the 32-cell stage. The embryo has begun to cleave to 64 cells, and there is extensive transfer into several other cells. Scale bar, 500 μm. *B*, A frozen section of an embryo with dye injected into cell *d*. The injected cell is the largest in the field of view with a prominent nucleus, and has transferred dye in the lateral direction to three other cells. Scale bar, 200 μm. *C*, A whole embryo with dye injected into cell *a* (inner ring) at the 32-cell stage with no transfer apparent. Scale bar, 600 μm. *D*, A frozen section of an embryo with dye injected into cell *a*, with sharp restriction of dye to the injected cell. Scale bar, 200 μm.

Methods: For Lucifer yellow injection, microelectrodes were filled with 2% Lucifer yellow, and backfilled with 1% LiCl (resistance 20 MΩ). After impalement and sealing, indicated by a good resting potential (20 mV), rectangular hyperpolarizing pulses (100 nA, 30 ms duration, 10 Hz) were used to iontophorese dye into cells, using a standard injection time of 5 min. To inject 4% FITC–dextran (Sigma) I used a hand syringe or pressure injection unit (Picospritzer II). Immediately after injection, embryos were examined by fluorescence microscopy, and the pattern of dye spread out from the injected cell was noted diagrammatically. The injected cell was often slightly swollen, but this had no deleterious effects, as injected embryos could be grown into normal tadpoles in tap-water. Some embryos were fixed in 4% formaldehyde for frozen sectioning (1 h fixation followed by freezing in isopentane and sectioning at 20 μm on a Bright 5030 microtome) or plastic sectioning (4–5 h fixation followed by dehydration in alcohols, overnight infiltration and embedding in methacrylate resin, then sectioning at 10 μm on a Du Pont Sorvall UB4 microtome).

cytoplasmic bridges varied from embryo to embryo; all cases of transfer of Lucifer yellow into the sister cell only were therefore scored as instances of failure to transfer.

To test whether the non-uniform transfer of dye between cells was related to the position of the cell within the animal pole, injections were made into cells whose position had been reliably identified with respect to the primary cleavage axis and the grey crescent. Figure 1*A* and *B* shows the nomenclature used. Sixteen injections were made into cells at each position, so that 256 embryos were injected in all. Photographs of whole embryos and sections showing examples of presence and absence of transfer are shown in Fig. 2.

The pattern which emerged was that cells near the grey crescent transferred dye in a majority of cases, but those distant from it transferred little dye. The data from all these experiments are given in Fig. 3, as plots of the number of embryos (out of a total of 16) for each identified cell, which showed no transfer, transfer to sister cell only, or transfer to one or more other cells, not including the sister. For the inner ring, cells *c*, *d* and *e*, at the grey crescent side (future dorsal), clearly exhibited the best transfer. By contrast, cells *a* and *h* (at the future ventral side) rarely transferred dye into their lateral neighbours. The pattern of transfer was shifted slightly to the right of the primary cleavage axis at the grey crescent end. A similar pattern was seen for the outer ring of cells, although the total amount of transfer was substantially greater. Table 1 summarizes the data from these experiments, giving the percentage of observed cases of transfer and no transfer for each cell. From this it is clear that even cells which frequently transferred dye, for example cell *c*, could sometimes fail to transfer, just as cells which seldom transferred dye occasionally showed the opposite behaviour. There is no evidence for corresponding differences in electrical coupling across the embryo, though accurate quantitative measurements of the extent of electrical coupling are difficult to obtain. Using

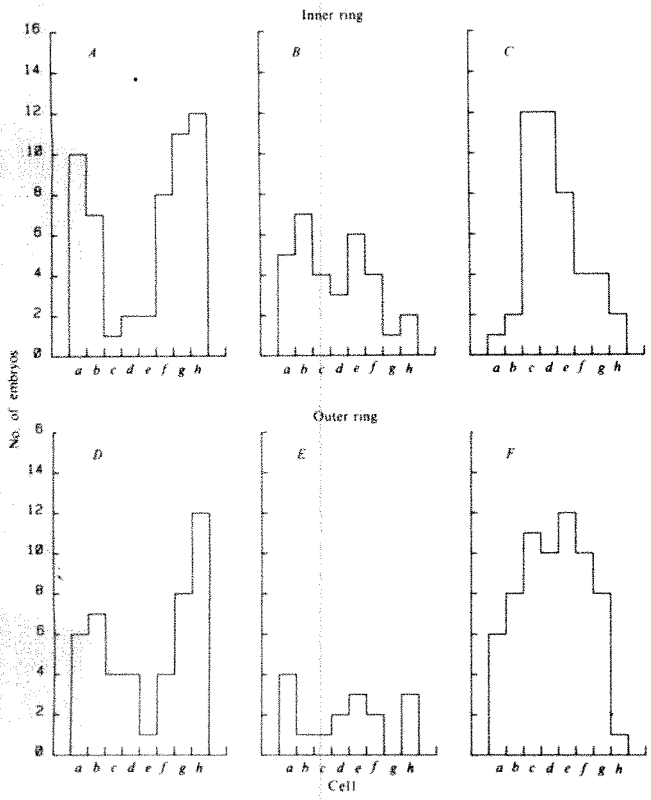

Fig. 3 Graphs showing distribution of Lucifer yellow transfer in the 32-cell embryo. Plots *A* and *D* show the number of instances of no transfer from cells in the inner and outer ring respectively. *B* and *E* show incidence of transfer to sister cell only, and *C* and *F* incidence of transfer to one or more other cells not including the sister cell. The irregularity of graphs *B* and *E* reflects the finding that transfer between sister cells appears to be random with respect to position. Graphs *A* and *D* show that the least transfer occurred at the non-grey crescent side of the embryo, while the predominance of transfer at the grey crescent is evident from graphs *C* and *F*, especially for cells *c* and *d* in the inner ring, and cell *e* in the outer ring.

the χ^2 test, statistical comparison of the observed patterns of transfer on the assumption that there was an equal probability of observing transfer throughout the embryo showed that the chance of these patterns occurring at random is $<1\%$.

Examination of the qualitative nature of the pattern of dye transfer showed preferences in the direction of transfer from individual cells. The major dye movements in the 32-cell embryo are mapped in Fig. 1*C*. As noted above, dye transfer occurred predominantly at the grey crescent side of the embryo, especially between segments *d* and *e*. A striking finding was the presence of bidirectional transfer between all segments except at the ventral side between *a* and *h*, where no instance of transfer was observed.

The data presented here suggest that there were pronounced asymmetries in the degree and direction of spread of dye from cells of the early *Xenopus* embryo. Differences in number or permeability of gap junctions could be responsible for the gradient of transfer from the dorsal to ventral side, though the factors which govern direct cell–cell communication in embryonic systems are as yet unknown. The more interesting question raised by these findings, however, is whether this phenomenon has developmental implications; evidence of stage-dependent changes in the pattern of dye transfer would support this. Further experiments on the early *Xenopus* embryo have shown a progressive restriction of dye transfer from the 16-cell through to the 32- and 64-cell stages, followed by an increase at the early blastula stage. These results will be elaborated elsewhere, together with data from injections using probes of different sizes. Manipulations which disrupt the pattern of cell to cell communication, and produce a parallel disruption in development, would also provide persuasive evidence for a developmental link. One such manipulation is described elsewhere in this issue[10].

Table 1 Dye transfer between identified animal pole cells at the 32-cell stage

Inner ring	Instances of no transfer or transfer to sister cell only % (*n*)	Instances of transfer to one or more other cells, not sister cells % (*n*)
Cell *a*	94 (15)	6 (1)
b	87.5 (14)	12.5 (2)
c	31 (5)	69 (11)
d	31 (5)	69 (11)
e	50 (8)	50 (8)

g	75 (12)	25 (4)
h	87.5 (14)	12.5 (2)
Outer ring		
a	62.5 (10)	37.5 (6)
b	50 (8)	50 (8)
c	31 (5)	69 (11)
d	37.5 (6)	62.5 (10)
e	25 (4)	75 (12)
f	37.5 (6)	62.5 (10)
g	50 (8)	50 (8)
h	94 (15)	6 (1)

The numbers and percentages of transfer and cases of no transfer observed for each cell. Instances of transfer to the sister cell only were regarded as no transfer, as sister cell transfer depended on the time in the cleavage cycle when the injection was made. The observed distribution of transfer from all cells examined was compared with a distribution in which the probability of transfer from all cells was taken to be 50%, by the χ^2 test. The observed distribution was shown to be significantly different $(0.01 > P > 0.005)$. For a comparison between the observed results and a distribution in which the probability of transfer is 100%, $0.005 \gg P$. *n*, Number of embryos.

I thank Anne E. Warner for advice. I am in receipt of an MRC studentship. Lucifer yellow was kindly donated by W. W. Stewart.

Transient expression of a surface antigen on a small subset of neurones during embryonic development

Kathryn J. Kotrla & Corey S. Goodman

Department of Biological Sciences, Stanford University, Stanford, California 94305, USA

During development, neurones find and interconnect with their targets in a remarkably precise way. The unfolding of neuronal specificity involves a series of highly specific recognition events which are likely to be coordinated by the spatial and temporal expression of many different surface molecules. At early stages of development, neuronal recognition occurs most dramatically at the tips of growing axons, at growth cones and their filopodia[1,2]. Previous studies on the grasshopper embryo suggest that specific filopodial contacts lead to the stereotyped patterns of selective

axonal fasciculation; these results support the 'labelled pathways' hypothesis which predicts that the different neighbouring axon fascicles in the embryonic neuropil within filopodial grasp are differentially labelled[3–8]. To uncover the molecular labels on fasciculating embryonic axons, we screened 2,000 monoclonal antibodies generated against the embryonic neuroepithelium[9]. Here we describe three antibodies which reveal surface antigens whose temporal and spatial expression during embryogenesis correlate with the predictions of the model. In particular, the Mes-2 antibody recognizes an antigen which is transiently expressed on the surface of only 4 out of ~1,000 neurones in each metathoracic hemisegment during a short period of embryogenesis. The growth cones of two of these neurones fasciculate in the periphery and innervate the same target. Moreover, they transiently express the Mes-2 surface antigen while doing so.

In the 40% grasshopper embryo, the G growth cone is within filopodial grasp of ~25 different longitudinal axon fascicles (made up of ~100 different axons), and yet invariably fasciculates on the A/P fascicle; when the A/P fascicle is ablated, the G growth cone does not show a high affinity for any other fascicle[5–8]. Furthermore, extensive ultrastructural[7] and experimental[8] analysis demonstrates that G is able to distinguish the two P axons from the two A axons within the A/P fascicle. Given this specificity, it seems reasonable to hypothesize that each of the ~25 longitudinal axon fascicles, and perhaps subsets of axons within the fascicles, are differentially labelled.

To identify molecules whose temporal and spatial expression correlate with this prediction, we generated monoclonal antibodies against the grasshopper embryo central nervous system (CNS)[9]. In three fusions (NS-1 myeloma cells), BALB/c mice were immunized with 40% grasshopper neuroepithelium; in a fourth fusion (from which monoclonal antibody Mes-2 was generated), mice were first immunized with whole *Drosophila* embryos and boosted with 40% grasshopper neuroepithelium. Approximately 2,000 wells were screened on lightly fixed wholemount embryos.

The Mes-3 and Mes-4 monoclonal antibodies stain only one longitudinal axon bundle (that pioneered by the MP1 and dMP2 axons) out of ~25 different fascicles in each hemisegment in the 40% embryo (Fig. 1*d*); the antigens recognized by these antibodies are expressed from the beginning of axonogenesis to the end of embryogenesis. This demonstrates that an individual fascicle is antigenically distinct from all other fascicles within filopodial grasp at the time growth cones are choosing between them. The Mes-3 and Mes-4 antigens (as well as the Mes-2 antigen described below) are also expressed on the surface of the muscle pioneers, large mesodermal cells which provide guidance cues for mononeurone growth cones[10]. The finding that all three antibodies recognize the surfaces of the muscle pioneers is striking, but its significance is unclear.

The Mes-2 antigen is transiently expressed on only 4 out of ~1,000 neurones in each metathoracic (T3) hemisegment (Fig. 1*a*, *b*) during a short period of development (Table 1). The four neurones comprise two interneurones (IN X and IN Y; little is known about their central axon pathways), and the two excitatory motoneurones that innervate the extensor tibiae (ETi) muscle in the leg–FETi (F in Fig. 1*a*, *b*; from neuroblast 4-4) and SETi (S in Fig. 1*b*, *c*; from neuroblast 2-3). Staining of the cells with Mes-2 antibody in either highly dissected living preparations or fixed but unpermeabilized preparations (cytoplasmic antigens require detergent treatment in these whole-mount preparations) indicates that the Mes-2 antigen is on the cell surface.

The growth cones of FETi and SETi follow the same final axonal pathway and innervate the same muscle. Of the ~100 motoneurones in each T3 hemisegment whose growth cones innervate muscles in the body wall or limb bud, only FETi and SETi express the Mes-2 antigen. Although these two motoneurones arise from different neuroblasts, they alone amongst their two families share a final axonal pathway and target, and express Mes-2. Two other neurones also innervate this muscle later in development: they are the CI inhibitory

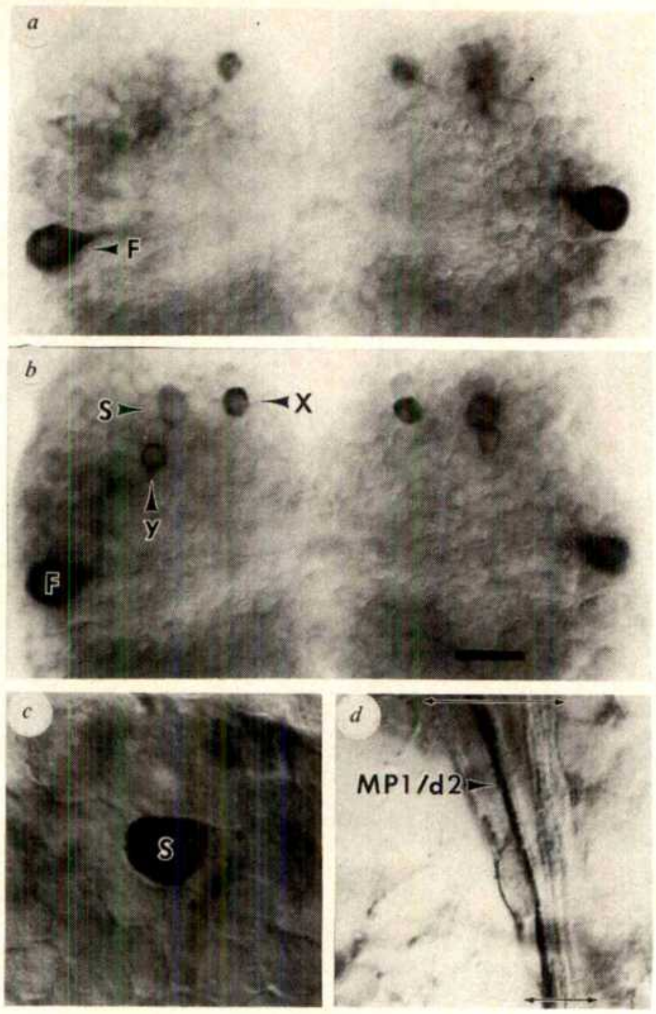

Fig. 1 Binding of Mes-2 (*a*–*c*) and Mes-3 (*d*) monoclonal antibodies to small subsets of neurones in the grasshopper embryo. *a*, *b*, Two different focal planes of a 60% metathoracic (T3) ganglion showing four cell bodies (out of 1,000 on each side) labelled by Mes-2 antibody: F, FETi, fast extensor tibiae motoneurone; S, SETi, slow extensor tibiae motoneurone; X, interneurone X; Y, interneurone Y. The Mes-2 recognizes a surface antigen that is transiently expressed on the axons and cell bodies of these four neurones. *c*, Transient expression of Mes-2 antigen (see Table 1). At 55% of development shown here, SETi expresses the antigen at a high level, whereas by 60% (*b*), SETi's expression is already declining, in contrast to that of FETi and interneurone X. *d*, The MP1/dMP2 fascicle is specifically labelled by the Mes-3 antibody. Only one out of ~20 axon bundles is stained in the longitudinal connective at 38% of development. Lines with arrows shown at the top and bottom of the figure mark the medial (left) and lateral (right) extent of the longitudinal axon fascicles as shown here on the right side of a single segment. Horseradish peroxidase (HRP) immunohistochemistry was performed by fixing embryos in 2% paraformaldehyde for 1/2 h, followed by incubation with antibody supernatant and subsequent protocol for the biotin/avidin HRP system (Vectastain ABC kit, Vector Laboratories). Although the Mes-2 and Mes-3 antibodies bind to surface antigens in living embryos, in all photographs shown here, 0.2% saponin was added for better visualization. Such detergent treatment reveals that the Mes-2 antigen is also within the cytoplasm in the cell bodies of the four neurones. Calibration bar: *a*, *b*, 40 μm; *c*, *d*, 15 μm.

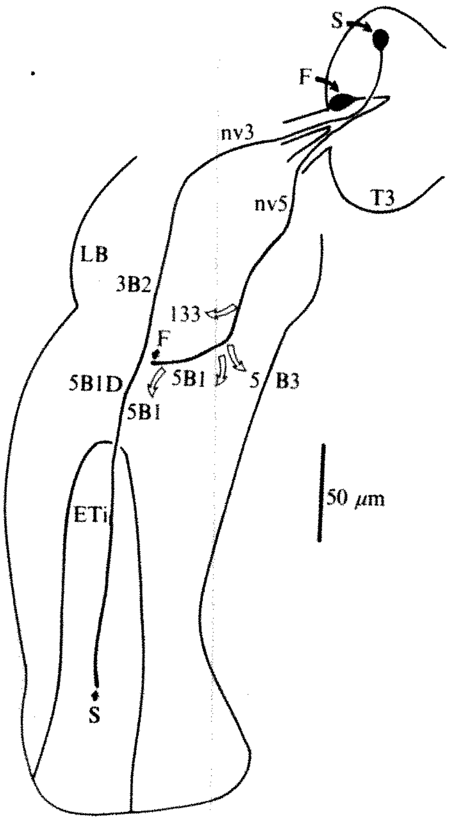

Fig. 2 Camera lucida drawing of the axons of the SETi and FETi motoneurones at 48.5% of development. At this stage, both FETi and SETi have just begun to express the Mes-2 antigen on their surface, as indicated by double labelling experiments using the Mes-2 monoclonal antibody and intracellular dye injections of Lucifer yellow followed by HRP immunocytochemistry with the anti-Lucifer yellow antibody[12]. At this stage, FETi's growth cone is just about to contact SETi's axon in the femur of the limb bud (LB). The cell bodies of both motoneurones are in the T3 ganglion and SETi's growth cone at this stage is already extending across the extensor tibiae (ETi) muscle pioneers[10]. On its way to its target, FETi's growth cone came within 2 µm of SETi's axon as it left the CNS; at that stage, neither cell expressed the Mes-2 antigen. On its way out as nerve 5, FETi's growth cone extended past the muscle pioneer for coxal muscle 133a, where the growth cones of three motoneurones branch off. It then reached a pathway trifurcation in the limb bud, in which it extended along nerve 5B1 instead of nerves 5B3 (followed by flexor motoneurones) or nerve 5B2 (followed by tarsal motoneurones). It then extended off from nerve 5B1 towards SETi's axon in nerve 3B2 (which becomes 5B1D). After the time shown in this figure, FETi fasciculates on SETi's axon and extends distally towards the ETi muscle. For implications, see text. Unfortunately, technical difficulties of antibody access in the 48.5% limb bud prevented us from using antibodies to block function in the living embryo.

motoneurone which also innervates several other muscles, and the DUMETi modulatory neurone which innervates other targets as well.

The Mes-2 antigen is not expressed on either FETi or SETi at the time their growth cones are extending along different central and peripheral axonal pathways. SETi's growth cone pioneers nerve 3 (ref. 11) and extends distally into the femur of the metathoracic limb bud where it extends along the ETi muscle pioneers[10]. At about this time, the FETi growth cone reaches the exit point of the CNS where several axon fascicles diverge as they extend distally as peripheral nerves. Although FETi's growth cone is within short filopodial grasp (2 µm) of SETi's axon, it does not fascilitate with SETi but instead extends out nerve 5 (Fig. 2). At this stage (~40%), neither cell expresses the Mes-2. FETi's growth cone extends out into the limb bud and then makes several other pathway choices.

At 49% of development, FETi's growth cone once again comes into contact with SETi's axon in the femur of the limb bud, and now fasciculates with SETi's axon, following it distally to the ETi muscle pioneers; at this stage of development it is the only axon to do this. Clearly, one or both of the cells has changed since their previous encounter over 24 h earlier.

Double labelling of the neurones with the Mes-2 antibody and intracellular injections of the dye Lucifer yellow reveal that expression of Mes-2 on the processes and cell bodies of both cells begins at 48.5%, just before FETi's growth cone reaches SETi's axon. Their expression of Mes-2 is transient (Table 1; compare S in Fig. 1*c* at 55% and *b* at 60%). After reaching and innervating their common muscle, expression of the Mes-2 antigen decreases dramatically and eventually disappears, and does not reappear during larval and adult life.

The data suggest that the Mes-2 antigen may be involved in the selective fasciculation of FETi's growth cone onto SETi's axon. Only when both cells express the antigen on their surface do they fasciculate. The Mes-2 antibody demonstrates (1) the remarkable specificity of a surface antigen on a very small subset of neurones (4 out of 1,000, 2 of which fasciculate in the periphery) and (2) the transient expression of a surface antigen during the narrow time window of development in which axon outgrowth and cell recognition occurs. It will thus be of interest to isolate the surface molecules recognized by such antibodies as Mes-2, Mes-3 and Mes-4, and to characterize their function during neuronal development.

We thank Lily Jan and Yuh Nung Jan for help in the grasshopper/*Drosophila* fusion from which Mes-2 was isolated, Amy Sater for help in isolating Mes-4,, Pauline Sallata and John Berlot for technical assistance, and John Thomas for criticizing the manuscript. The work was supported by NIH grant and McKnight Scholars Award to C.S.G.

Cell surface molecules have been implicated in cell interactions which underlie formation of the nervous system. The analysis of the functional properties of such molecules has profited from the combined use of antibodies and cell culture systems. It has been suggested that the interplay between these molecules modulates cell-to-cell interaction at critical developmental stages[1,2]. In the mouse, N-CAM[1,3] and L1 antigen[4] have been shown to mediate Ca^{2+}-independent adhesion among neural cells. N-CAM plays a role in fasciculation of neurites and formation of neuromuscular

junction. L1 is apparently not involved in synaptogenesis, but in migration of granule cell neurones in the developing mouse cerebellar cortex[5]. The two antigens are distinct molecular and functional entities which act synergistically in aggregation of neuroblastoma[6] and early postnatal cerebellar cells[7]. In view of a certain similarity in function between the two groups of molecules, it was not surprising to find that structural similarities are detectable by the monoclonal antibody L2. We show here that a carbohydrate moiety recognized by L2 and HNK-1 monoclonal antibodies, is present in mouse N-CAM and L1. The L2 epitope appears on all major neural cell types but not all N-CAM molecules express it. This heterogeneity points to a previously undetected molecular diversity which may have functional implications for modulating cell adhesion during development.

To demonstrate that L2 antibodies react with L1 antigen and mouse N-CAM Western blots were performed with the two antigens which had been immunoaffinity purified on the respective monoclonal antibody columns. In this study, monoclonal antibody BSP-2 was used to purify and test mouse N-CAM[8,9]. L2 and HNK-1[10–12] antibodies recognized the 200 and 140 kilodalton (kd) constituents of L1 and the 180 and 140, but not the 120 kd band of N-CAM isolated from adult mouse brain. In contrast, the 120 kd band of N-CAM was clearly visualized by polyclonal antiserum to BSP-2/N-CAM (Fig. 1). The two antibodies reacted with additional polypeptides present in an Nonidet P40 solubilized crude membrane fraction of adult mouse brain including two bands at 160 and 100 kd and several fainter ones in higher and lower molecular weight regions. The 160 and 100 kd bands were more clearly visualized when L1 and mouse N-CAM were removed from the membrane fraction by sequential immunoaffinity chromatography and the residual polypeptides (designated 'rest L2') recovered by L2 antibody immunoaffinity chromatography (Fig. 1). Polyclonal antiserum to MAG[13] reacted with the 100 kd component, but not with any other polypeptide of 'rest L2' (Fig. 1).

To determine whether the L2/HNK-1 epitopes resided in the carbohydrate or protein moieties, biochemical modifications of the total glycoproteins expressing the L2 epitope were carried out. All L2 positive glycoproteins were obtained from adult mouse brain by affinity chromatography with a monoclonal L2 antibody column and will be designated 'L2 antigen'. The L2/HNK-1 epitopes were found to be heat resistant (95 °C, 15 min) and destroyed by periodate treatment (1 μg antigen in 46 μl 0.07 M Na *m*-periodate, *p*H 5.0, 16 h, 37 °C in the dark, according to ref. 14). Also, when 'L2 antigen' was treated extensively with pronase in denaturating conditions, the carbohydrate containing fraction was isolated by gel filtration and used to compete for L2 and HNK-1 antibody binding to purified 'L2 antigen' in immunospot binding (not shown) and enzyme-linked immunosorbant assay (ELISA) test (Table 1). The results obtained by both techniques and with both antibodies were similar. (It will be shown later by immunocytological methods that the two antibodies compete with each other for binding.) While similar amounts of 'L2 antigen' competed for both antibodies, inhibition by carbohydrate fraction was less efficient and 60 times less for HNK-1 (IgM) than for L2 (IgG) antibodies. Controls for the reaction consisted of carbohydrate fraction obtained in identical conditions from fetuin and used for competition in L2 antibody binding. Furthermore, the carbohydrate fraction from 'L2 antigen' was used for competition in an unrelated antibody-antigen reaction (human haemoglobin). No inhibition of antibody binding was observed in these controls. In an alternate experiment, purified 'L2 antigen' was treated with endoglycosidase F in denaturating conditions[15]. The digested product was then spotted onto nitrocellulose filters which do not permit the adsorption of free carbohydrate chains. L2 and HNK-1 antibodies did not react, while polyclonal L2 antibodies prepared in rabbits against 'L2 antigen' showed maximal binding.

To determine which cell types express the L2 epitope, immunocytochemical studies were carried out on cultured cells using double immunolabelling techniques with established cell

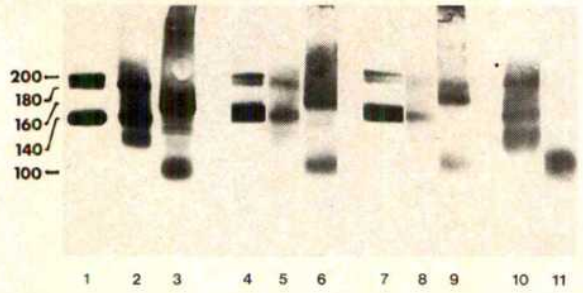

Fig. 1 Western blot analysis of immunoaffinity purified antigens L1, mouse N-CAM/BSP-2 and 'rest L2' from adult mouse brain using monoclonal antibodies L2 and HNK-1 and polyclonal antisera to BSP-2/N-CAM and MAG. Antibodies were described previously[2,3,4,10,13]. L2 antibodies were obtained from two hybridoma clones resulting from an immunization and fusion as described for L1[4]. Another L2 antibody was obtained from a hybridoma clone resulting from an immunization with a glycoprotein enriched membrane fraction from adult mouse brain which showed neutralizing activity towards Fab fragments from antibodies to crude membranes from adult mouse cerebellum in reaggregation of dispase-treated[7] postnatal cerebellar cells. Preparation of crude membrane fraction, immunoaffinity purification of antigens on monoclonal antibody columns and Western blot techniques have been described[4,7]. Immunopurified antigens (visualized by reduced silver staining[4]): lane 1, L1; 2, N-CAM; 3, 'rest L2'. Antigens for Western blots (lanes 4–11): 4 and 7, L1; 5, 8 and 10, N-CAM; 6, 9 and 11, 'rest L2' obtained by sequential immunoaffinity removal of L1 and N-CAM before immunoaffinity chromatography on an L2 antibody column. Antibodies: 4–6, L2 antibody; 7–9, HNK-1 antibody; 10, polyclonal anti-BSP-2/N-CAM antiserum; 11, polyclonal anti-MAG antiserum.

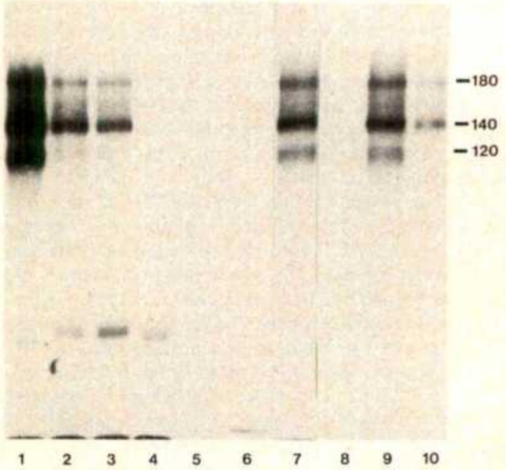

Fig. 2 Sequential immunoprecipitation of immunopurified, iodinated mouse N-CAM with two monoclonal antibodies to N-CAM (H28.123 and P61 (ref. 33) 1, 2, respectively), L2 antibody (3) and L1 antibody (4). Antibody P61 does not recognize the 120 kd band[33]; 5, precipitation with H28.123 after preclearing with H28.123; 6, anti-L2 after preclearing with H28.123; 7, H28.123 after preclearing with anti-L2; 8, anti-L2 after preclearing with anti-L2; 9, H28.123 after preclearing with anti-L1; 10, anti-L2 after precleaning with anti-L1. N-CAM was immunopurified from adult mouse brain membrane in presence of 2-deoxy-2,3-dehydro-*N*-acetyl neuraminic acid (Boehringer, Mannheim) to prevent possible degradation of terminal sugars. Since endogenous endoglycosidase activities in eucaryotic cells are negligible, it is unlikely that the N-CAM preparation contains degraded carbohydrate chains. Immunoprecipitation was carried out with mouse anti-rat kappa mouse Ig coupled to Sepharose as described[7]. N-CAM (5×10^5 c.p.m.) was incubated for 1 h at 0 °C with first antibodies and for 4 h at 4 °C with Sepharose beads. After four washings, supernatants from the precipitates were again treated identically with antibodies and Sepharose beads. Treatment of supernatants with Separose beads was repeated to remove potentially present soluble complexes.

Table 1 Inhibitory capacity of carbohydrate moiety of 'L2 antigen' for binding of L2 and HNK-1 antibodies to immunopurified 'L2 antigen'

Antibodies	Competing compounds			
	'L2 antigen'		Carbohydrate fraction of 'L2 antigen'	
	Half-maximal inhibition	Maximal inhibition	Half-maximal inhibition	Maximal inhibition
L2	0.176 μg	1.76 μg	0.28 μg	1.4 μg
HNK-1	0.176 μg	1.76 μg	16.8 μg	ND

An ELISA test[29] was performed with L2 and HNK-1 antibodies on immunoaffinity purified 'L2 antigen' (20 ng per spot on nitrocellulose filters) in the presence of competing 'L2 antigen' and carbohydrate fraction obtained from 'L2 antigen' by proteolytic digest. Treatment of 'L2 antigen' (2 mg ml^{-1}) in 50 mM Tris, *p*H 8.2 containing 0.1% SDS and 4 mM $CaCl_2$ with pronase (three consecutive additions of 30 μg ml^{-1}, 30 h, 37 °C), subsequent redigestion with pronase (27 h, 37 °C, 2 mM $CaCl_2$) or proteinase K (27 h, 37 °C, 10 mM EDTA), isolation by gel filtration on Biogel P4 and chromatographic analysis of carbohydrate fraction were carried out as described elsewhere[14,30]. Antibodies were used at a concentration of 2 serial dilutions before titre endpoint, 1:200,000 from a 14 mg ml^{-1} stock for L2 and 1:100,000 for HNK-1 and incubated with 'L2 antigen' or carbohydrate fraction (1 h, room temperature) before the ELISA test. Amounts of competing compounds are given in μg protein for 'L2 antigen'[31] and μg carbohydrate for carbohydrate fraction[32] which give half maximal and maximal inhibition of antibody binding. ND, not determined.

type-specific neural markers. In monolayer cultures of early postnatal cerebellar cells the L2 and HNK-1 antibodies reacted with a fraction of tetanus toxin[16], N-CAM and L1 positive neurones, glial fibrillary acidic protein (GFA) and vimentin-positive astrocytes[17] and 04 and 01 antigen-positive oligodendrocytes[18–20], but not with fibronectin-positive fibroblast-like cells[21]. The two antibodies were able to block each other in binding. With time in culture the percentage of N-CAM positive neurones that were also L2/HNK-1 positive decreased from 49±8% or 52±2% after 1 day to 18±5% or 13±3% after 7 days in culture for L2 or HNK-1, respectively.

To investigate the paradoxical finding that only some neurones that are recognized by polyclonal and monoclonal N-CAM antibodies express the L2 epitope, sequential immunoprecipitation of iodinated N-CAM immunopurified from adult mouse brain (see Fig. 1) was performed with antibodies to N-CAM and L2 (Fig. 2). Antibodies to N-CAM removed all further reactivity for the same or for L2 antibody. In contrast, two clearings with anti-L2 removed all material reacting with the same antibody, but left considerable amounts of the 180, 140 and 120 kd bands in solution which could be precipitated by N-CAM antibodies. L2 antibodies removed only 15–20% of the N-CAM that is precipitable by N-CAM antibodies. Similar results were obtained, when the embryonic form of N-CAM was used for immunoprecipitation (not shown). These results support the conclusion that not all N-CAM molecules of both the adult and embryonic forms express the L2 epitope. Furthermore, the L2 antibody did not bind the 120 kd band (Fig. 2).

Since two bands of N-CAM are heterogeneous with respect to expression of the L2 epitope, the most likely explanation for the absence of L2 on N-CAM bearing neurones is a heterogeneity among N-CAM molecules which is distinct from the molecular heterogeneity represented by the adult and embryonic forms. On the other hand, some neurones may express only the 120 kd component. A similar heterogeneity may also exist for L1, since in this case also not all L1 positive neurones were found to express the L2 epitope.

The present study has shown that two cell adhesion molecules share a common carbohydrate moiety also present on myelin-associated glycoprotein. From our experiments we cannot determine whether the two antibodies recognize the same epitope or two distinct epitopes closely associated with each other on the carbohydrate chains so that the antibodies compete with each other for binding. In any case, the L2/HNK-1 epitopes are simultaneously expressed on the same select group of molecules. It has been suggested that myelin associated glycoprotein mediates the interaction of the periaxonal membrane of myelin with the axon[22]. It is possible, therefore, that the common moiety is not only a sign of fortuitous structural homologies between neural cell surface constituents, but implicates that the L2 expressing molecules perform similar functional tasks.

The role of the L2/HNK-1 carbohydrate moiety in cell interactions remains at present unknown. Variations in carbohydrate composition of the embryonic and adult forms of N-CAM underlie differences in adhesive properties[23,24] and it is conceivable that the L2 epitope represents an additional possibility to modulate cell interactions among neural cells. Heterogeneity in expression of the L2 epitope in the population of N-CAM molecules on individual neurones would provide particular cells with the capability to superimpose other tuning modes of adhesion between cell surface receptors and their ligands as they have been described in non-neural systems (see, for instance, ref. 25). Whether adhesive properties are affected in human gammopathies with demyelinating neuropathy and antibodies to myelin associated glycoprotein[26–28] remains an open question.

We thank Andrea Kalkhoff, Magdalena Schlotter and Sabine Ullrich for technical assistance, F. G. Rathjen for producing L2 monoclonal antibodies, R. C. McGarry and J. C. Roder for HNK-1 hybridoma clone, N. Sternberger for MAG antiserum, and Deutsche Forschungsgemeinschaft and Centre National de la Recherche Scientifique for support.

Neuronal-type Na$^+$ and K$^+$ channels in rabbit cultured Schwann cells

S. Y. Chiu*, P. Schrager† & J. M. Ritchie*

* Department of Pharmacology, Yale University School of Medicine, 333 Cedar Street, New Haven, Connecticut 06510, USA

Nerve axons in the central and peripheral nervous system are normally surrounded by satellite cells. These cells, known as Schwann cells in the peripheral nervous system, interact with axons to form a myelin sheath, so allowing nerve impulses to proceed at high speed. Schwann cells are thought to differ from neurones in their membrane properties in one important aspect: they lack excitability. Using the patch-clamp technique we have now measured directly the ionic currents across the membrane of single Schwann cells cultured from newborn rabbits. Surprisingly, we found that these Schwann cells possess voltage-gated sodium and potassium channels that are similar to those present in neuronal membranes.

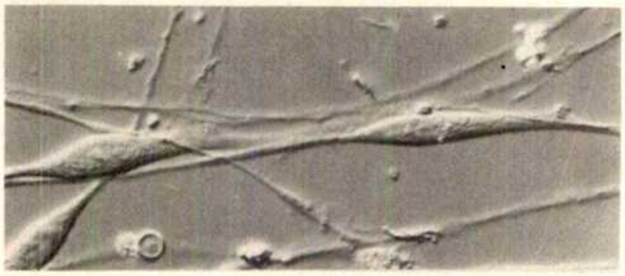

Fig. 1 Two-day-old cultured rabbit Schwann cells under Nomarski optics. (×610).

Figure 1 shows 2-day-old Schwann cells cultured from the sciatic nerves of newborn rabbits[1]. Although markers (such as RAN-1) exist for rat Schwann cells, no such marker is readily available for the rabbit. Schwann cells in the present study were therefore identified morphologically by their characteristic bipolar spindle shape; this is distinct from the flat multipolar appearance of the contaminating fibroblasts that form the only other cellular component of the primary cultures used (and which were not studied electrophysiologically in the present experiments). Although Schwann cells in culture may come to resemble fibroblasts in shape in certain conditions[2], fibroblasts are unlikely to be mistaken for Schwann cells. Proliferation of fibroblasts was inhibited in some cultures by adding cytosine arabinoside to the medium.

Ionic currents were recorded using the patch-clamp technique of Hamill *et al.*[3] in the whole cell configuration. Following formation of a gigohm seal to the cell surface, the patch membrane was broken by excess suction, allowing access to the cell interior. Patch pipettes were filled with solutions in which the primary salt was KCl, CsCl or CsF, together with Ca^{2+} buffered to low concentrations by EGTA. In this system, ion concentrations inside the cell equilibrate with those in the pipette with a time constant of about 5 s (ref. 4). Over 60 cells were studied in cultures for 2–10 days.

Figure 2*a* shows ionic currents recorded from a rabbit Schwann cell with KCl in the patch pipette. The cell was held at −75 mV and test pulses, each preceded by a prepulse to −115 mV, were applied in 10-mV increments, the final potential ranging from −75 mV to +25 mV. The records consist of two components, an early inward current and a delayed outward current. They thus resemble responses found in a number of neurones. We have used pharmacological compounds of known specificities to characterize these Schwann cell currents further. Figure 2*b* shows the effect of the K$^+$ channel blocker 4-aminopyridine (4-AP)[5,6]. Two minutes after adding 6 mM 4-AP to the solution bathing the cell, the delayed outward current was selectively blocked. In other experiments in which the pipette was filled with CsCl, another blocker of K$^+$ channels, only inward currents were observed. We thus conclude that the delayed outward current is a K$^+$ current similar to that found in squid and frog nerves.

The nature of the initial inward current was studied with tetrodotoxin (TTX), a highly selective blocker of Na$^+$ channels[7]. Figure 3 shows inward currents before (*a*) and 30 s after (*b*) the introduction of 60 nM TTX into the bathing solution. Potassium currents in this cell had been eliminated by using a pipette containing CsF. It can be seen that the transient inward current was virtually abolished by TTX. Figure 3*c* illustrates a family of ionic currents which includes depolarizations sufficiently strong to elicit outward transient currents. The pipette solution contained primarily CsCl to block current through K$^+$ channels but included 29 mM Na$^+$. We consistently found that the apparent reversal potential was about +70 mV, which is about 30 mV more positive than the Na$^+$ equilibrium potential. There are at least two possible explanations for this discrepancy. First, most of the steady-state current in Fig. 3*c* was not blocked by TTX or Cs and may thus be flowing through a third ionic channel. This suggestion is supported by the recent findings of anionic[1] and non-selective cationic[8] channels in rat Schwann cells; and we have found single channels in rabbit cells which appear similar to these but will require further characterization. This current would have little effect on our estimate of maximum peak inward current, but might be significant at +70 mV. A second possibility is that the spindle shape of these cells may lead to spatial non-uniformity and poor control of the internal potential by the voltage-clamp.

Although all cells exhibited Na$^+$ currents, the amplitude of the currents varied considerably among different cells (compare Figs 2*a* and 3*a*). For example, the maximum peak inward Na$^+$ current ranged from 50 to 2,100 pA, with an average value of 498 ± 84 pA (±s.e.m., $n = 28$). This variation did not seem to be

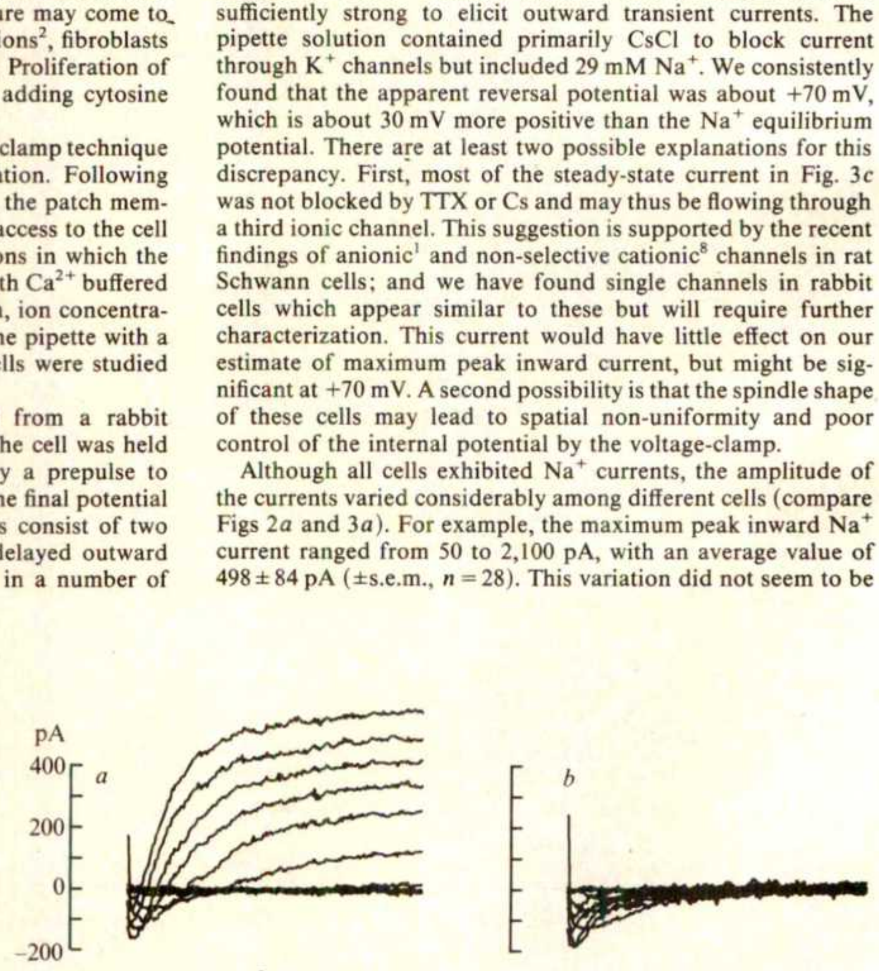

Fig. 2 Ionic currents in 8-day-old cultured rabbit Schwann cells in normal Locke's solution. Records were made using the whole cell configuration of the patch-clamp technique before (*a*) and after (*b*) adding 6 mM 4-aminopyridine externally. The patch pipette was filled with (mM): KCl, 140; CaCl$_2$, 1; MgCl$_2$, 2; EGTA, 11; HEPES, 10; NaOH, 29 to *p*H 7.2. The Locke's solution contained (mM): NaCl, 154; KCl, 5.6; CaCl$_2$, 2.4; MOPS, 10; *p*H 7.4. Test depolarizations were applied in 10-mV steps from −75 mV to +25 mV. The cell was held at −75 mV and 300-ms prepulses to −115 mV preceded each test step. Linear contributions to leak and capacitative currents were removed by scaling and adding the average of several traces elicited by a hyperpolarization to −120 mV. Currents were sampled and digitized at 50-μs intervals. Temperature, 23 °C.

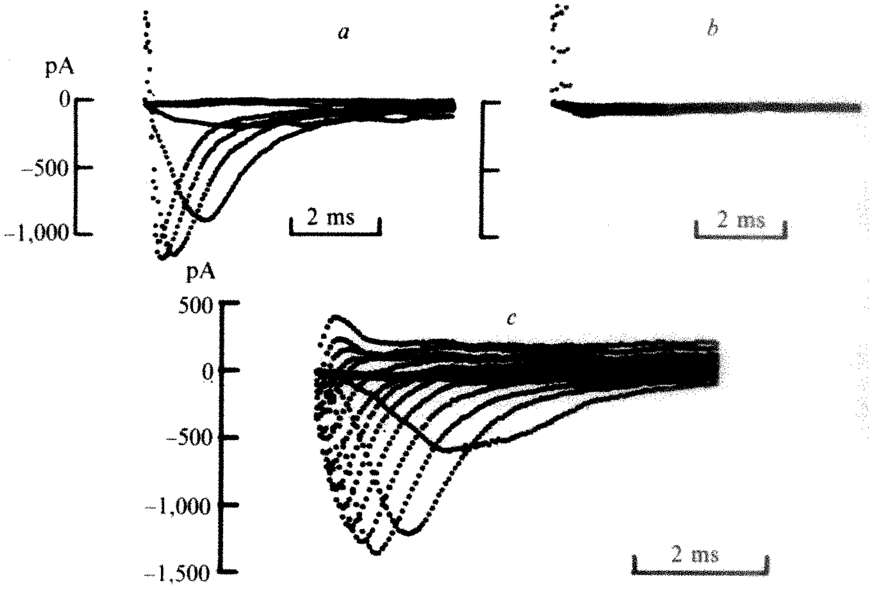

Fig. 3 Ionic currents in 7-day-old cultured rabbit Schwann cells in normal Locke's solution obtained before (*a*) and after (*b*) addition of 60 nM TTX externally. The patch pipette was filled with (mM): CsF, 140; $CaCl_2$, 1; $MgCl_2$, 2; EGTA, 11; HEPES, 10; NaOH, 29 to *p*H 7.2. Holding potential, −74 mV. Prepulses to −114 mV were applied for 300 ms. Test depolarizations were made in 10-mV steps to final potentials ranging from −64 mV to −4 mV. *c*, A family of ionic currents recorded from another (3-day-old) Schwann cell. The feedback resistor in the patch-clamp headstage was reduced to 1 GΩ to allow strong test pulse depolarizations. The pipette solution was identical to that of *a*, *b* except that CsCl was used in place of CsF. The cell was held at −75 mV. Test pulses were applied in 10-mV steps from −55 to +105 mV and were preceded by 300-ms hyperpolarizations to −115 mV. The external medium was normal rabbit Locke's solution.

correlated with the age of the culture. Other factors, such as cell shape or phase of the mitotic cycle, were not examined. The cell capacitance was measured in several experiments by integrating the change in the capacity transient on rupture of the patch membrane. The average value was 20 ± 2 pF ($n = 14$) and the corresponding peak current 30 ± 9 pA pF^{-1} ($n = 14$). Examination of a typical Schwann cell under light microscopy showed the cell to be spindle shaped, about 50 μm from pole to pole, and about 10 μm in diameter in the middle. If any contribution from the small processes at either end are ignored, an upper limit of about 3 μF cm^{-2} is obtained for the membrane capacity of the Schwann cell.

Ritchie and Rang[9] have recently measured the uptake of tritiated saxitoxin (STX) by rat and rabbit sciatic nerves that had undergone axonal degeneration resulting from excision of a small segment of the trunk. In peripheral nerves of rabbit, but not rat, the saturable binding of STX (which blocks Na^+ channels in a manner similar to that of TTX) increases dramatically from about 5 days after sectioning, a time coincident with the known proliferation of Schwann cells in regions distal to the excision. The results presented here thus provide strong support for the idea that these STX binding sites are indeed voltage-sensitive Na^+ channels of the kind generally believed to be restricted to excitable tissue. Glial cells (and fibroblasts) are already known to possess channels that are opened by veratridine and blocked by TTX[10,11]. However, in such experiments there is no evidence of voltage sensitivity; and, in fact, glial cells in particular have long been thought to be inexcitable. Intracellular recording from satellite cells in the leech central nervous system[12] and the squid giant axon[13] has failed to detect any regenerative response. Furthermore, *Necturus* central glia lack a specific, saturable component of binding of STX[14]. By contrast, rabbit Schwann cells do seem to possess the machinery necessary for action potential generation. However, their resting potential, which we have measured to be about −30 to −40 mV, probably inactivates most Na^+ channels, rendering these cells effectively inexcitable. Whether these Na^+ and K^+ channels are included in the myelin lamellae generated by Schwann cells, whether they have any role in remyelination or axonal regeneration, or whether they are conceivably a source of axolemmal Na^+ (and K^+) channels, pose interesting questions for future investigation.

We thank Drs Richard Aldrich and David Corey for invaluable help with patch-clamp techniques, and Ms Bhagya Subramanian for technical assistance in cell culturing. This work has been supported by USPHS grants NS08304, NS12327 and NS17965 and by grant RG 1162 from the US National Multiple Sclerosis Society.

A central question concerning vision is the identity of the biochemical pathway that underlies phototransduction. The large size of the ventral photoreceptors of *Limulus polyphemus* renders them a favourite preparation for investigating this problem[1]. The fact that a single photon opens approximately 1,000 ionic channels in these photoreceptors[2,3] suggests the need for an internal transmitter. We have investigated whether inositol 1,4,5-trisphosphate ($InsP_3$) functions as such an internal transmitter, given that $InsP_3$ may act as an intracellular messenger in other cellular processes[4,5]. Here we report that in *Limulus*, intracellular pressure injection of $InsP_3$ both excites and adapts ventral photoreceptors in a manner similar to light.

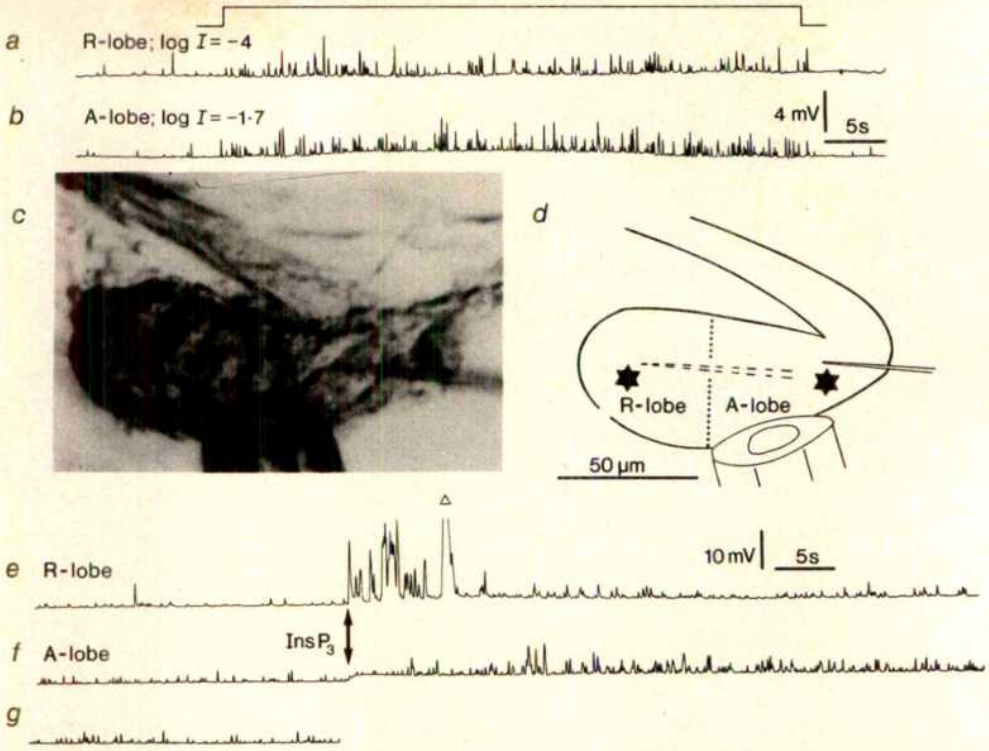

Fig. 1 $InsP_3$-induced excitation of *Limulus* ventral photoreceptor. The photomicrograph (*c*) shows the receptor after the connective tissue had been stripped away[11]. The tip of the suction pipette, which was used for stripping and holding the cell, can be seen in the micrograph. Recordings and injections were made through a pipette, filled with a stock solution containing (in mM): 100 K aspartate, 10 HEPES, *p*H 7.0 in which 20 μM $InsP_3$ was dissolved. Injections of stock solution alone were found to have no effect (30 cells). The cell was first impaled in the A-lobe and the extent of the A-lobe and R-lobe determined by scanning the cell with a 10-μm spot of light[9]. Records *a* and *b* show the response of the R-lobe and A-lobe respectively to steady illumination (square pulse at the top of the traces) with a spot of the indicated $\log_{10}$ attenuation from the maximum available intensity. The R-lobe was found to be approximately 200 times more sensitive to light than the A-lobe[11]. Record *f* shows the response to an $InsP_3$ injection (15 p.s.i., 200-ms pulse at the arrow) into the A-lobe and record *g* shows the recovery 150 s after the injection. Following this injection, the same electrode was inserted into the R-lobe. Sensitivity in the R-lobe was then checked and found to be unchanged relative to *a*. Record *e* shows the response to an $InsP_3$ injection (15 p.s.i., 200-ms pulse at the arrow) into the R-lobe. (The open triangles in the records of this figure and the solid ones in subsequent figures indicate when the recordings went off the scale of the chart recorder.) The sketch of the cell in *d* shows the location of the pipette during injections into the R-lobe and A-lobe. ★ Indicates the location of the spot of light, when centred on the A- and R-lobes. The dotted line indicates the probable demarcation of the R-lobe and A-lobe, as determined by a large change in sensitivity to a spot of light. After record *e* was obtained, the electrode was withdrawn and the A-lobe re-impaled. Results similar to *f* were again obtained (not shown). Similar results were obtained in nine other cells. $InsP_3$, $Ins(1,4)P_2$ and $Ins(4,5)P_2$ were prepared essentially by the method of Grado and Ballou[21] as adapted by R.F.I., M.J.B. and K. D. Brown (in preparation). Briefly, a crude inositide fraction from ox brain was hydrolysed by 1M NaOH and, after neutralization with formic acid, the hydrolysate was fractionated into crude $InsP_1$, $InsP_2$ and $InsP_3$ on Dowex–formate columns[22]. $InsP_3$, $Ins(1,4)P_2$ and $Ins(4,5)P_2$ were further purified by paper chromotography[21] and their identities and purities checked by ionophoresis. A blank region from a paper chromatograph was also eluted and, like the inositol phosphates, de-cationized, followed by neutralization with KOH.

We have previously described the methods for intracellular recording, stimulating and reliably pressure-injecting aliquots of solution of the order of 10 pl (refs 6–9). Injected solutions are specified by the concentration in the pipette. $InsP_3$, inositol 1,4-bisphosphate ($Ins(1,4)P_2$) and inositol 4,5-bisphosphate ($Ins(4,5)P_2$) were prepared as described in Fig. 1 legend; *myo*-inositol, potassium phosphate, *myo*-inositol 2-monophosphate and phytic acid (inositol hexaphosphoric acid) were from Sigma.

The ventral photoreceptors of *Limulus* are segmented into two lobes, a rhabdomeral lobe (R-lobe), specialized for phototransduction, and an arhabdomeral lobe (A-lobe)[10,11], the R-lobe being approximately 100 times more sensitive to light than the A-lobe (Fig. 1*a*, *b*)[11]. When injected into the R-lobe, 20 μM $InsP_3$ reversibly induced, with no detectable latency, the production of discrete waves of depolarization and bursts of waves (Fig. 1*e*). The individual $InsP_3$-induced waves have a similar waveform to the 'quantum bumps' that are evoked by single photons (Fig. 1*a*). Injection of $InsP_3$ into the A-lobe resulted in a response that was both greatly delayed and much smaller (Fig. 1*f*, *g*), as would be expected if the injected $InsP_3$ had to diffuse into the R-lobe in order to produce an effect. The greater sensitivity to $InsP_3$ of the R-lobe, coupled with a similar effect to that of light, suggests that $InsP_3$ acts on the structures of the R-lobe that are specialized for phototransduction.

When measured under voltage clamp, the response to $InsP_3$ (Fig. 2*a*, *c*) is an inward current, as is the light response (Fig. 2*b*). When cells were stimulated with a dim flash (Fig. 2*d*, arrow) followed by an injection of $InsP_3$ (Fig. 2*d*, solid bar), the currents due to light and $InsP_3$ both reversed at approximately +18 mV; this result would be expected if light and $InsP_3$ opened the same ionic channels. Light-adaptation by a bright flash desensitizes the photoreceptor and decreases the $InsP_3$-induced current (Fig. 2*a*–*c*); thus, the response to $InsP_3$ can be light-adapted.

The specificity of the excitatory effect of $InsP_3$ was checked by injecting related compounds. The following had no effect: *myo*-inositol (1 mM, 11 cells), phosphate (1 mM, 10 cells), *myo*-inositol-2-monophosphate (1 mM, 9 cells), phytic acid (1 mM, 6 cells) and a blank from the paper chromatograph (10 cells) (see Fig. 1 legend). $Ins(1,4)P_2$, the degradation product of $InsP_3$, had no effect at concentrations of 20 μM (14 cells) and 100 μM (12 cells); however, two out of three cells exhibited an excitatory effect when 500 μM $Ins(1,4)P_2$ was injected. $Ins(4,5)P_2$ had an excitatory effect at 20 μM (9 cells), indicating that the site of $InsP_3$ action is not selective for $InsP_3$ over $Ins(4,5)P_2$.

As $InsP_3$ excites the receptor, it might initiate other processes that follow excitation, such as adaptation. Figure 3*a* shows localized adaptation by light, in which a prolonged stimulus at position 1 reduced subsequent responses at this position more than at position 2. Similarly, injecting $InsP_3$ at position 1 reduced subsequent responses to light flashes at this position more than at position 2 (Fig. 3*c*, *d*). Desensitization following $InsP_3$ injection under voltage clamp is shown in Fig. 3*e*. We have also observed desensitization of responses to $InsP_3$ following injection of $InsP_3$ (not shown). We have not seen in any cell an $InsP_3$-induced desensitization that was not preceeded by excitation resulting from $InsP_3$ injections. The similarity of the desensitizing effect of $InsP_3$ to that of light suggests that $InsP_3$, or a related compound, initiates processes leading to adaptation as well as to excitation.

A rise in intracellular calcium has been implicated in the adaptation of ventral photoreceptors[12]. The desensitizing effect of $InsP_3$ injection shown in Fig. 3*c*–*e* might be caused by calcium

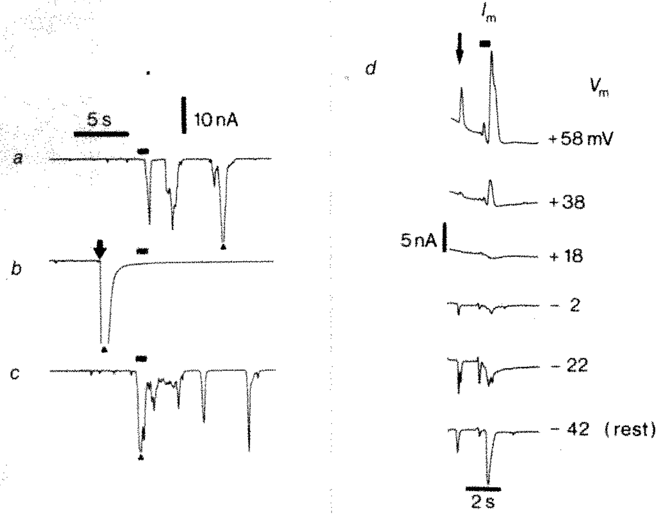

Fig. 2 Light adaptation and reversal potential of $InsP_3$-induced currents. The currents in *a*, *b*, and *c* were obtained from a cell voltage-clamped to its membrane potential (−50 mV) in the dark. The bar above the records indicates the duration of injection with 20 μM $InsP_3$. The arrow above the records indicates a 20-ms flash of uniform white light attenuated by 1.5 log units in *b* and by 5.0 log units in *d*. In *b*, light adaptation blocks the $InsP_3$ response. Spontaneous quantum bumps are present in record *b* before the flash, but not after, indicating that the cell was adapted by the flash. The record in *c* was obtained after the cell recovered sensitivity, following the adapting flash in *b*. A video recording of the injection made under IR illumination[8] allows us to determine that a successful injection occurred in *b* even though there was no effect of the injection. Record *d*, taken from a different cell, shows that the reversal potential of the $InsP_3$-induced current coincides with that of the light-induced current. These voltage-clamp recordings were made in artificial seawater in which the Ca^{2+} was reduced from 10 mM to 1 mM to avoid desensitization produced by voltage-dependent Ca^{2+} entry[23]. The membrane potential (V_m) was moved in 20-mV steps through the reversal potential by a series of 15 s-long command pulses, each beginning 10 s before the test flash. The large steady-state component of the transmembrane current resulting from the voltage step was subtracted from the current records.

contamination of the injection solution; de-cationization of the $InsP_3$ preparation (see Fig. 1 legend) minimized such contamination. Also, six cells were injected with 100 μM $InsP_3$ to which 500 μM EGTA had been added to reduce the free Ca^{2+} to $<10^{-7}$ M; this solution produced the same effects as in Fig. 3 *c–e*. Therefore, it is unlikely that the observed desensitization is due to calcium contamination of the injection solution.

Illumination can facilitate or enhance a photoreceptor's response to a flash of light[7,13–15]. Figure 3*d* shows that the light response at spot 2 was transiently facilitated immediately after $InsP_3$ injection. At a site (spot 1) closer to the injection, this facilitation may be masked by adaptation (Fig. 3*c*). The voltage-clamp recording in Fig. 3*f* was obtained from another cell to demonstrate that the $InsP_3$-induced facilitation could be experimentally separated from $InsP_3$-induced desensitization. Multiple injections of $InsP_3$ produced an approximately threefold facilitation of the light response. Comparison of Fig. 3*e* and *f* illustrates our notion that a sustained facilitation of the light response is associated with a weaker excitation than accompanies desensitization. $InsP_3$ or a related compound may, therefore, initiate facilitation as well as excitation and adaptation.

It is unlikely that $InsP_3$ is the sole messenger in the pathway of adaptation and excitation. Light is thought to release calcium from internal stores so as to adapt the light response in ventral photoreceptors[12,16]. It has been suggested that $InsP_3$ causes the release of calcium from an intracellular compartment in pancreatic acinar cells[5] and in hepatocytes[17,18]. $InsP_3$ might, therefore, release calcium from intracellular stores in ventral photoreceptors to induce adaptation. The inability of 500 μM EGTA, injected with 100 μM $InsP_3$, to block desensitization may be due to the inability of this amount of EGTA to significantly increase the existing calcium buffering capacity of the cell. Further investigation is needed to determine whether $InsP_3$ directly releases calcium from within the cell.

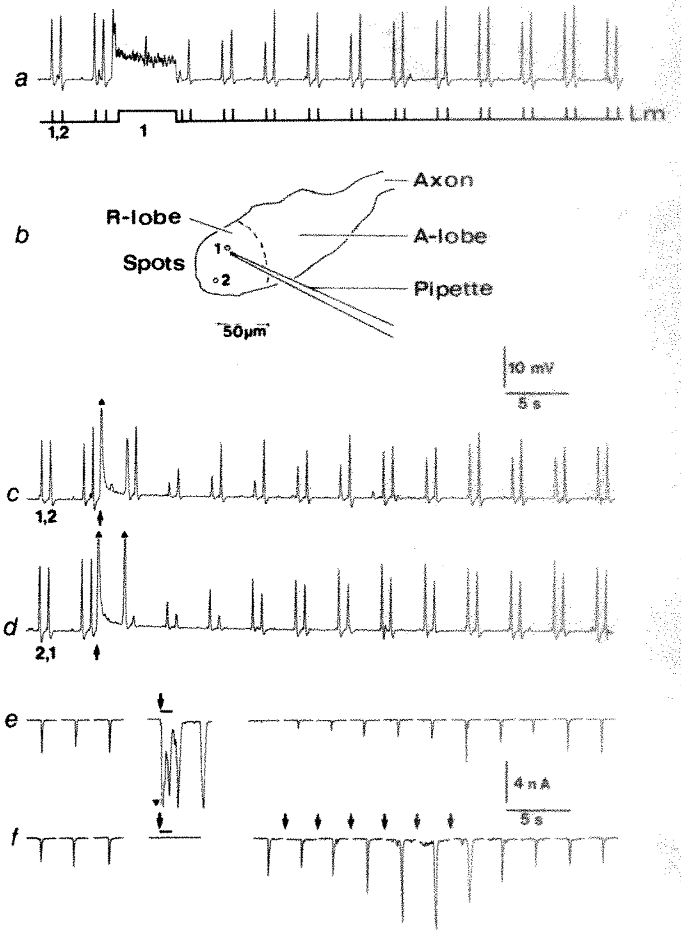

Fig. 3 $InsP_3$-induced desensitization. Localized desensitization was produced both by light (***a***) and by injection of 100 μM $InsP_3$ (***c*** and ***d***) in a cell whose outline is shown in ***b***. In record *a*, the light monitor (Lm) denotes the time of occurrence of the light stimuli at spots 1 and 2. Record *a* demonstrates that light adaptation at spot 1 produces a stronger desensitization of subsequent responses at spot 1 than at spot 2 (ref. 9). Similarly, injection of 100 μM $InsP_3$ at spot 1 produces a greater desensitization of subsequent responses at spot 1 compared with spot 2 (records *c* and *d*). The sequence of light flashes in *c* and *d* was reversed to exclude the possibility that the localized desensitization was in any way related to the sequence in which the two regions of the cell were illuminated. Similar findings were obtained in two other cells with injections of 100 μM $InsP_3$ and in three further cells with 100 μM $InsP_3$ and 500 μM EGTA (see text). The same experiment was performed with 20 μM $InsP_3$; three out of four cells showed a localized desensitization. As controls, four cells were injected with 20 μM $Ins(1,4)P_2$; none showed a localized desensitization. Of six cells injected with 100 μM $Ins(1,4)P_2$, none showed localized desensitization for single injections. Multiple injections, however, did induce a localized desensitization in two of these cells. The voltage-clamp recording in ***e***, from another cell, demonstrates $InsP_3$-induced desensitization of the light response following the excitatory effect of $InsP_3$ injection (arrow). Record *f* demonstrates facilitation of the light response following multiple injections (arrow) of $InsP_3$ into another voltage-clamped cell; in this cell, the electrode was probably in the A-lobe as there was only a slowly developing excitatory effect with each $InsP_3$ injection (not shown). In *e* and *f*, the bars indicate the injection duration; the test flash was 20 ms, the intensity was attenuated by 5.0 log units and the illumination was uniform. A portion of the record between each light response was deleted in *e* and *f* for ease of presentation.

Although $InsP_3$ may adapt the receptor by means of stimulating the release of calcium, it is unlikely that the excitatory effect of $InsP_3$ is mediated solely by a rise in calcium. Ionophoretic injection of calcium does not excite ventral photoreceptors[12]. In addition, we must also explain the correlated opening of the thousands of channels that underlie the $InsP_3$-induced discrete waves and bursts. If these channels open independently of each other then $InsP_3$ must initiate the correlated release of many molecules of another transmitter which opens the individual channels.

If visual excitation and adaptation involve $InsP_3$, one might reasonably expect that the level of $InsP_3$, and of its precursor, phosphatidylinositol-4,5-bisphosphate [$PtdIns(4,5)P_2$], would change during illumination. Light causes a drop in the incorporation of ^{32}P into $PtdIns(4,5)P_2$ of the octopus eye[19] and the 'no receptor potential' (norp A) mutant of *Drosophila* exhibits increased incorporation of ^{32}P into $PtdIns(4,5)P_2$ (ref. 20). Our physiological findings taken together with these biochemical data, suggest an important role for $InsP_3$ in phototransduction.

This research was supported by NIH grants EY01362 and EY03793. We thank Dr Simon Levy for help with the calcium measurements.

myo-inositol polyphosphate may be a messenger for visual excitation in *Limulus* photoreceptors

Photoreceptor excitation begins with the absorption of a photon by rhodopsin and proceeds through an unknown sequence of steps that leads to changes in specific ionic conductances. These conductance changes produce the receptor potential. It has been proposed[1–3] that hydrolysis of phosphoinositides is involved in the control of a variety of physiological processes. Recent studies have implicated inositol 1,4,5-trisphosphate as an intracellular messenger in the cascade mediating hormone-stimulated secretion[4–7]. We propose that one of the steps in the excitatory cascade[8,9] in *Limulus* ventral photoreceptors may be an increase in intracellular concentration of *myo*-inositol polyphosphates, derived from hydrolysis of the membrane component phosphatidylinositol bisphosphate by a phospholipase. Here we present biochemical and electrophysiological evidence that an inositol polyphosphate may be an intracellular messenger in the cascade mediating excitation, based on the following criteria: (1) the cells possess the synthetic and degradative metabolism for the messenger; (2) the natural stimulus leads to a change in the concentration of the messenger within the cells; and (3) intracellular injection of exogenous messenger mimics naturally occurring electrophysiological events.

Limulus ventral rudimentary eyes[10,11] were dissected out of the blood vessels that ensheath them. The cluster of photoreceptor cell bodies at the distal end of the nerve was assayed for the effects of illumination on phosphoinositide metabolism. Steady illumination increased the incorporation of $^{32}PO_4$ and ^3H-inositol into phosphatidylinositol (compare the light/dark ratio for paired ventral eyes, Table 1). However, the amount of ^3H-inositol incorporated into phosphatidyl inositol bisphosphate ($PtdInsP_2$) decreased with steady illumination while there was no effect on $^{32}PO_4$ incorporation (Table 1). Fisher and Agranoff[12] reported a similar finding from synaptosomes in

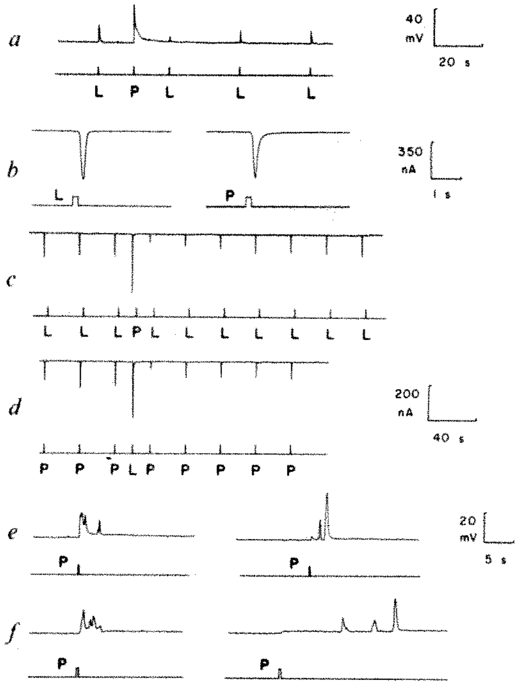

Fig. 1 Electrophysiological effects of intracellular injections of inositol polyphosphates. *Limulus* ventral photoreceptors were impaled with either one micropipette to measure membrane voltage[35] or two micropipettes to measure voltage-clamp currents[36,37]. The electrodes were inserted into the rhabdomeric lobe except where noted. The lower of each pair of traces is a monitor for stimuli: L denotes illumination. Injections (denoted P) were made by applying pressure to the back of the micropipette. *a*, Membrane voltage recorded from an electrode filled with 400 μM $Ins(1,4,5)P_3$ plus 200 mM KCl. Light intensity 3×10^{-7} W cm^{-2}. Pressure injections of $Ins(1,4,5)P_3$ induced large depolarizations and attenuated the subsequent responses to illumination. *b–d*, Currents recorded by a voltage clamp. *b*, Light stimulus 2.1×10^{-5} W cm^{-2}, duration 200 ms. *c*, Note that pressure injection of $Ins(1,4,5)P_3$ induced an inward current and desensitized the light response (light intensity 1.3×10^{-6} W cm^{-2}). *d*, Conversely, light (1.3×10^{-3} W cm^{-2}) desensitized the response of the photoreceptor to the injection of $Ins(1,4,5)P_3$ (same scales for *c* and *d*). Records *a–d* were from the same cell. *e, f*, Membrane voltage recorded by micropipettes filled with 400 μM $Ins(1,4)P_2$ in each of two cells. The left-hand records were obtained with the micropipettes placed in the rhabdomeric lobe; the right-hand records were obtained with the micropipette placed near the rhabdomeric lobe (in *e*) and far from the rhabdomeric lobe (in *f*). Note that the $Ins(1,4)P_2$-induced depolarizations appear to be summated 'discrete events'[21,22] and are more delayed when the injection pipette is impaled farther from the rhabdomeric lobe (same scales for *e* and *f*).

Table 1 Effect of light on the incorporation of labelled precursors into phosphoinositides

	Precursor	Product	Total d.p.m. radioactivity (mean ± s.e.m.) Light	Dark	Ratio light/dark per animal (mean ± s.e.m.)	*P* value for ratio
a	^{3}H-inositol	InsP$_3$	930 ± 157	563 ± 122	1.76 ± 0.22	0.005 (25)
b	^{3}H-inositol	PtdIns	3,660 ± 388	3,232 ± 345	1.20 ± 0.09	0.05 (10)
	^{3}H-inositol	PtdInsP	344 ± 56	456 ± 50	0.84 ± 0.16	>0.1 (10)
	^{3}H-inositol	PtdInsP$_2$	1,928 ± 262*	3,001 ± 289*	0.66 ± 0.09	0.01 (10)

	^{32}PO$_4$	PtdInsP	710 ± 183	546 ± 57	1.46 ± 0.45	>0.4 (10)
	^{32}PO$_4$	PtdInsP$_2$	3,466 ± 545	3,425 ± 411	1.01 ± 0.17	>0.5 (10)

a, Isolated ventral eyes were incubated on three separate occasions in the dark at 21 °C for 6–8 h in *Limulus* serum containing [2-^{3}H]-inositol (300–500 μCi ml^{-1}). Each ventral eye was washed twice with artificial seawater[23]. One ventral eye of each pair was exposed to light (1–3×10^{-3} W cm^{-2}) for 30 s, followed immediately by the addition of chloroform/methanol (1:2, v/v). The dark-maintained ventral eye from the same animal was extracted in the same way. Water-soluble inositol phosphates were separated by either ion-exchange chromatography[28] or TLC on PEI cellulose[29] and counted for radioactivity. Statistical comparisons were made between the ventral eyes from the same animal using a paired Student's *t*-test. *b*, Each isolated ventral eye was incubated in 0.1 ml *Limulus* serum containing [2-^{3}H]-inositol (500 μCi ml^{-1}) and ^{32}PO$_4$ (250 μCi ml^{-1}) in light or dark at 21 °C for 3 h. The incubation was stopped by adding 2 ml of chloroform/methanol/HCl (100:100:6, by vol.), followed by 0.3 ml of 0.2 M HCl. The lower phase was evaporated to near dryness. Phospholipids were separated by TLC using silica gel HR plates in a solvent system of chloroform/methanol/methylamine (40%)/water (60:36:5:5, by vol.). Areas that contained ^{32}P were identified by autoradiography on X-ray film, scraped off and counted. When the total radioactivities from each group were averaged, only those dark/light values marked by an asterisk were significantly different (at the 0.02 confidence level, two-tailed *t*-test). These data are confounded by large between-animal variations. To minimize the effects of these variations, comparisons of light–dark differences in the incorporation of label were made between the ventral eyes isolated from the same animal, using a paired Student's *t*-test (the number of pairs is given in parentheses).

which acetylcholine stimulated ^{32}PO$_4$ incorporation into phosphatidylinositol but reduced the incorporation into polyphosphoinositides. In addition, Yoshioka *et al.* (in *Octopus*)[13] and Vandenberg and Montal (in squid)[14] have shown that light causes a reduction of ^{32}PO$_4$ incorporation into polyphosphoinositides in preparations of broken photoreceptor cells. We interpret our findings as evidence that phosphoinositides are synthesized in the photoreceptor cells and that the turnover of phosphatidylinositol is increased by illumination, but that the pool of PtdInsP$_2$ is reduced due to enzymatic release of inositol trisphosphate (InSP$_3$) into the cytosol. We found that dark-adapted *Limulus* ventral eyes contained InsP$_3$ and that the content of InsP$_3$ was increased by illumination (Table 1). Taken together, these data show that *Limulus* ventral eyes contain metabolic mechanisms for the synthesis of polyphosphoinositides and for the light-induced increase in the concentration of InsP$_3$. Therefore, *Limulus* photoreceptors contain the metabolic mechanisms necessary for the synthesis of the putative excitatory messenger, InsP$_3$.

We examined the electrophysiological effects of intracellular injection of inositol phosphates into single *Limulus* ventral photoreceptors. Photoreceptors whose cell bodies are isolated from neighbouring photoreceptor cell bodies are found scattered along the ventral eye nerve[15,16]. The adhering glia and axons were peeled away from these cells by the procedure of Stern *et al.*[17]. The location of the rhabdomeric lobe of a peeled cell can usually be identified visually; the rhabdomeric lobe is the region of the cell that contains most of the rhodopsin[18] (G. Murray, personal communication) and which shows the maximum sensitivity to light[17]. It is the region of the cell in which both excitation and adaptation occur[17,19].

The rhabdomeric lobe was impaled with a micropipette containing InsP$_3$ (0.004–0.4 mM). The location of the micropipette was viewed using an IR television camera. Successful intracellular injection of a solution caused a local disturbance in optical transmission through the cell, which could be observed on a television monitor[20]. Brief pressure injections of the InsP$_3$ solution elicited a depolarization (in 48 cells) that resembled the response of the cell to a flash of light (Fig. 1*a* and Table 2). Moreover, brief injections of InsP$_3$ elicited an inward positive membrane current measured by a voltage-clamp technique (19 cells) (Fig. 1*b*). Injections of some samples of InsP$_3$ elicited responses that appeared to be the summation of discrete events[21,22] (28 cells) (Table 2); injections of other samples most often elicited smooth responses. The causes of these differences between samples of InsP$_3$ are unknown. Injection of InsP$_3$ was found to cause a subsequent decrease in the sensitivity of the photoreceptor to light (Fig. 1*a*, *c*). Furthermore, light caused a subsequent attenuation in the responses elicited by repetitive injections of InsP$_3$ (22 cells) (Fig. 1*d*), that is, light caused an apparent adaptation of the responses elicited by InsP$_3$ (and vice versa). Injection of InsP$_3$ into the cell at some distance from the rhabdomeric lobe sometimes elicited little or no smooth depolarization (or smooth inward positive membrane current), sometimes elicited delayed, summated discrete events such as those evoked by the absorption of a small number of photons[21,22], but often led to a profound desensitization of the cell.

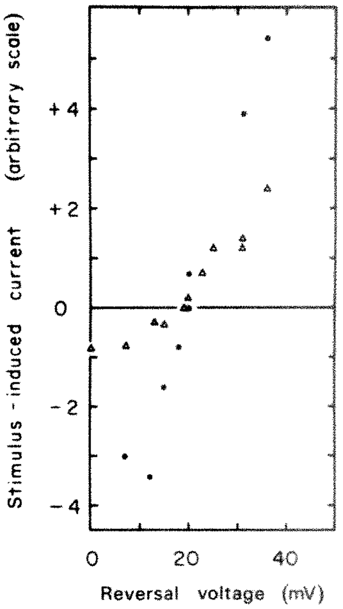

Fig. 2 Reversal voltages of light-induced and Ins(1,4,5)P$_3$-induced currents. The amplitude of currents recorded by a voltage clamp are plotted against membrane voltage. Note that the two nonlinear curves cross the zero-current axis at approximately the same voltage; that is, the reversal voltage for light-induced currents (●) is approximately the same as that for Ins(1,4,5)P$_3$-induced currents (△).

Injection of inositol 1,4–bisphosphate [Ins(1,4)P$_2$] or inositol 4,5-bisphosphate [Ins(4,5)P$_2$] (Table 2) into the rhabdomeric lobe of *Limulus* photoreceptors also induced transient depolarizations. These responses sometimes appeared to be identical to

Table 2 Effects of intracellular injections of *myo*-inositol phosphates

Substance injected	Effect Smooth depolarization or inward current	Discrete events	Total number of cells
400 µM Ins(1,4,5)P_3* (Irvine; human red cell ghosts)	+++ (19)	+ (1)	20

The concentrations of compounds shown were those contained in the injection pipettes. The volumes of injections were estimated to be always less than 1% of the cell volume. For each compound, the person who prepared the substance and the source used are given. The numbers in parentheses are the number of cells from which each type of event was observed; some cells showed both types of events. The number of 'plus' signs indicates the relative efficacy of the injections; – indicates no effect.

* Potassium salt prepared as described by Streb *et al.*[5].

† Potassium salt prepared by the method of Grado and Ballou[30] as modified by Irvine *et al.*[31]. All three inositol polyphosphates were checked for purity (>99%) and identified by iontophoresis[32].

‡ Potassium salt prepared by mild alkaline hydrolysis[33] of phosphatidylinositol-4,5-bisphosphate, followed by oxidation with periodate and treatment with 1,1-dimethylhydrazine[34].

§ Ratio of Ins(1,4,5)P_3 to Ins(2,4,5)P_3 was 3:1.

‖ Material that had been eluted from the same paper chromatogram on which InsP_3, Ins(1,4)P_2 and Ins(4,5)P_2 were separated but which did not contain inositol polyphosphates.

¶ These injections did not induce responses such as those shown in Fig. 1, but did produce small, often irreversible depolarizations that we attribute to either artefacts of the injection procedure or cell damage.

# Potassium salt; ** cyclohexylammonium salt; †† sodium salt.

those induced by InsP_3 injections but more often appeared to be the summation of discrete events (Fig. 1*e*, *f*). The responses induced by injections of inositol bisphosphate into a region of the cell not containing rhabdomere were more delayed (Fig. 1*e*, *f*); the delay qualitatively depended on the apparent distance between the injection micropipette and the rhabdomeric lobe of the cell. Responses induced by injections of inositol bisphosphate also apparently could be adapted by light, and vice versa.

It is difficult to estimate the intracellular concentration of inositol polyphosphates that is necessary to induce the physiological events that we describe, for two reasons. First, the amplitude of the injection-induced responses depends strongly on the location of the pipette within the cell, for both InsP_3 and InsP_2 compounds. Second, the details of diffusion from the tip of the injection pipette to the site or sites of action are unknown. For the same reasons, it is difficult to compare quantitatively the efficacy of different compounds or solutions of the same compounds at different concentrations.

The injection of DL-inositol 1-phosphate into the rhabdomeric lobe had no noticeable effect on the cell (Table 2). For each of these cells, InsP_3 was injected from a second pipette placed close to the pipette containing inositol-1-phosphate, to verify that the cell responded. Also, the injection of inositol hexaphosphate (phytic acid, InsP_6) had no noticeable effect on the cells (Table 2).

A stringent criterion for a putative messenger for excitation is that it must change the same specific ionic conductances as light. We tested InsP_3 according to this criterion by measuring the reversal voltages for both light-induced currents and InsP_3-induced currents; Fig. 2 shows that the reversal voltages were very similar. In five cells, the reversal voltages did not differ by more than 5 mV. Moreover, in one cell the reversal voltages for both light-induced currents and InsP_3-induced currents were measured at each of two concentrations of extracellular Na^+ (425 mM and 106 mM, sucrose replacing NaCl)[23]; in each solution, the reversal voltages differed by 4 mV. Thus, injection of InsP_3 into the rhabdomeric lobe mimics several of the electrophysiological effects of a flash of light. We note that responses with the properties shown in Figs 1 and 2 are not induced by intracellular iontophoretic injections of calcium ions[24], or pressure injections of EGTA[25], ATP, cyclic AMP, GTP, cyclic GMP[26], or *p*H buffers[27].

Our biochemical and electrophysiological findings, reported here, are consistent with some criteria for the identification of InsP_3 as an authentic messenger for excitation in *Limulus* ventral photoreceptor cells. Our electrophysiological evidence also is consistent with an inositol bisphosphate or glycerol-1-phosphoinositol-4,5-bisphosphate being an excitatory messenger; the biochemistry necessary to test these compounds is incomplete at present. We do not yet know whether the magnitude or the kinetics of the light-induced changes in either the concentrations or the turnover rates of the intracellular inositol polyphosphates is consistent with the hypothesis; nor do we know whether the inositol bisphosphates have direct actions in the excitation process or cause a change in InsP_3 concentration, or have some other action on the cell's metabolism. Therefore, we tentatively suggest that light leads to the release of an inositol polyphosphate by the hydrolysis of PtdInsP_2 in the membranes of the photoreceptors; the inositol polyphosphate is diffusible within the cytosol and is one messenger in the cascade of excitation.

We thank Drs S. R. Bolsover, G. D. Fischbach, J. Korenbrot, P. W. Majerus, B. M. Salzberg and W. R. Sherman for helpful discussions; Dr W. R. Sherman for a gift of DL-inositol-1-phosphate and Dr C. E. Ballou for gifts of glycerol-P-Ins(4,5)P_2 and authentic inositol phosphates; and Dr R. Sundler for a preprint of his description of the PEI chromatographic system. The work was supported by NIH grants EY-01914 and EY-05166 to J.E.B., and EY-00871 and EY-04149 to R.E.A.

Alternative sets of DNase I-hypersensitive sites characterize the various functional states of the chicken lysozyme gene

The structural organization of chromatin is thought to determine the state of differentiation and activity of eukaryotic genes. Local interruptions of the regular nucleosomal array, the so-called DNase-hypersensitive sites, may indicate regions of the genome which play a critical part in regulation of differential gene activity[1–4]. We present here two new observations on the chromatin structure of the chicken lysozyme gene, which strongly support a regulatory function for these sites. First, different sets of DNase I-hypersensitive sites have been found upstream from the promoter, depending on whether the gene is constitutively expressed (cultured macrophages) or in the steroid hormone-controlled state (oviduct). It seems, therefore, that diverse modes of regulation of the same gene are associated with discrete patterns of DNase I hypersensitivity. Second, one of the DNase I-hypersensitive sites in the oviduct chromatin disappears and reappears on steroid hormone withdrawal and secondary induction. These reversible changes in a narrow chromatin region reflect the transition from the potentially active to the active state of the lysozyme gene.

Nuclease hypersensitivity in chromatin involves short regions of approximately 50–400 base pairs that are roughly one order of magnitude more susceptible to nuclease cutting than is active chromatin as a whole[1–5]. These regions are generally referred to as DNase-hypersensitive sites[4] and have mostly been localized to the region near the 5′ end of actively transcribed genes. Genes which are subject to complex regulatory mechanisms, such as developmentally controlled genes[5–7] or genes under hormonal control[7–9], often display a more complex pattern of DNase hypersensitivity with multiple sites upstream and downstream from the gene.

The chicken lysozyme gene offers attractive features for studying the role of chromatin structure in activation and inactivation of a eukaryotic gene. In the chicken oviduct, synthesis of lysozyme mRNA is under the control of steroid hormones[10] and can be reversibly induced in immature chickens by oestrogen administration or withdrawal[11]. Expression of the same lysozyme gene in mature chicken macrophages is constitutive and transcription proceeds from the same promoter at a relatively low rate (ref. 12 and our unpublished S_1-mapping experiments). Liver cells, like most other cell types in the organism, do not express lysozyme mRNA (data not shown). It was conceivable that the chromatin might be organized differently depending on whether the cell in question is steroid hormone-responsive, nonresponsive or dormant.

We examined the chromatin structure of a 7.1-kilobase(kb) *Eco*RI fragment containing 4.6 kb of DNA sequences upstream from the promoter of the chicken lysozyme gene, the first two exons and part of the second intron (see scheme in Fig. 3). Previously, we demonstrated that in the mature oviduct of egg-laying hens this region is marked by three hypersensitive sites referred to as HS3, HS4 and HS5 (ref. 8). As subsequent investigations have revealed a more complex pattern, we have re-named them according to their position with respect to the promoter of the gene (in kb) as HS − 2.4, HS − 1.9 and HS − 0.1. Potentially active genes are often found to have hypersensitive sites independent of the transcription process *per se*[3,4,7]. We therefore anticipated that only some of the sites upstream of the lysozyme gene might appear and disappear in correlation with steroid-mediated control of the transcriptional activity of the gene. To investigate this possibility, nuclei were prepared from the oviducts of immature chickens induced for 3 and 12 days with diethylstilboestrol, a synthetic oestrogen (primary induction). The small amount of oviduct cell mass in uninduced chickens precluded an assay for hypersensitive sites in birds with induction periods shorter than 3 days. Nuclei were mildly digested to varying extents by DNase I. DNA was then isolated and digested with *Eco*RI and analysed by the Southern blot technique using an indirect end-labelling procedure[13,14]. After 3 days of exposure to oestrogen, the three sites HS −2.4, HS −1.9 and HS −0.1, characteristic of the mature oviduct of the egg-laying hen, are fully established and do not change during an additional 9-day period of primary induction (Fig. 1). If hormone administration is interrupted after 11 days, one of the hypersensitive sites (HS −1.9) disappears; on secondary induction with the oestrogen analogue it reappears. Thus, a close correlation can be demonstrated between the presence of the steroid hormone and the formation of the DNase I-hypersensitive site about 1.9 kb upstream of the transcriptional start site of the gene[15]. A similar observation was made in the chromatin of the vitellogenin gene[7]. The formation of a particular chromatin structure at a position far upstream appears to be associated with oestrogen activation of transcription. The site at −1.9 kb may be due to binding of the hormone–receptor complex, or to other DNA-binding proteins related to steroid action.

The hypersensitive site at −0.1 kb is only slightly less prominent 6 days after hormone withdrawal, indicating that the promoter region does not show considerable structural changes in response to the varying extents of oestrogenic induction and withdrawal.

To gain more information about functional aspects of the chromatin structure, we performed a second set of experiments in which the chromatin pattern was examined in various tissues of the egg-laying hen which do or do not express lysozyme (Fig. 2). The most striking result is that there are marked differences in the structural organization of chromatin between nuclei from two lysozyme-producing cell types. In mature macrophages, which constitutively express the gene, neither of the oviduct sites HS −1.9 or HS −2.4 is present; instead two new sites, HS −0.7 and HS −2.7, can be seen. This finding shows for the first time that different modes of transcriptional regulation of a eukaryotic gene correlate with different chromatin structures and supports the notion that the chromatin structure itself determines the functional state of a gene. The result further supports our finding that HS −1.9 is involved in steroid-dependent gene expression, as it is obviously not used for constitutive expression of the lysozyme gene. The formation of HS −1.9, however, cannot be the result of the mere presence of a functional oestrogen receptor complex because in liver, an oestrogen target organ[7], this hypersensitive site is not formed (Fig. 2).

The hypersensitive site immediately upstream of the cap site, HS −0.1, is only present in cells which either express or have the potential to express the lysozyme gene (Figs 2 and 3). In tissues which do not express the lysozyme gene, the promoter region is buried within an inaccessible chromatin structure.

The hypersensitive site HS −2.4 is present in oviduct, liver, kidney, brain and in 5-day-old embryos, but is absent in macrophages and erythrocytes. There is no obvious function which correlates with this hypersensitive site. Based on its

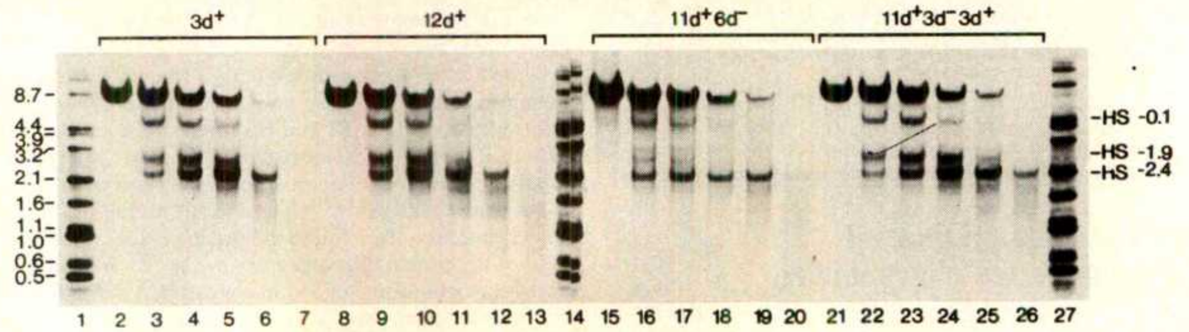

Fig. 1 Mapping of DNase I-hypersensitive sites in the 5′ flanking region of the lysozyme gene in oviducts of diethylstilboestrol-induced, deinduced and reinduced immature chickens. Silicon tubes filled with crystalline diethylstilboestrol (DES) were implanted subcutaneously in 5-week-old female chickens[17]. Groups of chickens were either killed 3 and 12 days after implantation or hormone was withdrawn by removal of the tubes after 11 days. After 3 days of hormone withdrawal, one group of chickens was injected with 2 mg DES in sesame oil (secondary stimulation) while control chickens remained uninduced. Reinduced chickens and those in which hormone was withdrawn were killed 6 days after the start of the withdrawal period. Oviduct nuclei were prepared as described previously[8] except that 2 mM EDTA and 0.5 mM EGTA were present in the isolation buffers. Digestion was with increasing concentrations of DNase I. Nuclear DNA was then isolated and completely digested with *Eco*RI. Southern blots were probed with radioactively labelled nick-translated plasmid DNA containing sequences between *Hin*dIII sites 4 and 5 (ref. 18) essentially as described previously[8]. The autoradiograph shows oviduct hypersensitive sites on the *Eco*RI fragment E4E5 (compare with scheme in Fig. 3) from 3-day-induced (3d$^+$, tracks 2–7), 12-day-induced (12d$^+$, tracks 8–13), 11-day-induced plus 6 days' hormone withdrawal (11d$^+$6d$^-$, tracks 15–20), and 11-day-induced/3 days' hormone withdrawal/3-day-reinduced (11d$^+$3d$^-$3d$^+$, tracks 21–26) chickens. Tracks 1, 14 and 27 show DNA size markers, their length indicated in kb. The same results as seen in tracks 15–26 were obtained when oviduct chromatin was mapped from 12-day-induced followed by 3 or 6 days' hormone withdrawal, chickens (12d$^+$3d$^-$, 12d$^+$6d$^-$) and from 12-day-induced, 6 days' withdrawal, 3-day-reinduced chickens (12d$^+$6d$^-$3d$^+$, data not shown). Hypersensitive sites (HS) were named according to their approximate location upstream of the cap site of the gene (in kb).

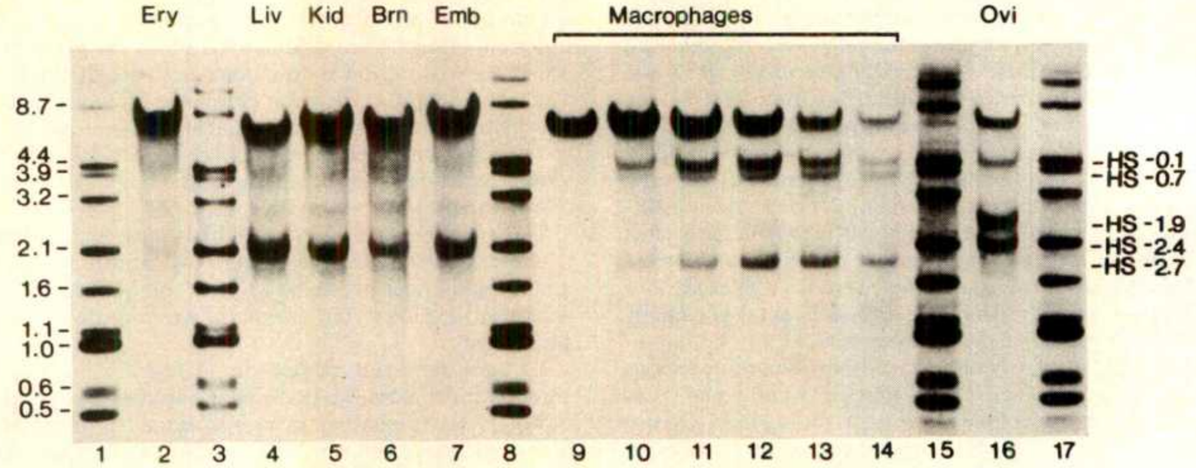

Fig. 2 Mapping of DNase I-hypersensitive sites in the 5′ flanking region of the lysozyme gene in various lysozyme-producing and -nonproducing tissues of egg-laying hens and in tissue of total embryos. The autoradiograph shows hypersensitive sites mapped in nuclear chromatin of erythrocytes (track 2), liver (track 4), kidney (track 5), brain (track 6), mature oviduct (track 16) and whole 5-day-old embryos (track 7). Tracks 9–14 show the pattern obtained when nuclear chromatin of mature macrophages was mapped with increasing concentrations of DNase I. Mapping was done in all cases as described previously[8]. Tracks 1, 3, 8, 15 and 17 show DNA size markers (in kb). Macrophages were obtained from cultured white blood cells. Blood was collected by heart puncture and the buffy coat separated by centrifugation at 800g for 10 min through a Ficoll solution (lymphocyte separation medium, density 1.077; Flow) and seeded at 1×10^8 cells per 150 cm^2 flask in growth medium (MEM-Iscove; 8% fetal calf serum, 2% chicken serum; Boehringer). The adherent cell fraction was scraped off after 5 days and lysed by Dounce homogenization at 2×10^7 cells ml^{-1} in homogenization buffer[8] modified as described in Fig. 1 legend.

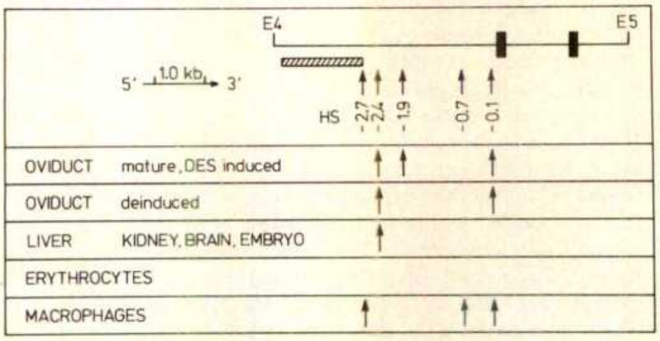

Fig. 3 Scheme showing the positions of DNase I-hypersensitive sites in the 5′ flanking region of the lysozyme gene in various chicken tissues. E4 and E5 denote relevant *Eco*RI sites 4.6 kb upstream and 2.5 kb downstream of the promoter of the gene[18]. Solid boxes represent exon regions and the hatched bar shows the position of the subcloned *Hin*dIII fragment (H4H5 in ref. 18) used as radioactive probe in the procedure for mapping DNase I-hypersensitive sites. Arrows indicate the positions of hypersensitive sites as shown in Figs 1 and 2.

absence or presence in the various tissues, we propose that HS −2.4 has a role in suppressing lysozyme gene activity. Such a function should not be present in macrophages which express the lysozyme gene constitutively, but would be required in the oviduct, in which transcription occurs in a reversible fashion depending on the hormonal state. In the latter case, the steroid-inducible site HS − 1.9 would override the presumed function of HS −2.4.

Implicit in our interpretation is the assumption that the upstream hypersensitive sites are involved in the control of the lysozyme gene itself rather than being indicative of a yet unidentified adjacent transcription unit. As *in vitro* transcription analyses of the respective DNA sequences revealed transcripts starting only at the lysozyme promoter (M. Theisen, unpublished), we feel this bias to be tenable.

DNase I-hypersensitive sites are believed to be short nucleosome-free regions which mark sites where regulatory proteins gain access to specific DNA sequences[16]. Evidence is accumulating that these structures not only signal the actual transcriptional state of a gene but also the state of differentiation. The correct formation of these structures during differentiation seems to be crucial for differential expression. It remains to be shown how chromatin structural changes observed kilobases away from the transcriptional initiation point can determine the state of differentiation and activity of a eukaryotic gene.

High rates of *in vitro* synthesis of 1,4-*β*-D-glucan in cell-free preparations from *Phaseolus aureus*

T. Callaghan & M. Benziman

Department of Biological Chemistry, Institute of Life Sciences,
The Hebrew University of Jerusalem, 91904 Jerusalem, Israel

Progress in the study of biosynthesis of cellulose (1,4-*β*-D-glucan) has been persistently hampered by the low rates of *in vitro* synthesis obtained using cell-free preparations derived from plant or bacterial cells capable of ample cellulose synthesis *in vivo*[1]. We recently reported the achievement of high rates of synthesis of 1,4-*β*-D-glucan from UDP-glucose, using membrane preparations obtained from the bacterium *Acetobacter xylinum*. The key to the success lay in the discovery of a complex GTP-Ca^{2+}-protein factor-mediated regulatory system for the *A. xylinum* UDP-glucose-*β*-D-glucosyltransferase (cellulose synthase)[2,3]. We now describe conditions found for an extremely efficient transfer of glucose from UDP-glucose to a cellulosic 1,4-*β*-D-glucan product using enzyme preparations derived from a higher plant, seedlings of mung beans (*Phaseolus aureus*). The rates of enzyme activity achieved approach those of cellulose synthesis observed *in vivo*.

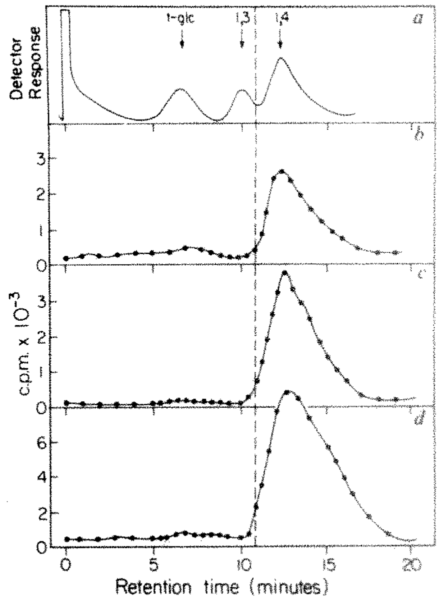

Fig. 1 Gas liquid chromatography of permethylated derivatives of the ^{14}C-labelled-24% KOH-insoluble product formed from UDP-[^{14}C]glucose. *a*, Recorder tracing of derivatives obtained from a mixture of laminarin and cellobiose. Peaks were identified by comparison with derivatives of the individual compounds (1,3 = permethylated derivative of laminarin; 1,4 = permethylated derivative of cellobiose; t-glc = terminal glucose). The lower three curves represent elution profiles of radioactivity of permethylated derivatives from products formed in standard assay mixtures, 5 μM (*b*), 500 μM (*c*) and 1 mM UDP-[^{14}C]glucose (*d*).

In all the studies described here, data are presented only for the radioactive 24% KOH-insoluble glucan product formed from UDP-[^{14}C]glucose, which has been characterized as 1,4-*β*-D-glucan by the following criteria: (1) Total acid hydrolysis converted >90% of the radioactivity to ^{14}C-glucose. (2) The product was more than 95% digested by either highly purified *Trichoderma reesei* exocellobiohydrolase or by highly purified *Trichoderma* endo-1,4-*β*-glucanase (on chromatography of the exocellobiohydrolase digest, on Whatman No. 4 paper in *n*-propanol/ethyl acetate/water, 7:1:2, v/v, >80% of the soluble radioactivity co-chromatographed with a cellobiose standard and the remainder was found at the origin and in glucose). (3) Methylation analysis[2] of the products formed either from 5 μM, 500 μM or 1 mM UDP-glucose, yielded exclusively 1,4,5-trioctyl-2,3,5-tri-*O*-methyl-[^{14}C]glucitol, the derivative expected for 1,4-linked glucosyl moieties (Fig. 1). (4) periodate oxidation[4], followed by borohydride reduction, complete acid hydrolysis and paper chromatography yielded primarily erythritol (indicative of 1,4-linkages), a trace of glycerol and some material which remained at the origin. In no case could a significant peak of glucose (indicative of 1,3-linkages) be detected. The small peak of glycerol detected amounted to 1–3% of the labelling of the major erythritol peak. Assuming that this glycerol arises from terminal glucose residues, it indicates that the enzyme is producing long chains and is not a chain-terminating enzyme adding just single glucose residues to pre-existing polysaccharides.

The procedure for preparing the enzyme is summarized in Fig. 2. If cells were ruptured in an extracting medium containing 20% polyethylene glycol 4000 (PEG), the membranes and all associated glucan synthase activity (when assayed under standard assay condtions, see below) pelleted at relatively low centrifugal forces (12,000*g* for 10 min). In contrast, in the absence of PEG, higher centrifugal forces (150,000*g* for 60 min) were needed to sediment membranes and the enzyme activity. A similar effect of PEG has been observed with other plant glucan synthases[1] and with *A. xylinum* 1,4-*β*-D-glucan synthase[2],

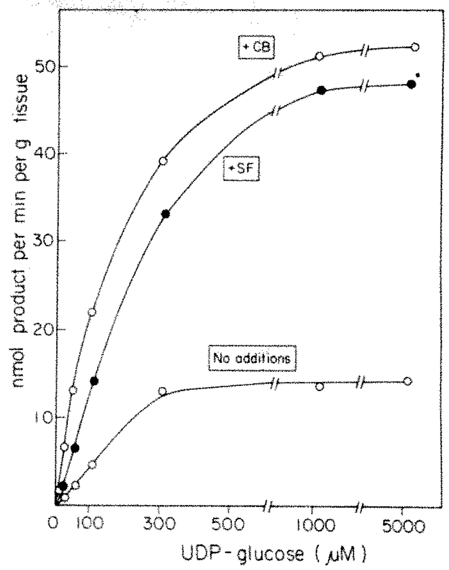

Fig. 3 The effect of varying the concentration of UDP-glucose on enzyme activity. UDP-glucose concentrations were as indicated, and membrane fraction derived from 10 mg fresh weight of tissue (0.04 mg protein) was used per assay. Additions indicated were: 5 mM cellobiose (+CB) and 25 μl of supernatant fraction (+SF).

and may be attributed to the known effect of PEG in promoting membrane fusion and protein coagulation[5]. PEG treatment also enhanced 4–5-fold, the rate of product formation by the membrane preparation. This effect could involve protection of the enzyme during cell breakage and/or promotion of interaction of enzyme subunits. Activity was retained in PEG preparations for two months when these were frozen in liquid nitrogen and kept at −70 °C.

Standard assays performed at 20 °C contained in a final volume of 0.2 ml: 50 mM *N*-(2-hydroxyethyl)-piperazine-*N'*-3-propanesulphonic acid buffer, *p*H 7.5, 5 μM UDP-[^{14}C]glucose (320 c.p.m. pmol^{-1}), 6 mM $MgCl_2$, 4 mM $CaCl_2$, 5 mM cellobiose and enzyme. Reactions were terminated by addition of 2 ml 24% KOH. Aproximately 20 mg of carrier cellulose was added, and the mixture incubated for 12 h at 40 °C (ref. 6). The mixtures were then filtered onto Whatman GF/A glass fibre filters, and washed consecutively with water and methanol. The filters containing alkali-insoluble product were dried and counted. Under these conditions, reactions were linear with time for up to 30 min and proportional to enzyme concentration up to 100 μg protein. At *p*H 8.6, activity was considerably lower and linearity with time ceased after 2–5 min.

Requirements for the reaction are shown in Table 1. The enzyme has an absolute requirement for both Mg^{2+} and Ca^{2+}. Whereas the dependence on Mg^{2+} was demonstrable with regular enzyme preparations, the effect of Ca^{2+} was much more pronounced when EGTA was included in the medium used for extracting the enzyme. The particulate membrane fraction sedimenting from centrifuged crude homogenates exhibits low activity. Activity is restored on re-addition of the supernatant fraction (SF). The supernatant alone was found to contain no synthase activity (data not shown). Product formation is markedly increased by the addition of cellobiose to the incubation mixture. However, the extent of this effect is dependent on the enzyme preparation. Whereas addition of cellobiose to centrifuged fractions results in a tenfold increase in activity, in the presence of the SF only a twofold increase is observed. Activity of the particulate fraction increases with increasing cellobiose concentrations and with varying levels of SF. Half-maximal stimulations are achieved with 0.75 mM cellobiose and 1.5 μl of SF (an amount of supernatant derived from 0.8 mg fresh weight of tissue). The enzyme displays normal Michaelis–Menten kinetics with respect to UDP-glucose (Fig. 3). The presence of saturating amounts of cellobiose or SF does not alter the apparent K_m for the substrate (100 μM) but the V_{max} is enhanced about fivefold (compare refs 7 and 8). Preliminary characterization of the stimulatory factor in SF, based on stability studies, indicate that it is an organic dialysable, alkali-labile compound which is absorbed by charcoal. It is resistant to heat and acid treatment (0.1 M HCl, 10 min at 100 °C) and to digestion by exocellobiohydrose, endo-1,4-*β*-glucanase, *β*-glucosidase, crude cellulase and alkaline and acid phosphatases. Unlike the 1,4-*β*-glucan synthase of *A. xylinum*[2], the plant enzyme has not been found to respond to the addition of GTP. The SF, however, strongly interferes with GTP activation of the bacterial enzyme.

Table 1 Factors affecting UDP-glucose: 1,4-*β*-D-glucan synthase activity

Incubation mixture	Activity (pmol product per min per g tissue)
Complete system	1,700
Minus Mg^{2+}	50
Minus Ca^{2+}	40
Minus SF minus cellobiose	170
Minus cellobiose	850
Minus SF	1,700
Plus DCB (6 μM)	120
Plus coumarin (2 mM)	40

The complete system contains: crude homogenate derived from 10 mg of tissue in the presence of 5 mM EGTA; 6 mM $MgCl_2$; 4 mM $CaCl_2$; 5 mM cellobiose; and 5 μM UDP-[^{14}C]glucose. DCB = 2,6-dichlorobenzonitrile.

Incorporation of labelled glucose from UDP-[^{14}C]glucose into the cellulosic product was neither stimulated nor inhibited by the addition of an up to 100-fold excess of unlabelled UDP-xylose or GDP-glucose (compare refs 6, 9–11). Coumarin and dichlorobenzonitrile, specific inhibitors of plant *in vivo* cellulose synthesis[12] strongly inhibit our enzyme (Table 1). Note that these compounds inhibit GTP activation of the *A. xylinum* 1,4-*β*-glucan synthase (Y. Aloni and M.B., unpublished results).

Because the reaction product is clearly a 1,4-*β*-D-glucan, we presume that we are dealing with a true cellulose synthase; however, lacking information on the crystalline structure and microfibrillar nature of the product, we referred to it at present simply as a 1,4-*β*-D-glucan synthase. The rates of synthesis of 1,4-*β*-glucan *in vitro* reported here far exceed those previously reported[13–17], and approach those of cellulose synthesis observed *in vivo* during primary cell wall formation (12–30 nmol per min per g fresh weight of tissue)[15,17,18]. Thus, the long awaited goal of obtaining from a plant source a highly active system for 1,4-β-D-glucan synthesis *in vitro* has been accomplished. This system with its interesting properties, especially in relation to the bacterial synthase system, should be of great value for exploring further the details of the mechanism and regulation of cellulose synthesis.

6 Å-Resolution X-ray structure of a variable surface glycoprotein from *Trypanosoma brucei*

D. M. Freymann, P. Metcalf, M. Turner* & D. C. Wiley

Department of Biochemistry and Molecular Biology,
Harvard University, Cambridge, Massachusetts 012138, USA
* MRC Biochemical Parasitology Unit, The Molteno Institute,
Downing Street, Cambridge CB2 3EE, UK

The variable surface glycoprotein (VSG) is the predominant component of the surface coat of the African trypanosome[1]. The expression of antigenically distinct VSGs on minor populations during infection allows the parasite to escape the host immune response[2,3]. Purification of the protein is facilitated by the enzymatic release of a soluble form of VSG (sVSG) which occurs on cell lysis[4]. The soluble form is a dimer with an approximate molecular weight of 120,000–130,000[5]. Partial proteolysis of sVSG[6] reveals a protease-sensitive link between an amino-terminal domain which comprises about two-thirds of the molecule, and a C-terminal domain which contains the membrane attachment site[7]. We have obtained crystals suitable for high-resolution structural analysis from preparations of three sVSG: MITat 1.2, ILTat 1.25 and ILTat 1.22. The crystal structure of the dimer of the MITat 1.2 amino-terminal domain has been solved to 6 Å resolution. We report here that the dimer is an unusual 90 Å rod-like molecule composed of a helical bundle of at least four 80 Å-long α-helices.

sVSG was purified from *Trypanosoma brucei* as described previously[1]. MITat 1.2 was crystallized by vapour diffusion of a 40 mg ml^{-1} solution in 50 mM Tris-HCl/0.1% sodium azide, *p*H 7.5 against 9% polyethylene glycol (PEG) 8000/10% ethylene glycol in the same buffer. Tetragonal bipyramidal crystals, which diffract to 2.9 Å, appear within a week and grow to a maximum dimension of 1 mm. The space group is $P4_12_12$, with $a = 96.3$, $c = 111.3$ Å; the asymmetric unit contains one monomer of the amino-terminal domain. Details of the crystallization of ILTat 1.22 and ILTat 1.25 will be published elsewhere.

Protein recovered from MITat 1.2 crystals has an apparent molecular weight (MW) of 43,000 (43 K) on SDS-polyacrylamide gel electrophoresis (PAGE), co-migrating with the amino-terminal domain identified by Johnson and Cross[6] (Fig. 1). The amino-terminal sequence of the recovered protein is Ala-Ala-Glu-Lys, consistent with the previously published N-terminal sequence[6]. By using 'immuno-blots'[8], (data not shown) we have demonstrated that the protein recovered from the crystal does not contain the C-terminal 'cross-reacting determinant'[9] of the intact VSG. Thus, it seems that adventitious proteolysis from a contaminating protease releases an N-terminal crystallizable domain. On gel permeation HPLC (data not shown) protein recovered from MITat 1.2 crystals elutes with an approximate molecular weight of 80,000, clearly distinguishable from the intact native dimer at around 120,000, suggesting that the crystalline protein is a dimer of two 43K domains.

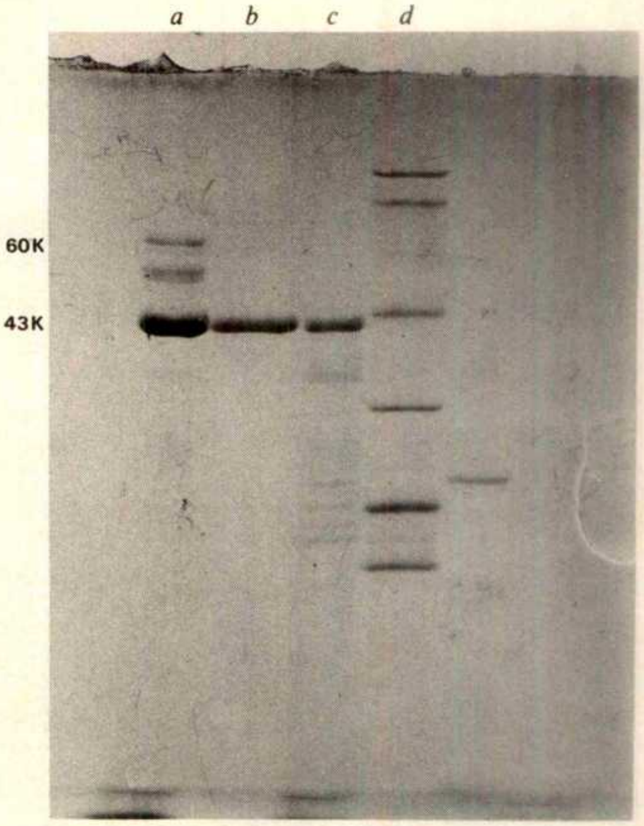

Fig. 1 Protein recovered from MITat 1.2 crystals migrates with an apparent MW of 43,000 (43K) on a 12% SDS polyacrylamide gel. *a*, 5 μg MITat 1.2 from a solution used for crystallization. The intact polypeptide migrates with an apparent MW of 60,000 (60K); the fragment at 43K corresponds to protein recovered from the crystal. *b*, Two large (0.5, 1 mm) crystals were washed in 2 ml 12% PEG, 10 mM TrisHCl, 0.1% azide, *p*H 7.5, and dissolved in a capillary with 30 μl 10 mM TrisHCl *p*H 7.5. The dissolved protein was boiled for 3 min after addition of 90 μl sample buffer; an aliquot of 20 μl was loaded on the gel. *c*, 5 μg MITat 1.2 was digested with trypsin, using the conditions of Johnson and Cross[6]; the digestion was stopped by adding excess phenylmethanesulphony fluoride and boiling after addition of sample buffer. The amino-terminal protease-resistant fragment co-migrates with the crystallized protein. *d*, Bio-Rad molecular weight standards: 92.5K, 66.2K, 45.0K, 31.0K, 21.5K and 14.5K.

A mercury derivative was obtained after a 1-day soak in a 12% PEG solution (otherwise identical to the mother liquor) saturated with K_2HgI_4. Data from one native crystal and one Hg derivative crystal were collected by diffractometer. Data were corrected for Lorentz polarization effects and radiation damage, and an empirical absorption correction was applied[10]. Friedel equivalents were scaled together in blocks of reciprocal space[11]. Data collection statistics are summarized in Table 1.

Harker sections of isomorphous and anomalous difference Pattersons showed identical peaks, and were interpretable in terms of a single Hg site at 0.20, 0.19, 0.50. After 10 cycles of refinement of the heavy-atom parameters, including the anomolous scattering data, 1,211 reflections (89% of the 15–6 Å shell) were phased with a mean figure of merit of 0.72 (Table 1). A difference Fourier showed no additional Hg sites.

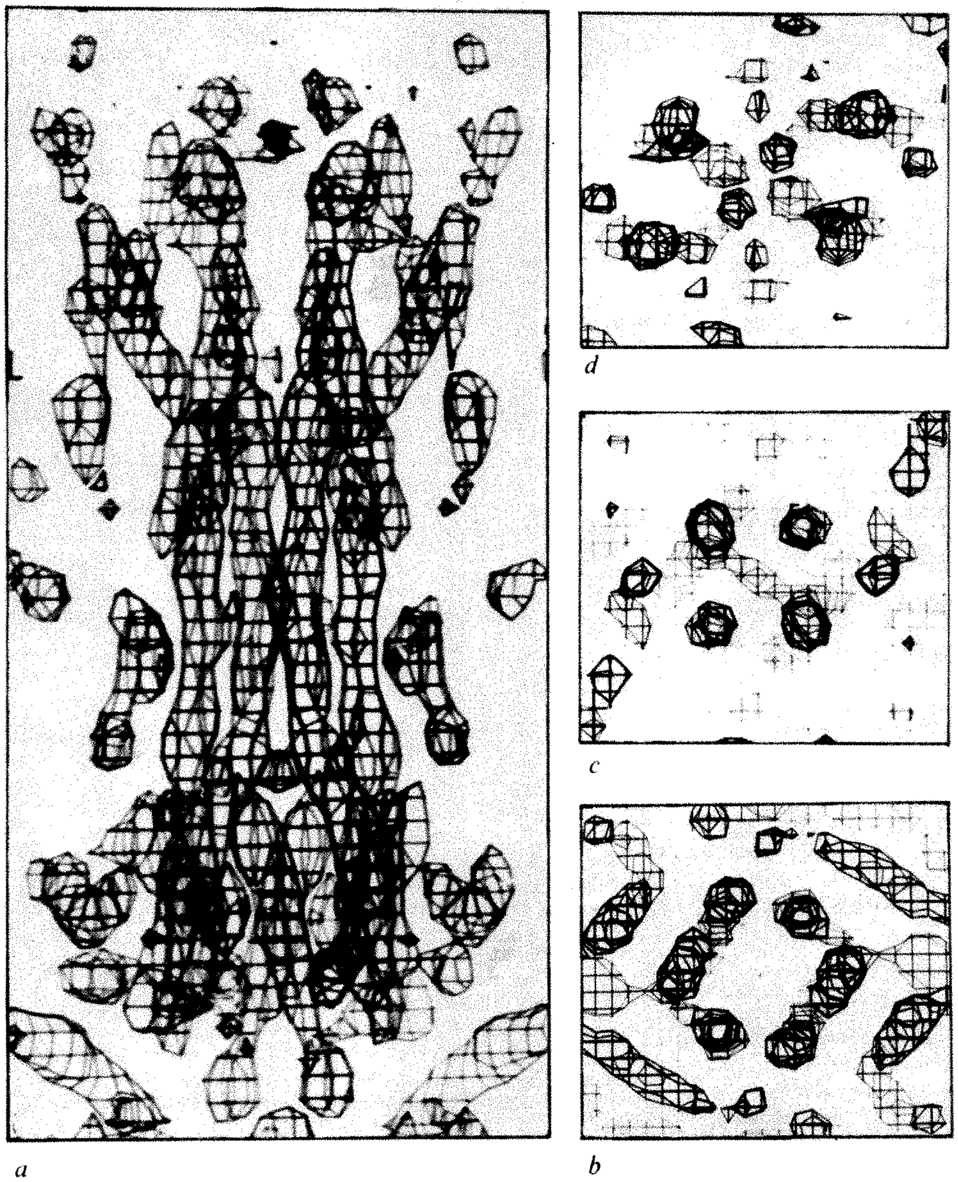

Fig. 2 *a*, View of the electron density map perpendicular to the dimer axis, which is vertical in the figure. The map was contoured two standard deviations above mean density and displayed on an Evans and Sutherland PS300 using the FRODO molecular graphics program by J. W. Pflugrath, M. A. Saper, B. Bush and A. Jones. At the bottom is the 6-fold bundle extending about 25 Å along the dimer axis. At the top, the density diverges, forming a 'two-headed' structure. (Symmetry-related density is seen in the lower corners.) *b–d*, Regions of the map shown in *a*, viewed along the dimer 2-fold axis. *b*, Approximately 20 Å from the 'bottom'. The 6-fold bundle of electron-dense rods is apparent. The distance between rods of density is ~10 Å. Unconnected density occurs adjacent to the bundle. *c*, Approximately 50 Å from the 'bottom'. The 4-fold bundle is the continuation of density which begins in *b*. *d*, Approximately 80 Å from the 'bottom'. Density from each monomer diverges and appears to form two distinct bundles.

The native electron density map calculated using the 'best' phases[12] shows that the unit cell contains four dimers packed along the crystallographic 2-fold axes. At this resolution, rods of high electron density ~10 Å apart are clearly resolved, forming a bundle which extends about 80 Å. We interpret this as an α-helical 'core' of the dimeric molecule.

The dimer is elongated, with approximate dimensions of 40×40×90 Å (Fig. 2*a*). When viewed down the dimer axis, the helical bundle is apparent (Fig. 2b–d). The connectivity of two α-helices in each monomer can be traced for about 80 Å. At one end (bottom of Fig. 2*a*) density connects the two helices, which form a 25 Å-long left-handed 6-fold bundle with another, unconnected, helical segment (Fig. 2*b*). The two helices from each subunit extend past this region to form a fairly straight four-α-helical bundle which extends about 30 Å (Fig. 2*c*). A third rod of high electron density begins adjacent to this structure. The strands then diverge to form two left-twisted structures, about 30 Å long, each of which clearly involves three helices, and possibly other adjacent density , at the 'top' of each subunit (Fig. 2*d*).

We estimate, by crude fitting of polyalanine α-helices, that about 175 residues are accounted for by the well defined helical regions of the low-resolution map. This is about 50% of the expected length of the polypeptide based on its migration on SDS-PAGE, and its consistent with circular dichroism results (M.J.T. and T. Bayley, unpublished data). We have not yet established the connectivity of additional density which occurs at the end of the dimer and around the helical bundle.

The long rod-like α-helical core of the VSG is similar, in principle, to the trimeric α-helical coiled-coil in the stem region of the influenza virus haemagglutinin (HA)[13]. The occurrence of helical motifs in other surface glycoproteins has been discussed[14]. The connectivity observed here between the two long helices in the MITat 1.2 amino-terminal domain implies a helical region extending about 120 residues with only one break. If such a structure were common to VSGs of diverse sequences, it might be revealed by analysis of secondary structure predictions. Alternatively, this feature might readily be recognized in the low-resolution structure of a second VSG. Although interesting sequence homology among VSGs has been observed in the C-terminal region[15–18], the extent of structural homology is unknown[19].

Recent work[20] has shown that the N-terminal domain of another VSG, MITat 1.6, binds most monoclonal antibodies against the intact VSG molecule; that only a subset of the monoclonal antibodies which bind to isolated intact VSG will interact with the VSG when it is in the trypanosome surface coat; and that the subset of monoclonal antibodies which bind to the trypanosome coat also bind to the N-terminal domain. These results suggest that the N-terminal domain contains the regions of the VSG which are responsible for the antigenic variation recognized by antisera against live trypanosomes. Thus

Table 1 6 Å data collection and phase refinement for MITat 1.2 VSG

	Native		Hg

Fph = derivative structure factor

$\langle Fh\rangle/\langle E\rangle$: $\dfrac{\text{r.m.s. heavy-atom structure factor}}{\text{r.m.s lack of closure error}}$

Before data collection, MITat 1.2 crystals were transferred to a solution containing 12% PEG, 10% ethylene glycol, 0.1% azide, 50 mM Tris HCl *p*H 7.5. Data were collected using a Wyckoff step scan[21] on a Syntex P3/F diffractometer equipped with a 50-cm helium-filled extension tube. About 3,000 reflections, including Friedel pairs, were collected in the 15–6 Å shell. Four reference reflections were collected every hundred reflections; the mean decay was 26% (native) and 21% (Hg) over the 3 days of data collection. The length of the *c* axis was observed to change by 1% during the data collection. Difference Patterson maps were calculated using coefficients $(Fph-Fp)$**2 and (Kemp**2/4)$(Fph^{+}-Fph^{-})$**2, where Kemp[22] was 6.43. The heavy-atom position and occupancy were refined using the program PHARE3, which alternates cycles of parameter refinement and phase calculation[23]. The anomalous scattering information was included in the refinement[24], and was used to distinguish the correct space group, $P4_12_12$, from its enantiomer[25]. B was held at 25 Å**2. The final mercury position, after 10 cycles, was $x/a=0.22$, $y/b=0.19$, $z/c=0.50$ with occupancy 0.58. The iodine atoms were not included in the refinement.

the three-dimensional structure of the N-terminal domain should contribute to establishing which parts of the sequence are implicated in the generation of antigenically distinct trypanosomes and to determining the structure of the variable epitope(s).

We thank Judith Creighton for technical assistance in the preparation of VSGs. Both laboratories have received support from the UNDP/World Bank/WHO Special Program for Research and Training in Tropical Diseases (Project No. 810278 to D.C.W. and Project No. 800328 to M.J.T.). M.J.T. also received support from ILRAD, Nairobi, Kenya).

We have used electron microscopy to examine purified intact variable surface glycoproteins (VSGs) from clones derived from two distinct stocks of *Trypanosoma brucei*. The VSG molecule from MITat 1.2 has a large elongated domain consistent with the shape of the dimeric N-terminal domain determined by X-ray analysis (see preceding paper[1]), and a heretofore unseen short, thin fibrous tail presumed to be the C-terminal domain. Electron microscopy on DiTat 1.3, however, indicates a morphology quite distinct from that of MITat 1.2. Analysis of four VSG amino acid sequences reveals 7-fold periodicities (heptad repeats) which indicate that α-helical coiled-coil secondary structure elements occur in all of these VSGs, consistent with the observation of helical bundles in one VSG[1]. These results suggest the possibility that VSG antigenic diversity may be related to a diversity in length and disposition of α-helical bundles and coiled-coil domains.

We have determined the overall morphology of certain VSG molecules in the electron microscope by rotary shadowing with platinum. The first observations were carried out on DiTat 1.3. Although the material obtained from lyophilized preparations shows considerable heterogeneity, many molecules in the field display a distinctive shape; these are ~180 Å long and consist of a globular 'head' region (~60 Å diameter) attached to a narrower 'stem' about 100 Å long and 30 Å thick that can often be seen to terminate in a small globular domain (Fig. 1). A variety of smaller fragments related to this form may also be seen (Fig. 1). SDS gels of this material indicate that most of the sample has an apparent molecular weight of 64,000 (Fig. 2). Shadowing of mixtures of VSG and tropomyosin (MW 66,000) suggests that the molecules we have observed are VSG dimers (MW 130,000). Digestion with trypsin (data not shown) indicates that the large globular head region contains the N-terminus.

We then examined intact MITat 1.2 VSG molecules whose N-terminal dimer structure has recently been solved[1]. This VSG species appears to have a markedly different morphology: particles with a major domain about 100 Å × 70 Å are observed. No clear 'stem' region is apparent, but a short tail can sometimes be seen (Fig. 3). Dissolved crystals of the dimer of the N-terminal domain show similar compact particles that lack tail regions (Fig. 3). These images agree well with the results of the X-ray structure determination, considering that particle flattening often occurs in rotary-shadowed preparations. The presence of the slender tail regions may account for difficulties in crystallizing the intact molecules[1].

Sequence information is not yet available for either of the VSG molecules that we have examined, but we have carried out conformational analyses of the published sequences of four other VSGs from the two C-terminal subsets that have been distinguished[2,3] (including VSG 117 (MITat 1.4) (ref. 4), AnTat 1.1 (ref. 5), ILTat 1.1 (ref. 6), and ILTat 1.4 (ref. 7)). Detailed findings will be reported elsewhere, but the major conclusions are summarized here. Secondary structure analyses were based on modifications of the procedures of Chou and Fasman[8], Robson and Suzuki[9] and Garnier *et al.*[10]. On this basis, some

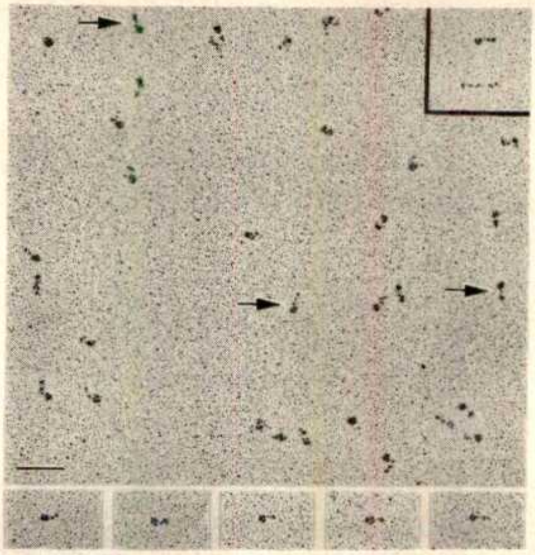

Fig. 1 Electron micrographs of rotary-shadowed VSG (*T. brucei brucei* clone T45R10, antigenic type DiTat 1.3). The molecules are ~180 Å long and show three distinct domains: a large 'globular' head region about 60 Å in diameter; a 'stem' ~100 Å long and 30 Å wide; and a smaller globular region ~40 Å in diameter. Molecules are also observed that lack the small globular region, thus appearing to have a 'tail' about 140 Å long. The field and selected molecules illustrate both types of image. Inset, a cardiac tropomyosin molecule (MW 66,000; dimensions 400 Å × 20 Å) shadowed together with VSG. The VSG molecules probably correspond to dimers. Replicas were prepared by rotary shadowing with platinum[17]. Measured dimensions may vary by ±20 Å depending on the thickness of the platinum deposit. Scale bar, 500 Å.

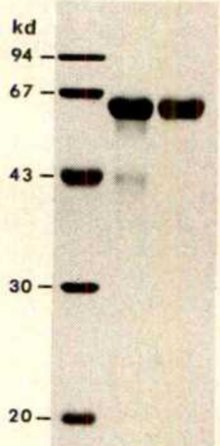

Fig. 2 Intact DiTat 1.3 monomer has an apparent molecular weight of ~64,000 by SDS-polyacrylamide gel electrophoresis. Lanes *b* and *c* show two different VSG samples, both purified from *T. brucei brucei* clone T45R10, antigenic type DiTat 1.3. The material was prepared by the method of Cross[18] and Roelants *et al.*[19] with affinity chromatography on concanavalin A–Sepharose as the final purification step, followed by lyophilization. Lane *a* shows a mixture of low-molecular weight markers (phosphorylase *b*, albumin, ovalbumin, carbonic anhydrase, trypsin inhibitor and α-lactalbumin; supplied by Pharmacia Fine Chemicals). Laemmli SDS-polyacrylamide gel (12.5%) electrophoresis.

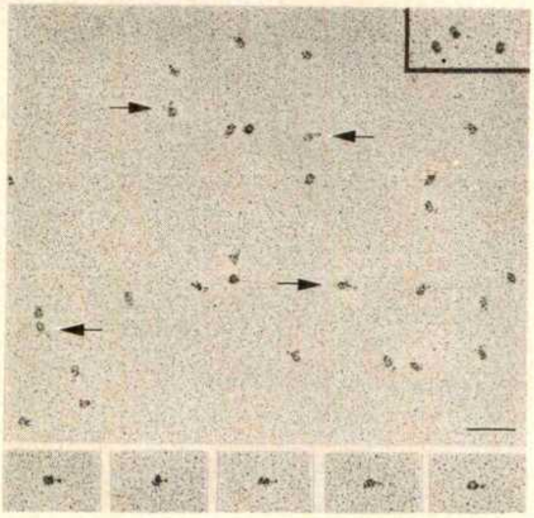

Fig. 3 Electron micrographs of rotary-shadowed VSG (*T. brucei brucei*, antigenic type MITat 1.2). The dimeric molecules display a large 'globular' domain about 110 Å × 70 Å and often a shorter (~50–100 Å) 'tail' region. Occasionally, the tail terminates in a very small globular domain. Inset, the N-terminal dimer portion of the molecule from redissolved crystals of this domain prepared as described by Freymann *et al.*[1]. Experimental details of shadowing as for Fig. 1. Scale bar, 500 Å.

50% of the VSG conformation may be α-helical. We also carried out a search for quasi-repeating heptads of the form $(a\text{-}b\text{-}c\text{-}d\text{-}e\text{-}f\text{-}g)_n$ where *a* and *d* are apolar residues[11,12] that allow an interlocking of α-helices, as envisaged by Crick, to form a coiled-coil structure[13]. Our analysis reveals that the N-terminal domains show extended 7-fold periodicity indicative of a high proportion of α-helical coiled-coil structure which differs, however, in extent and disposition between the subsets. Examples of such 7-fold repeats in two subset I VSG sequences are shown in Table 1. The extent of the regions exhibiting the heptad repeat is such that *n* commonly lies between 2 and 7, which is much less than that found for tropomyosin (where $n = 40$), but comparable to that in the rod segments of fibrinogen[11]. It should be stressed that 'broken heptads' of the type found here (with discontinuities in regularity) are compatible both with a long stretch of coiled-coil or with shorter stretches of α-helices interlocking in a more compact structure (such as a 4-α-helical motif[14]). For example, the coiled-coils could form a compact region followed by an extended stem (perhaps as in DiTat 1.3) or a more elongated bundle (as in MITat 1.2). The heptads found in the sequences have a markedly higher content of hydrophobic residues in positions *b*, *c*, *e*, *f* and *g* than those of α-helical coiled-coil muscle proteins (Table 1). This feature may be related to the characteristic dimerization of these molecules (see also 1). Although the C-terminal domains of VSG molecules may be morphologically distinct in different species (as in DiTat 1.3 and MITat 1.2), a highly charged 25-residue segment appears to be conserved in both subsets and is likely to have a membrane-binding role. Our results on α-helix content are in general agreement with the recent study of Lalor *et al.*[15]; we believe, however, that consideration of the heptad regularity is a critical aspect of the sequence analysis and one which has important structural and functional implications.

At present only parts of the puzzle are available to establish strict morphology/sequence/function relations in the VSGs. Nevertheless, our results, taken together with the recent X-ray crystallographic studies of Freymann *et al.*[1], suggest some design principles for these surface glycoproteins. As described by Cohen and Phillips[16], the α-helical coiled-coil is a fundamental feature of the structure. The length and disposition of α-helices in the exposed N-terminal variable region may differ, however, in different species of VSG (see also ref. 15). It is also possible that the broken heptad repeats in the sequences provide a device for generating structural diversity. Thus, the α-helical segments

	Ala	Met	Tyr	Ser	Ser	Gly	Arg
	Ile	Asp	Glu	Leu	Met	Leu	Leu
	Leu	Glu	(Gly	His	Arg	Glu	Asp
	Gly	Ala	Asn	Gly	Gln	Asp	Lys Thr Cys)

Apolar residues in positions *a* and *d* permit the adoption of a coiled-coil structure. Residues in parentheses introduce a discontinuity in the heptad repeat, represented by a space in the sequence. The upper sequence is from VSG 117 (MITat 1.4) between Cys 14 and Cys 121. The lower sequence is from AnTat 1.1 between Cys 45 and Cys 154. The sequences of AnTat 1.10 and 1.1B give similar results. Subset II VSGs appear to be somewhat different: broken heptad runs occur farther along in the sequence—for example, between residues 237 and 339 in ILTat 1.1 and 151 and 277 in ILTat 1.4.

may adopt a variety of closely related forms, from extended to compact, that depend as well on the constraints imposed by disulphide bridges. Such a range of possible conformations (unlikely for α-helical regions lacking heptad repeats) may have implications for the antigenic variability of these proteins. Although the antigenic diversity may arise from amino acid replacements *per se*, it could also depend on structural changes, possibly gross, controlled by broken heptad repeats that can result from a small change of sequence.

Mutant viral RNAs synthesized *in vitro* show altered aminoacylation and replicase template activities

T. W. Dreher*, J. J. Bujarski & T. C. Hall*

Biophysics Laboratory of the Graduate School, University of Wisconsin-Madison, Madison, Wisconsin 53706, USA

A remarkable feature of the genomic RNAs of several plant viruses is the presence at the 3′ end of a region that exhibits tRNA-like functions, including aminoacylation[1–3]. The three genomic and single subgenomic RNAs of brome mosaic virus (BMV) accept tyrosine *in vitro*[4] and *in vivo*[5], the smallest 3′ fragment that can be aminoacylated being about 135 nucleotides long[6]. The roles of the tRNA-like properties are incompletely understood, but an involvement in replication rather than translational functions is likely[3,7,8]. We have recently shown (J.J.B. *et al.*, in preparation) that the features recognized by the BMV RNA-specific RNA-dependent RNA polymerase (replicase)[9,10] for the use of BMV RNA for complementary strand synthesis also lie within the tRNA-like structure. To distinguish between the roles of BMV RNA as a substrate for tyrosyl-tRNA synthetase and BMV replicase, we have now produced BMV RNAs with mutations at two separate loci within the tRNA-like structure. This has been achieved by transcription *in vitro* from specifically mutagenized cDNA, an approach permitting the generation of targeted mutants without regard to their viability *in vivo*.

The synthesis of RNAs active in aminoacylation, a function known to be stringently dependent on a correct 3′-CCA terminus[11,12], required the extension of existing *in vitro* transcription techniques[13,14]. Correct 3′ termini were obtained by transcription from a template linearized at a position corresponding to the 3′ end of the BMV cDNA sequence; a *Tth*111I restriction site was created at such a location within a 201-base pair (bp) BMV RNA3 cDNA clone containing the tRNA-like structure (Fig. 1*a*). After placing the BMV sequence under the control of an SP6 promoter[13,15] (Fig. 1*b*), microgram quantities of BMV RNA transcript of the expected size (207 nucleotides) were prepared from *Tth*111I-linearized template DNA. The transcribed RNA was active in two assays characteristic of the tRNA-like structure of BMV RNA: aminoacylation and complementary strand synthesis by BMV replicase. The behaviour of BMV RNA transcripts in both assays was comparable to that of native virion RNA. These activities are discussed below in comparison with those of mutated RNAs.

Point mutations were introduced into the BMV cDNA segment of clone mpTD11 by oligonucleotide-directed mutagenesis[16]. Mixed oligonucleotide primers[17], containing sequence ambiguities at two adjacent bases, were used to construct libraries expected to contain all possible single and double base mutants for each dinucleotide target. This procedure was applied to two loci in the BMV sequence, the 3′ end and the –AUA–tyrosyl anticodon triplet. Figure 2*a* identifies the sequence substitutions of BMV RNAs produced from clones selected from mutant libraries.

---

* Present address: Department of Biology, Texas A & M University, College Station, Texas 77843, USA.

Transcripts representing the wild-type and mutant BMV RNAs (207 nucleotides) migrated identically during electrophoresis (Fig. 2*b*). Termination of transcription did, however, show some heterogeneity, as indicated by the poorly resolved doublets. The 3′ termini of all transcripts studied here were analysed by 3′-terminal labelling with 5′-^{32}P-pCp (ref. 18), followed by complete digestion with alkali or specific ribonucleases (data not shown). Although transcriptional termination on such linear templates gave rise to a limited range of products, it was clear that the heterogeneity existed beyond the required 3′ end, that no significant premature termination was caused by the end of the DNA template, and that about one-third of transcript molecules consistently contained the expected 3′ end. The run-off transcription system described here is thus capable of producing faithfully terminated RNA molecules.

Wild-type transcripts were aminoacylated with kinetics similar to those of virion RNA; about 40% of transcribed molecules were tyrosylated (Fig. 3*a*). This is consistent with an estimated one-third of transcribed molecules having a correct 3′ terminus (see above). All five mutants in which the anticodon was changed to that of three different amino acids, or to the amber nonsense triplet, were as active in tyrosylation assays as were wild-type transcripts, and displayed indistinguishable kinetics (Fig. 3*a*). In contrast, all four mutations at the 3′ terminus abolished aminoacylation. The low level of tyrosylation observed after longer incubations with mutant RNAs containing single base changes at the far 3′ end was due to turnover of the 3′ nucleotide[12], which generated some molecules with a correct −CCA end. tRNA nucleotidyl transferase and low levels of nuclease are known to be present in the partially purified synthetase preparations used.

The above sets of RNAs were assayed for their abilities to act as templates for BMV replicase (Fig. 3*b*). Wild-type transcripts showed similar activity to BMV RNA4, yielding full-length, double-stranded RNA. All of the point mutations studied

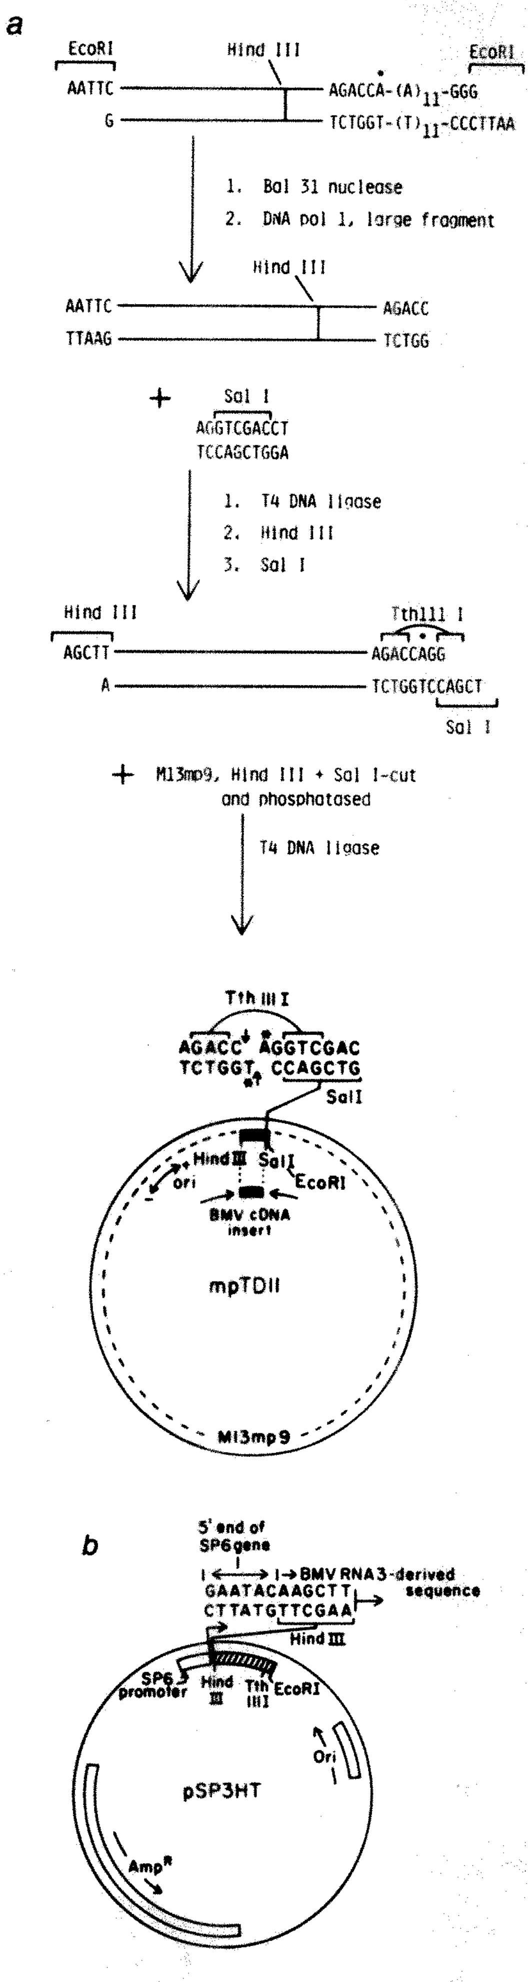

Fig. 1 Construction of a plasmid allowing the synthesis by transcription of RNA molecules comprising the tRNA-like region of BMV RNA3 and terminating in correct 3′ ends. *a*, Scheme for the creation of a *Tth*111I site with the cleavage position coincident with the 3′ end of the BMV RNA3 cDNA sequence. Clone mpTD11 contains the cDNA sequence corresponding to the 201 3′ nucleotides of BMV RNA3. *Marks the 3′ end of the BMV cDNA sequence. The cleavage positions for the *Tth*111I restriction endonuclease are indicated by arrows. *b*, Diagram of the transcriptional plasmid pSP3HT, obtained by subcloning the *Hin*dIII to *Eco*RI insert of mpTD11 (cross-hatched) into plasmid pSP64, a pUC12 (refs 25, 26) derivative containing an SP6 promoter fragment, and constructed in the laboratory of D. Melton. The 5′ region of the DNA sequence transcribed by the SP6 RNA polymerase is shown; transcripts possess six bases at their 5′ ends originating from the SP6 gene.

Methods: A fragment comprising the cDNA sequence corresponding to BMV RNA3 was released by *Eco*RI cleavage of 10 μg of a plasmid supplied by P. Ahlquist. To remove the poly(dA) tail added during cDNA cloning, the DNA mixture was treated with *Bal*31 nuclease (0.6 units, BRL) at 16 °C in a reaction containing 20 mM Tris-HCl (*p*H 8.1), 0.6 M NaCl, 12 mM $CaCl_2$, 12 mM $MgCl_2$, 1 mM EDTA and 250 μg ml^{-1} bovine serum albumin (BSA)[27]. Portions of the reaction, taken at 7, 10 and 13 min, were pooled and the reaction was stopped in 20 mM EGTA, phenol extracted and ethanol precipitated. Treatment with *Escherichia coli* DNA polymerase I (large fragment, BRL)[28] was used to increase the proportion of fragments with blunt ends before linker addition. A decameric self-complementary oligodeoxynucleotide d(AGGTCGACCT), which contained an internal *Sal*I site and was capable of creating a *Tth*111I site when ligated to the desired *Bal*31-deleted DNA, was synthesized by the phosphite triester procedure[29] using a DNA Synthesis Kit from New England Biolabs. The oligomer (0.6 μg) was phosphorylated to completion using T4 polynucleotide kinase (Pharmacia-P/L) in a reaction containing 200 μCi[γ-^{32}P]ATP (3,000 Ci mmol^{-1}; Amersham) chased with 500 μM unlabelled ATP[30]. After ligation of the ^{32}P-labelled decameric linker to the *Bal*31-treated DNA, the DNA was digested with *Hin*dIII (BRL) and linkers were depolymerized by complete digestion with *Sal*I (Pharmacia-P/L). Digestion products were electrophoresed through a 1.5% low melting point agarose gel, and a band (~200 bp) was extracted. The DNA was ligated to *Hin*dIII + *Sal*I-digested, phosphatased M13mp9 vector[26] using T4 DNA ligase. Following transfection into *E. coli* JM101, clone mpTD11 (shown) was isolated by screening plaques for the presence of a *Tth*111I restriction site in replicative form DNA.

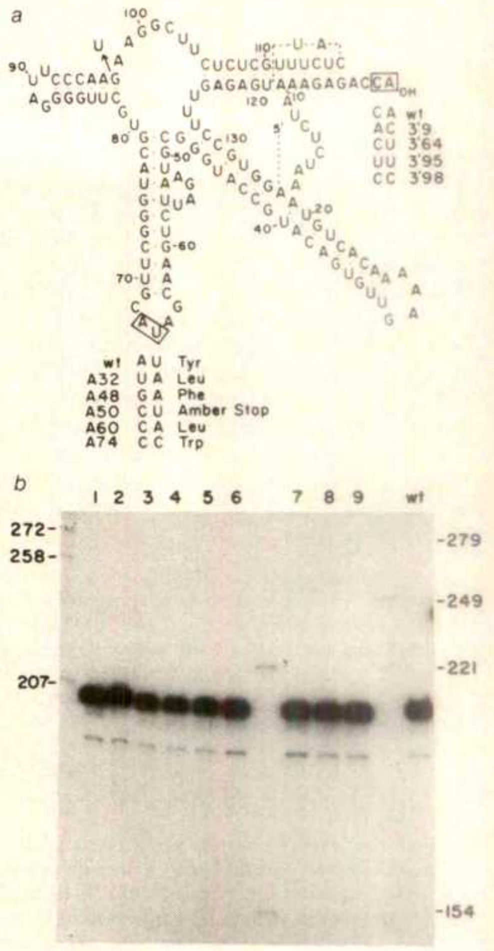

Fig. 2 Synthesis of BMV RNAs with mutations within the tRNA-like structure. ***a***, Two-dimensional representation of the postulated conformation of the tRNA-like structure of BMV RNA3 (after Rietveld *et al.*[31]). Nucleotide positions are numbered from the 3′ end, and the two pairs of adjacent nucleotides at which mutations have been introduced are boxed: the 3′ terminus and the putative anticodon. Mutant clones were sequenced both before and after subcloning into the transcriptional plasmids, and the sequences of their transcripts are indicated for each locus; the amino acid corresponding to each anticodon triplet is also shown. The wild-type transcripts studied here varied from the RNA consensus sequence shown by the single base change G97 to U97 (indicated), which was also present in mutant transcripts. This substitution appeared neutral with respect to aminoacylation and BMV replicase template activity. Note that the split recognition sequence of *Tth*111I GACN′NNGTC permits 3′ mutations. ***b***, Analysis of transcripts arising from mutated BMV cDNA clones on a 5% polyacrylamide-7 M urea sequencing gel. The migrations of DNA markers are indicated. Lanes 1–9, mutant transcripts 3′9, 3′64, 3′95, 3′98, A32, A48, A50, A60 and A74 respectively; wt is the wild-type transcript. Transcripts labelled with [α-^{32}P]UTP were synthesized from *Tth*111I-linearized transcriptional plasmids using SP6 RNA polymerase[13].

Methods: Construction of mutant clones: Libraries of all possible double and single mutants at each locus were generated in a single mutagenizing experiment from single-stranded phage DNA (clone mpTD11), by an extension of published methods[16,17]. 3′-Terminal mutations: A hexadecameric deoxyoligonucleotide mixture of sequence d(GTCGACCXYGTCTCTT) was synthesized as above. The positions designated X and Y were the sites directing the mutagenesis, where X = dT and Y = dG in the wild-type sequence. During synthesis, the condensation reaction at position Y contained a molar ratio of 3dC:3dA:3dT:dG of the protected nucleotide reagents. At position X, the molar ratios were 3dC:3dA:3dG:dT. In this synthesis system, molar ratios of condensation products are roughly proportional to the concentration of reagents in the reaction. The low proportion of the wild-type nucleotide was used to depress the ratio of recreated wild-type clones after mutagenesis. Conditions expected to allow priming of second strand synthesis by oligomers with double and single mismatches were established in pilot dideoxy sequencing reactions with the synthetic hexadecameric mixture as primer. The oligomer mixture was kinased and mixed with 1.5 μg of single-stranded mpTD11 template (~15-fold molar excess of primer) in 9 μl containing 20 mM Tris-HCl (*p*H 7.5), 10 mM $MgCl_2$, 50 mM NaCl and 1 μM dithiothreitol. After boiling for 2 min, the mixture was annealed at 37 °C for 15 min, chilled on ice and brought to room temperature just before second strand synthesis. The reaction proceeded as recommended[16]. 100 phage clones were screened by temperature-shift hybridization, in which M13 phage was applied directly onto nitrocellulose (Schleicher & Schuell) and the [γ-^{32}P]-labelled synthetic oligomer mixture was used as probe[16,17]. Hybridization was carried out at room temperature overnight, and was followed by 5-min washes at successively higher temperatures (37, 45, 55 and 60 °C), alternating with exposure of the dot blots to film. Suspected mutant phage were analysed by dideoxy sequencing[32] using the M13 universal primer (17mer, New England Biolabs). Some phage selected on the basis of hybridization results did prove to be wild type. Because the blotted phage were not screened exhaustively, the proportion of mutants achieved was not determined. Anticodon mutations: The 21mer oligomer mixture used for mutagenesis at this locus was synthesized as above. The sequence was d(GACTTGCTWZGCAAGCCCATG), where W = dA and Z = dT in the wild-type sequence. The molar ratios at position W were 3dG:3dC:3dT:dA and at position Z were 3dG:3dC:3dA:dT. Mutagenesis was performed as above, except that the annealing temperature was 50 °C. During screening, washes were for 5 min at 50, 57, 67 and 72 °C. At least 8% of phage were mutants. Mutant clones were plaque purified, and the *Hin*dIII–*Eco*RI insert was subcloned into pSP64 as for the wild-type clone (see Fig. 1).

Table 1 Relative activities of mutant transcripts as templates for BMV replicase and in aminoacylation

Transcript	Relative replicase template activity	Relative aminoacylation activity
wt	1.00	1.00
3′9	0.05	0.00
3′64	0.34	0.02
3′95	0.05	0.01
3′98	0.32	0.01
A32	0.15	1.00
A48	0.15	0.97
A50	0.20	0.82
A60	0.18	0.94
A74	0.14	0.99

Replicase template activities were estimated by determining the ratio of ^{32}P c.p.m. incorporated into product by BMV replicase to ^{3}H c.p.m., a measure of the amount of synthetic template (transcript) present. Replicase reaction products were phenol extracted and electrophoresed through 5% sequencing gels, conditions in which product and template co-migrate. Bands located by exposure to film were excised from the gel, and the RNA present was base hydrolysed using Soluene 100 (Packard), and analysed in a liquid scintillation spectrometer for ^{32}P and ^{3}H c.p.m. Aminoacylation activities were derived from the amounts of ^{3}H-tyrosine bound after 5-min incubations (Fig. 3*a*). This avoids the confusion with the end-group repair which occurs for transcripts 3′64 and 3′98 during longer incubations. Aminoacylation differences between anticodon mutants were not significant. wt, Wild type.

within the anticodon uniformly and markedly inhibited the template activity of the RNA. The template activity of 3′ end mutants was governed by the location of the substitution. Transcripts with mutations only at the terminal position were active templates, although their activity was about one-third that of the wild-type transcript. In contrast, transcripts with substitutions at both the penultimate and terminal positions were very poor templates. The lowered activity of 3′ mutant RNAs probably results from interference with the normal initiation of RNA synthesis.

The relative aminoacylation and replicase template activities of wild-type and mutant transcripts are compared in Table 1. Aminoacylation results were derived from charging levels after 5-min incubations, at which time 3′ nucleotide turnover is undetectable (Fig. 3*a*). Replication activities were quantified by determining the ratio of product to template RNA in replicase reactions. Mutations at each locus had differential effects on the two activities. Several mutations within the anticodon triplet show that BMV replicase, and not tyrosyl-tRNA synthetase, interacts with this sequence, which exists in an exposed loop of the tRNA-like structure. The anticodon residues may thus be involved in the specific recognition of BMV RNA by the replicase.

The indifference of tyrosyl-tRNA synthetase to mutations in the anticodon of BMV RNA requires comment. Chemical modifications and mutations of the anticodons of tRNAs have not inhibited aminoacylation in all systems studied (compare refs 19, 20). Further, although anticodons corresponding to the specifically bound amino acid are present in several plant viral RNAs[2,3], their occurrence is not universal; some viruses closely related to BMV, and whose RNAs bind tyrosine[21], do not have analogous anticodons[6,22,23]. This variation is compatible with the anticodon residues representing important determinants of replicase specificity. However, such observations leave open the question of the significance of the correspondence between bound amino acid and anticodon in RNAs from viruses such as BMV.

Four different mutations at the 3′ terminus of BMV RNA abolished tyrosine-accepting activity. Thus, the −CCA terminus is as necessary for the aminoacylation of BMV RNAs as it is for tRNAs[1,12]. In contrast, BMV replicase is not as stringent in its requirement for a correct 3′ terminus, and mutants with substitutions in the terminal position retained 33% of replicase template activity. However, substitutions at both of the 3′-terminal positions resulted in 95% loss of activity. These results are consistent with initiation of (−)strand synthesis very close to the 3′ end (J.J.B. *et al.*, in preparation), possibly at the penultimate C residue.

The approach described here for rapidly obtaining mutant RNA molecules with defined 3′ termini is likely to be useful for studying the functions of various RNA molecules, including tRNAs, especially when the desired mutations cannot be obtained by traditional means or when the mutations are likely to be lethal. This system offers clear advantages over an RNA synthesizing system based on Qβ replicase[24], which requires substantial Qβ sequences at the 3′ end of the RNA. Placement of cloned DNA sequences immediately adjacent to the SP6 promoter will permit the synthesis of RNAs with both authentic 5′ and 3′ ends.

We thank Dr M. Wickens for supplying SP6 RNA polymerase before its commercial availability, and for helpful discussions. Dr D. Melton supplied the transcriptional plasmid pSP64 and Dr P. Ahlquist supplied the BMV cDNA clone used. We thank Allen Miller for discussions, Dr L. A. Ball for help with the manuscript, Chris Harkin for technical assistance, and Professor

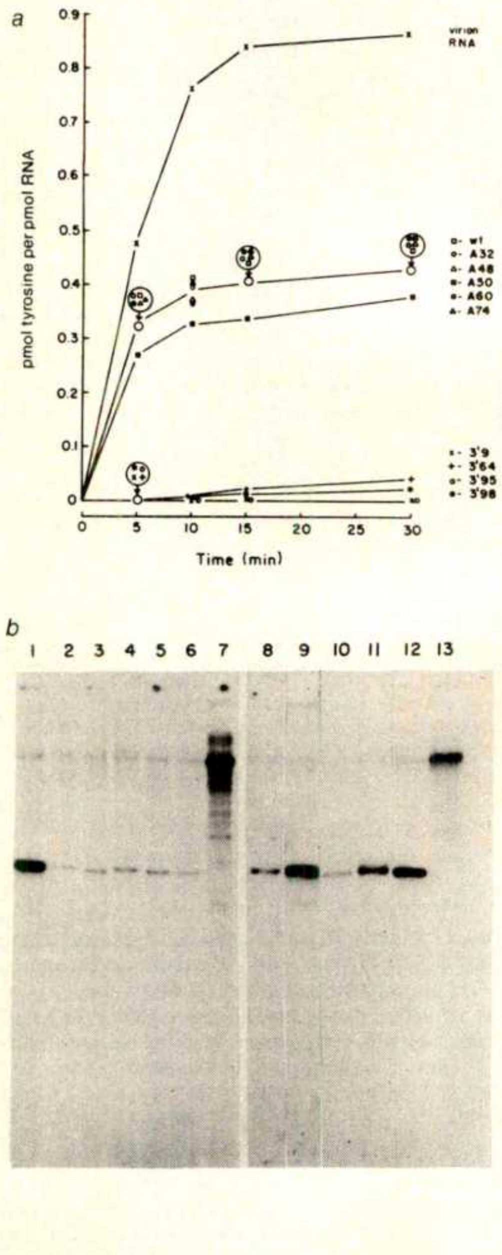

Fig. 3 Biological activity of wild-type and mutant BMV RNAs synthesized *in vitro*. *a*, Aminoacylation of transcripts. *b*, Activity of transcripts as templates for BMV replicase. Lanes 1 and 12, replicase reaction product with wild-type transcript as template; lanes 2–6, products with anticodon mutant transcripts as templates, A32, A48, A50, A60, A74 respectively; lanes 8–11, products with 3′ mutant transcripts as templates, 3′9, 3′64, 3′95, 3′98 respectively. Lanes 7 and 13 are products obtained using 1.2 μg BMV RNA4 as template; low levels of products synthesized from endogenous RNA4 are evident in the other lanes, and are useful internal controls.

Methods: *a*, BMV RNA was prepared as previously reported[21]. Transcripts were labelled to a known specific activity of ~60,000 d.p.m. per μg with [α-^{32}P]UTP (Amersham), allowing calculation of the amount of RNA used in each aminoacylation reaction. Reactions (50 μl) containing 3 μg of *Tth*111I-linearized DNA, 3.5 units of SP6 RNA polymerase and 500 μM each nucleotide triphosphate typically yielded 3–5 μg of transcribed RNA. RNA was phenol extracted and purified either using DEAE-Sephacel (Pharmacia) followed by ethanol precipitation, or by two successive ethanol precipitations in the presence of ammonium acetate. In both cases unincorporated nucleotides were completely removed. Because template DNA was shown not to interfere with the aminoacylation assay, it was not removed. Aminoacylation (tyrosylation) assays used a partially purified preparation of aminoacyl-tRNA synthetases from wheat germ[33]. Reactions (50 μl) contained 0.5–0.7 μg of ^{32}P-labelled transcript RNA, 7.3 μCi ^{3}H-tyrosine (54.6 Ci mmol^{-1}; NEN), 48 mM KCl, 5 mM MgCl$_2$, 0.64 mM ATP and 5 μl of synthetase preparation and were incubated at 30 °C. Aliquots were taken at the times indicated, and incorporation of ^{3}H-tyrosine was determined by precipitation of RNAs onto filter paper with trichloroacetic acid. Radioactivity was counted in a liquid scintillation spectrometer in conditions suitable for ^{32}P/^{3}H double counting. The results shown are averages from two experiments for virion RNA, and of duplicate assays on at least two independently synthesized sets of transcripts. The altered sequences for mutant transcripts are identified in Fig. 2*a*. The results for transcript A50 were not significantly different from those of wild type or other anticodon mutants. *b*, Template activities of mutant and wild-type transcripts were assayed by incubation with BMV replicase, prepared from BMV-infected barley leaves and treated with micrococcal nuclease[9,10]. Labelled complementary strand was synthesized in 25 μl reactions containing 1 μM [α-^{32}P]UTP (80 Ci mmol^{-1}; Amersham), 80 μg ml^{-1} actinomycin D, 20 μl of BMV replicase preparation and template RNA. The reaction mixture was incubated at 30 °C for 30 min, extracted twice with phenol–chloroform, ether extracted and ethanol precipitated in the presence of ammonium acetate. A portion of the replicase reaction products was treated with ribonuclease[9] before electrophoresis to confirm the presence of double-stranded products (not shown). Transcripts were prepared as above, but were labelled with [α-^{3}H]UTP (NEN) to a specific activity of about 3×10^5 d.p.m. per μg. Replicase reaction products with mutant and wild-type BMV transcripts and virion BMV RNA4 as templates were run on a 5% nondenaturing polyacrylamide gel and autoradiographed. Replicase reactions contained 0.9 μg of transcript for 3′9 and 3′64 (lanes 8, 9), and 0.3 μg for all others.

The plasma protease inhibitors control a wide variety of physiological functions including blood coagulation, complement activation and aspects of the inflammatory response. The inhibitors function by forming a 1:1 complex with a specific protease within the reactive centre region of the inhibitor. Little is known about the evolutionary relationships of these inhibitors. We report here the sequences of cDNAs which represent the C-terminal halves of the two major murine plasma protease inhibitors. One of these, murine α_1-antitrypsin, more appropriately called α_1-proteinase inhibitor (α_1-PI), has diverged from its human counterpart at a vital position in the reactive centre but this has not led to a physiologically significant change in function. Also, we have determined the partial sequence of a recently characterized protein termed contrapsin, which inhibits trypsin-like proteases[1,2]. We show, surprisingly, that contrapsin is highly homologous to human α_1-antichymotrypsin, an inhibitor of chymotrypsin-like proteases. The reactive centre regions of these two inhibitors have diverged considerably, which may account for the differences in specificity. We propose that the genes for contrapsin and human α_1-antichymotrypsin are the descendents of a single gene that have evolved since rodent and primate divergence to encode proteins with different functions.

Previously, we have isolated cDNA clones corresponding to abundant liver-specific mRNA sequences[3]. Two of these clones, p1796 and p54, are complementary to mRNA encoding, respectively, the protease inhibitors α_1-PI and contrapsin (our unpublished data and Jack Gauldie, personal communication). Figure 1 shows the DNA sequence analysis of the p1796 and p54 inserts. The two cDNA inserts are approximately 800 nucleotides long, representing the 3′ half of the corresponding mRNA. Figure 1*a* compares the nucleotide and derived amino acid sequences of murine α_1-PI with those published for the primate α_1-PI (ref. 4). Over the region analysed, the mouse sequence is 70% homologous with the primate α_1-PI at the nucleotide level, and 60% at the amino acid level. This degree of evolutionary divergence is common among many of the serum proteins studied[5,6].

Comparison of the sequence of mouse contrapsin (Fig. 1*b*) with that of murine α_1-PI (Fig. 1*a*) reveals that the two inhibitors are related, sharing 59% homology at the nucleotide level and 44% at the amino acid level. This suggests that the two proteins diverged from a common ancestral gene probably some 200–300 Myr ago.

Contrapsin is a major component of the protease inhibitory activity of mouse plasma; however, this activity is not detected in human plasma[1]. To search for a possible human counterpart, we screened a human liver cDNA library for complementary sequences[7]; approximately 0.1% of the clones screened gave a strong positive signal with the mouse contrapsin insert. One representative clone, pHL6.1, was selected and the region corresponding to the mouse cDNA insert sequenced. Figure 1*b* compares the mouse and human sequences, which are 70% homologous at the nucleotide level and 60% homologous at the amino acid level—the same degree of homology that murine α_1-PI shares with its human counterpart. Analysis of the human sequence shows that it is identical to the published sequence of human α_1-antichymotrypsin[8,9] except for two amino acid differences. One of the amino acid differences places the termination codon 32 nucleotides upstream of the published triplet due to the addition of an A at nucleotide position 659. Therefore, murine contrapsin and human α_1-antichymotrypsin are highly homologous.

Recently, a protease inhibitor 'superfamily' has been described which includes the human serine protease inhibitors α_1-PI (ref. 10), antithrombin III (ref. 11) and α_1-antichymotrypsin[9] and two proteins having no reported inhibitor activities—chicken ovalbumin[12] and rat angiotensinogen[13]. We would now include mouse contrapsin in this 'superfamily'. We have aligned the sequences of all the members of this superfamily with our sequences and find that they have 15 amino acids in common. It is of interest that in all the members, except angiotensinogen, there is conservation of the two glutamic acid residues designated by arrows in Fig. 1*a*. Angiotensinogen contains only the first of the two residues. Two well characterized mutations[14–17] that occur in human α_1-PI, the S and Z polymorphisms which lead to low serum levels of the protein, result from substitutions at these sites. Conservation of these two amino acids suggests that these residues have an important role in the stabilization and secretion of this family of proteins.

Protease inhibitors are traditionally described according to their reactivity to proteases *in vitro* and the specificity of the inhibitor is determined by the reactive centre region of the protein. *In vitro* the protease may specifically cleave within the reactive centre between two amino acids at positions designated P_1 and P_1'. Studies involving substitution of different amino acids within the reactive centre suggest that the residue at the P_1 position is consistently the most important in determining the specificity of the inhibitor[18]; this was substantiated by a naturally occurring mutation in α_1-PI called α-PI Pittsburgh, in which a single amino acid change at the P_1 position produced a protein having no α_1-PI activity but possessing a several thousand-fold increase in antithrombin activity[19] (Fig. 2).

The reactive centre regions of human α_1-PI and α_1-antichymotrypsin are located towards the C-termini of the proteins. Alignment of the mouse inhibitor sequences with the related

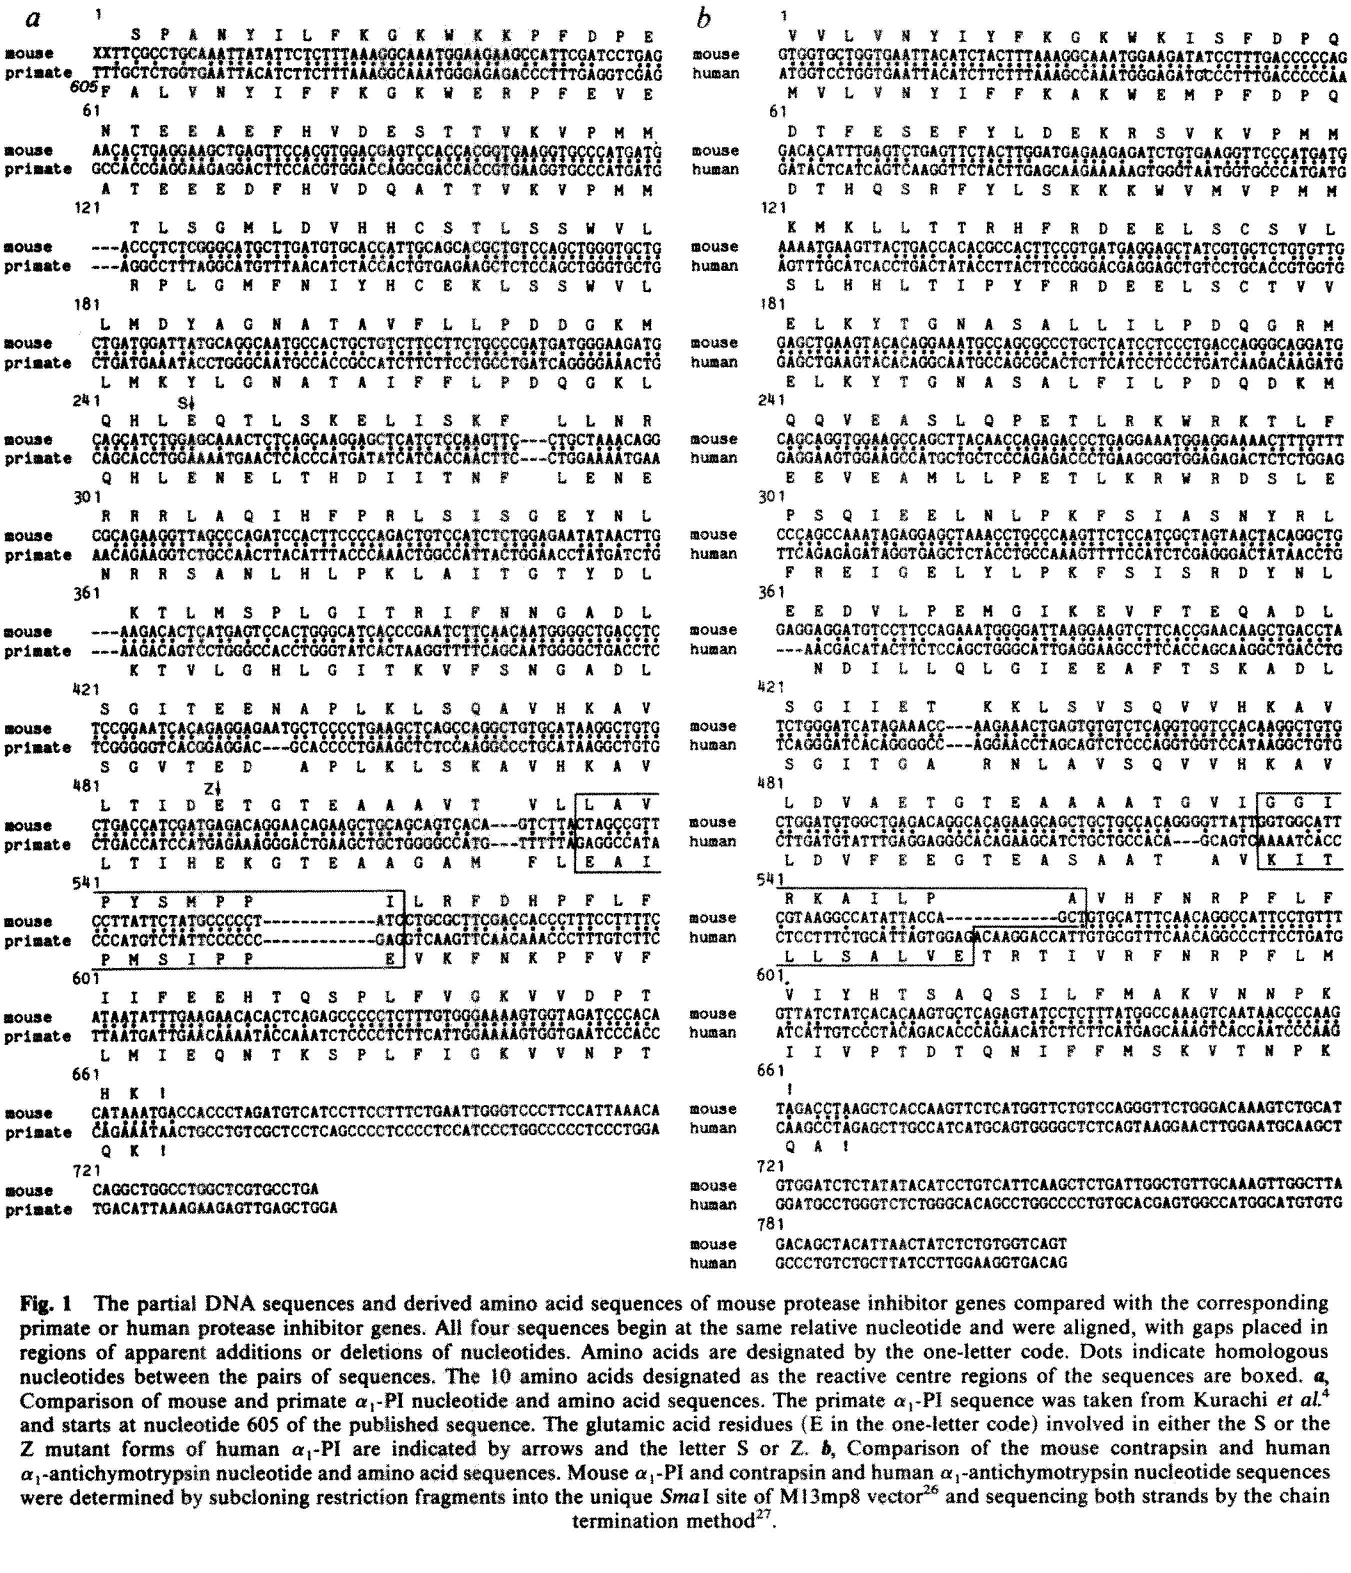

Fig. 1 The partial DNA sequences and derived amino acid sequences of mouse protease inhibitor genes compared with the corresponding primate or human protease inhibitor genes. All four sequences begin at the same relative nucleotide and were aligned, with gaps placed in regions of apparent additions or deletions of nucleotides. Amino acids are designated by the one-letter code. Dots indicate homologous nucleotides between the pairs of sequences. The 10 amino acids designated as the reactive centre regions of the sequences are boxed. *a*, Comparison of mouse and primate α_1-PI nucleotide and amino acid sequences. The primate α_1-PI sequence was taken from Kurachi *et al.*[4] and starts at nucleotide 605 of the published sequence. The glutamic acid residues (E in the one-letter code) involved in either the S or the Z mutant forms of human α_1-PI are indicated by arrows and the letter S or Z. *b*, Comparison of the mouse contrapsin and human α_1-antichymotrypsin nucleotide and amino acid sequences. Mouse α_1-PI and contrapsin and human α_1-antichymotrypsin nucleotide sequences were determined by subcloning restriction fragments into the unique *Sma*I site of M13mp8 vector[26] and sequencing both strands by the chain termination method[27].

human sequences allowed us to predict the positions of the reactive centre regions in the mouse inhibitor (Fig. 1). The reactive centre regions of the human and mouse α_1-PI differ by several amino acids (Fig. 2), most importantly, perhaps, at the P_1 position which in the human is a methionine and in the mouse a tyrosine. A major function of the human α_1-PI is the inhibition of neutrophil-secreted elastase[20,21]. Similarly, murine α_1-PI is a potent inhibitor of mouse elastase ($K_i = 2.1 \times 10^{-11}$)[2], suggesting that the physiological specificity of these inhibitors is the same. However, the specificity of the murine α_1-PI against some proteases *in vitro* differs from that of the human inhibitor. In this case, the difference at the P_1 position may affect the inhibitory properties of these two proteins *in vitro* but is probably of no physiological consequence.

In contrast, mouse contrapsin and human α_1-antichymotrypsin differ greatly in their specificities; that is, contrapsin is active against trypsin-like proteases[1,2] and α_1-antichymotrypsin inhibits chymotrypsin-like proteases[20,22,23]. Consistent with this, the reactive centre regions of these sequences differ substantially. Over the stretch of 10 amino acids that encompasses the reactive centre, one amino acid is shared (Fig. 2), with only 30% homology at the nucleotide level (Fig. 1*b*), whereas the nucleotide homology surrounding this region is strikingly high. At the P_1–P_1' position, the mouse inhibitor contains Lys-Ala residues in contrast to the human Leu-Ser residues. It has been predicted that an inhibitor with a lysine residue at the P_1 position would be more effective against trypsin-like proteases[24] than chymotrypsin-like proteases. The P_1' position

Protease inhibitor	P_5	P_4	P_3	P_2	P_1	P_1'	P_2'	P_3'	P_4'	P_5'
mouse contrapsin	GLY	GLY	ILE	ARG	LYS /	ALA	ILE	LEU	PRO	ALA

α_1-PI Pittsburgh					(ARG)					
human ATIII	VAL	ILE	ALA	GLY	ARG /	SER	LEU	ASN	PRO	ASN
BPTI	THR	GLY	PRO	CYS	LYS /	ALA	ARG	ILE	ILE	ARG

Fig. 2 Comparison of the reactive centre regions of several protease inhibitors. α_1-PI Pittsburgh[18], a mutant form of human α_1-PI differing by one amino acid situated at the P_1 site and which has acquired antithrombin activity, is compared with human antithrombin III (ATIII)[9-11] which has the same amino acid at the P_1 site as α_1-PI Pittsburgh. Bovine pancreatic trypsin inhibitor (BPTI)[25,28] is an example of a protein with trypsin inhibitory activity having a P_1–P_1' site identical to that of mouse contrapsin. α_1-achy, α_1-antichymotrypsin.

is of interest here as the mouse protein is the only member of this family of inhibitors that does not have a serine at this position[18]; the functional significance of this is not known. However, a protein (bovine pancreatic trypsin inhibitor) (Fig. 2) from an unrelated family of protease inhibitors also has Lys-Ala at the P_1–P_1' position and, as predicted, exhibits antitrypsin activity[24,25]. We propose, therefore, that mouse contrapsin is closely related to human α_1-antichymotrypsin but has different inhibitory activity due to divergence within this short, functionally important stretch of amino acid residues.

In man, α_1-PI and α_1-antichymotrypsin are two of the most abundant serum protease inhibitors. In the mouse, the two most prevalent inhibitors are α_1-PI and contrapsin. Attempts to demonstrate a contrapsin-like protein in man[1,2] and an α_1-antichymotrypsin-like inhibitor in rodents (H. Bauman, unpublished results) have failed. Thus, contrapsin and α_1-antichymotrypsin are probably equivalent, and we propose that the genes for contrapsin and α_1-antichymotrypsin are descendants of a single gene that have evolved, specifically within the reactive centre regions, to encode proteins with different activities. This has occurred since the time of rodent and primate divergence.

We thank Dr Jack Gauldie for helpful discussions and for communicating data, and Dr Lowell Sheflin for teaching the DNA sequencing techniques. We also thank Dr Derek Woods for supplying the human cDNA library.

Erythrocyte spectrin is comprised of many homologous triple helical segments

David W. Speicher & Vincent T. Marchesi

Department of Pathology, Yale University,
Yale University School of Medicine,
PO Box 3333, New Haven, Connecticut 06510, USA

Spectrin is an $\alpha\beta$ heterodimeric protein (molecular weight (M_r) = 460,000) which is a major component of the erythrocyte membrane skeleton[1-8]. The membrane skeleton also includes actin (band 5) and is attached to the membrane via non-covalent associations with two linking proteins[9-12]. Recently we have reported the amino acid sequence of a peptide of molecular weight 80,000 which comprises the NH_2-terminal one-third of the α subunit[13,14]. This α-subunit peptide contains multiple homologous non-identical sequences with a periodicity of 106 amino acids and an approximate molecular weight of 12,000. It was also established that spectrin is not related to any other proteins whose sequence was known. We now report additional amino acid sequence of peptides representative of other domains of both spectrin subunits. The results suggest that most of the human erythrocyte spectrin molecule is comprised of homologous segments with a 106 amino acid (M_r 12,000) length per segment. Each homologous 106-amino acid segment may be folded into a triple helical structure with a short non-helical region connecting adjacent units.

Amino acid sequences from the α and β subunits which exhibit homologous structure are presented in Fig. 1. The sequences of the first nine repeats are derived from the α-1 and α-2 domains and provide nearly complete sequence information on the NH_2-terminal half of the α subunit.

The degrees of homology between each of the sequences in Fig. 1 were analysed using the computer programs ALIGN and RELATE with either an identity or mutational data matrix. In all pairwise comparisons of sequences, homology was statistically significant (s.d. > 5), and there was no evidence for any repetitive structure smaller than 106 amino acids.

When all homologous sequences are compared as a group, only a single amino acid, tryptophan at position 45, is completely invariant in all sequences. A number of other positions (indicated by arrows in Fig. 1*a*) are strongly conserved and might have critical structural roles. A single amino acid predominates in each of these positions with occasional conservative substitutions. Positions 1, 12, 15, 26, 35 and 46 contain hydrophobic residues, but unlike other positions where any hydrophobic residue is permitted, these six positions exhibit a strong preference for I, W, L, L, F and I respectively (single-letter amino acid code). Several other highly conserved positions involve charged residues which might be involved in critical salt bridges. Arginine is preferred at position 22, lysine occurs at position 71 and aspartate predominates at positions 38 and 41. Either glutamate or aspartate occurs at position 48 in most sequences. Histidine is strongly conserved at positions 72 and 101.

Figure 2 summarizes available sequence information. So far, the sequence of 1,435 residues or 35% of the total molecule has been determined. If most of the spectrin molecule is composed of 106-amino acid repeat units, approximately 38 repeat units would be present. Evidence of 22 homologous repeat units throughout both subunits has already been obtained, thus it is likely that most of the spectrin molecule is made up of a single type of repetitive structure. The positions of known sequences are schematically represented in Fig. 2*b* and *c*. Repeat units have been numbered starting at the NH_2-terminal ends of the α and β subunits. The two subunits are aligned antiparallel with respect to NH_2-terminal orientation when in the dimer form[14-16]. The NH_2-terminals of both subunits are blocked but these blocked termini are removed during mild trypsin treatment, and both the α-T80 peptide and the β-T74 peptide have free NH_2-termini. The COOH-terminal region of the β subunit beyond repeat 18 in Fig. 2 contains the four covalent

Fig. 1 The 106-amino acid repeat unit. *a*, Homologous sequences of the α and β subunits were aligned using the computer programs ALIGN and RELATE as previously described[14] and are represented using the single-letter code. *b*, The locations of hydrophobic residues within the indicated α-subunit repeat units are represented. An extended hydrophobic series was used: ●—I, V, W, F, L, M, A, P; ◒—Y, C, G. *c*, The locations of charged residues in the indicated eight repeat units are represented. ●—E, D, K, R; ◒—H. The sequence (α-1' to α-6) of an α-subunit 80,000-dalton tryptic peptide previously named the α-I domain[13] and the sequence (α-7 to α-10) of a peptide of molecular weight 46,000 representing the α-II domain were determined using several overlapping groups of proteolytically cleaved peptides (D.W.S., G. Davis, V.T.M., manuscript in preparation). The remaining sequences with the exception of β-2, β-3 were obtained by extended automated Edman degradation of peptides which had previously been aligned by peptide mapping[15,28]. The sequencing methodology used here has been described previously[13]. The peptides were produced by mild proteolytic treatment[15], purified on two-dimensional gels and electroeluted[29], desalted by HPLC gel filtration in the presence of 0.2 M Tris-HCl, 8 M urea, 10 mM 2-mercaptoethanol *p*H 7.0 and dialysed extensively before sequence analysis. The amount of peptide used for sequencing ranged from 0.5 to 5 nmoles per run. Because some of these sequences represent a single extended run, the COOH-terminal portions of these sequences should be regarded as tentative. The β-2, β-3 sequence is from an 11,000-M_r CNBr fragment near the NH_2-terminal of the β subunit which bound to calmodulin columns in the presence of 6 M urea (D. E. Sears, J. S. Morrow, D.W.S. and V.T.M., manuscript in preparation). Unidentified residues are represented as X and tentatively identified residues are represented by lower case letters. Sequences from each subunit are presented in the order in which they occur in the total sequence, starting from the NH_2-terminal end of the polypeptide chain. Optimal alignment of all the illustrated sequences within the 106-residue repeat unit required only a single one residue gap in α-1 at position 59. There is no simple way to define the start point or phase of the repeat unit without knowledge of the gene structure. We had initially assigned the start point based on the tentative hypothesis that the first 17 residues of the α-T80 peptide (α-1') were unrelated to the rest of the molecule[14]. We have since found that statistically significant correlations of homology cannot be made on 17-residue segments. It is unlikely that this phasing correlates precisely with either the gene structure or protein conformational units (see text and Fig. 3), but the current convention will be retained until more definitive data are available. Many sequences illustrated here are continuous with the next line and can be read in the same manner as text that is, sequences which extend to the right end of a repeat unit are contiguous with the left end of the consecutively numbered repeat. This continuity and the approximate placement of remaining sequence segments within the two spectrin subunits is diagrammatically represented in Fig. 2. Arrows indicate positions within the repeat unit which are especially well conserved in all sequences presented.

phosphorylation sites characterized by Harris and Lux[16]. This region is ~10,000 daltons and has not been sequenced. It may be unrelated to the general spectrin repeat unit, because its amino acid composition is quite different from the compositions of peptides having homologous structure (refs 14, 16 and data not given). One segment of the α-subunit (α-10) also appears to be unrelated to the basic 106-repeat unit.

The presence of repetitive sequences within the spectrin molecule is not novel although the large number of intramolecular repeats is somewhat unusual. A number of proteins with internal repetitive structure have been identified, and current concepts of molecular evolution indicate that larger proteins have probably evolved from smaller precursors via gene fusions involving either unrelated genes or duplicated genes[17–20]. In the latter case the resulting larger proteins have internal repeats which undergo independent mutation, evolving to non-identical but homologous sequences. Presumably spectrin has evolved in such a manner, and the large number of repeats suggests that spectrin evolution involved many gene duplication and fusion stages.

a

Subunit	Total Residues	Residues Sequenced	Repeat Size	Total Possible Repeats	Identified Repeats
ALPHA	2100	1080	106	20	14
BETA	1950	355	106	18	9
TOTAL	4050	1435	106	38	23

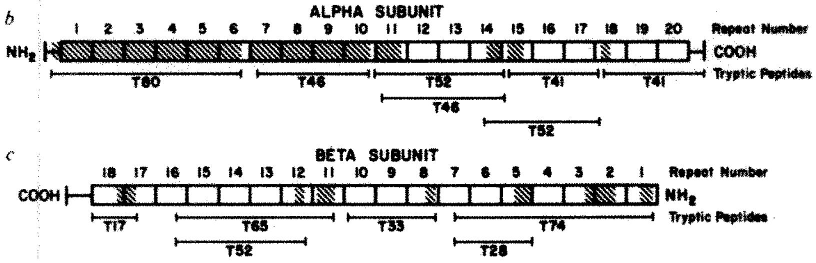

Fig. 2 Schematic representation of sequence positions within the spectrin subunits. ***a***, Summary of sequence analysis. Several sequences are known in addition to the sequences represented in Fig. 1. These include 90 residues of the sequence from the α-10 segment which is not homologous to the rest of the molecule, partial sequence of the remainder of α-6, and several other short sequences. For simplicity each of the 106-amino acid segments will be referred to here as a repeat unit, and the apparently unique α-10 which may have been related to the remainder of the molecule at one time (see text) will be referred to as a non-homologous repeat unit. ***b***, The α subunit (M_r 240,000) is represented as being made up of 20 repeat units (106 amino acids and 12,000 daltons per repeat) numbered starting at the amino-terminal end. Small regions near the NH_2- and COOH-termini are believed to contain binding sites and these may be unique and unrelated to the repeat unit (ref. 14 and text). The positions of known sequences are represented by the cross-hatched areas. The tryptic peptides which were used for sequence analysis are represented and have been aligned based on previous peptide mapping analysis[15,28]. The exact positions of sequences near the COOH-terminus of the α subunit are necessarily approximate and are based on three assumptions; (1) the α subunit is approximately 240,000 daltons and contains 20 repeats, (2) each repeat is 106 amino acids and approximately 12,000 daltons, and (3) several tryptic peptides overlap in repeat 14. This last assumption is the most tentative and is based on the consistently low yield of the T52 peptide encompassing repeats 14–17, the small number of spots on peptide maps involving repeat 14, and the fact that combined masses of the previously described domain peptides exceed the mass of the intact chain[15,28]. There may also be additional overlaps between peptides represented here which have not yet been detected. Therefore the assignment of the indicated sequence to repeats 14, 15 and 18 are provisional but their relative order should be accurate. ***c***, The β subunit (M_r 220,000) is comprised of 18 repeat units plus the phosphorylated region on the COOH-terminal end of the polypeptide chain. This subunit has been positioned antiparallel to the α subunit to illustrate their relative arrangement in the dimer, as the subunits associate side to side in an antiparallel orientation (see text). Repeats have been numbered starting at the NH_2-terminal end. The positions of known sequences shown are represented by the cross-hatched areas and tryptic peptides which were used as sources of material for sequence analysis are also represented. The most ambiguous location of sequence segments in this subunit is the placement of the 11,000-dalton CNBr fragment in repeats 2 and 3. Based on mapping data, this sequence could either occupy the indicated position or be translocated 106 amino acids towards the COOH-terminal end and occupy corresponding portions of repeats 3 and 4. Remaining assignments of sequences seem to be unambiguous based on repeat size, peptide size and previous mapping data.

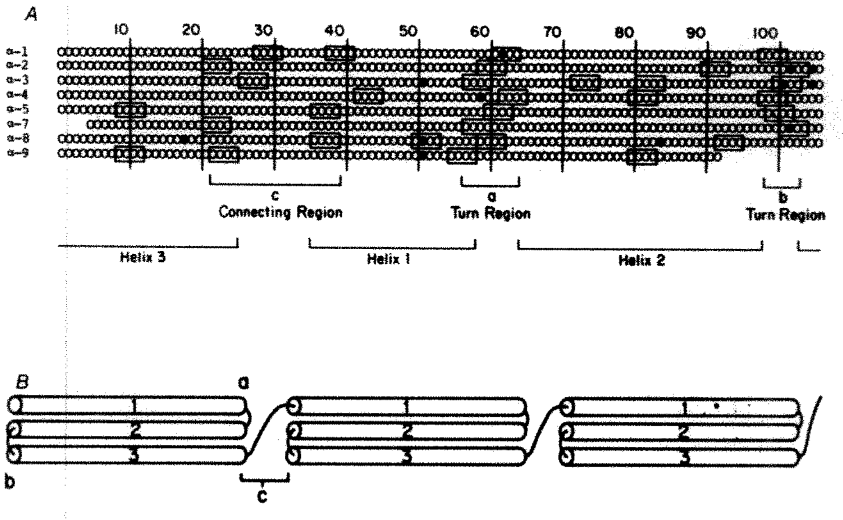

Fig. 3 Localization of reverse turns and connecting region within the 106-amino acid repeat unit. *A*, Diagrammatic representation of the eight repeat units of the α subunit corresponding to the sequences in Fig. 1. *B*, Three consecutive triple helical segments. The arrangement of helices, reverse turns (a and b), and the connecting region (c) between triple helical segments correspond to the similarly labelled regions of *A*. **Methods**: Reverse turns were calculated using P_α, P_β and P_T values, and positional frequencies for reverse turns as given by Chou and Fasman[22]. Average values of P_α, P_β and P_T were calculated over all possible 4-residue segments. Positional frequencies for reverse turns were calculated for 4-residue sequences with $P_\alpha < P_T > P_\beta$ and sequences with positional frequencies greater than 0.70×10^{-4} were scored as reverse turns if no other reverse turns with higher positional frequency values were predicted to occur within six residues. Two turn regions (a and b) were identified where most of the repeat units contained a predicted turn. A connecting region is also indicated where the helices probably break but are not in a turn configuration. Proline residues are indicated by shaded dots and the approximate locations of helical segments are given. It is quite likely that small amounts of other types of secondary structure also exist in the areas designated here as helices. One particularly interesting segment is between position 50 and 60 of the repeat unit. The entire segment between region c and turn a cannot be a single continuous helix in all repeats because three of the eight repeats in Fig. 4 have a proline at position 51. This would necessitate at least a kink in the helix at this point for these three repeats or it may signal a transition to another type of structure. Note that most of the repeats have a high β potential in this area[14].

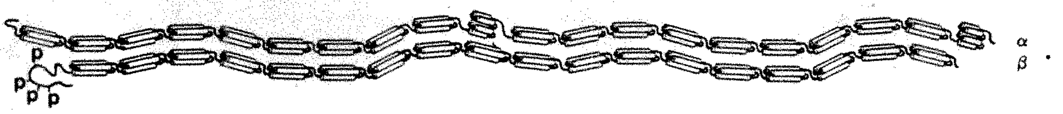

Fig. 4 A model of the spectrin dimer. The α and β subunits are composed of multiple triple helical segments connected by short non-helical regions. The subunits are antiparallel with the NH_2-terminus of the α subunit on the left. Each triple helical segment contains ~106 amino acids, corresponding to the periodicity observed from sequence data (Fig. 1). The tenth segment in the α subunit is not homologous and probably has a more compact globular structure and is represented here by shorter helices simply to illustrate a more globular structure. The twentieth segment of the α subunit may have a common evolutionary origin to the tenth repeat (data not given) and hence is represented in a similar manner. The COOH-terminal region of the β subunit contains four phosphorylation sites and may also be unrelated to the triple helical repetitive structure.

The Chou and Fasman predictive method[21,22] has previously been applied to an analysis of 595 residues of the α-1 domain[14]. This model can now be refined further, taking into account the existence of the 106-amino acid repeat throughout all domains of the molecule. Each of these repeats should have approximately the same conformation, as they were derived from a single ancestral gene, and it is well established that chain folding of related gene products is even more strongly conserved than amino acid sequence[19,20]. This preservation of chain folding within spectrin repeat units is also suggested by the well defined zones occupied by either hydrophobic or charged residues (Fig. 1*b*, *c*). In most positions where hydrophobic residues occur, the zones are especially well defined. Two additional properties of spectrin provide essential information on the nature of spectrin secondary structure. The intact molecule and the isolated subunits are highly α-helical (60–80%), with little or no β structure as determined by circular dichroism measurements[23,24]. In addition, the molecule is a long, thin, highly flexible rod ~1,000 Å in length[25,26], and this flexibility seems to be imparted by the presence of many hinge points throughout the length of the molecule. We also know that the NH_2-terminus is near one physical end of each subunit and the COOH-terminal is near the opposite end[14,15,27].

The eight repeat units presented in Fig. 1*b*, *c* were analysed further to determine a protein conformational model (Fig. 3). Turn regions (a and b) have been assigned to the two areas in the repeat unit where turns were predicted in most of the repeats. A connecting region c, corresponding to at least part of the region centred at residue 30, is probably a short non-helical loop. These three regions (a, b, c) divide the 106-amino acid repeat into three parts corresponding to the helices of a triple helical segment. The size of the basic structural unit coincides with the basic genetic unit.

A model emphasizing important structural features of the spectrin molecule is given in Fig. 4. The α and β subunits are both made up of many homologous segments. Each segment, which contains 106 amino acids (~12,000 daltons) is composed of a triple helical segment. The connecting region between adjacent triple helical segments is not helical and may provide the observed flexibility of the molecule. The two subunits are oriented in an antiparallel manner with the NH_2-termini at opposite ends of the dimeric molecule.

Crisis and Conservation: Conflict in the British Countryside.
By Charlie Pye-Smith and Chris Rose.
Penguin: 1984. Pp.213. Pbk £3.95.

FOURTEEN years ago, when the British arm of Friends of the Earth (FoE) was founded, the world seemed to be heading for environmental disaster. The Friends were a tiny band, valiantly trying to stem the surging tide of pollution and bring wisdom to the management of dwindling resources. Fortunately, things have not turned out to be quite as bad as was forecast. Food production per capita has significantly increased in many Third World countries and birth rates are falling. We still have oil and coal in abundance. The end of the world is not going to come from ozone depletion and although increasing carbon dioxide and acid deposition may result in severe local disruption, the effects are unlikely to amount to a global catastrophe. There is still much to be worried about but, given the political will, solutions to most environmental problems seem feasible.

If the Earth is likely to scrape by, it might be presumed that the environmentalists would lose their mission and momentum. But FoE, although remaining a relatively small group of activists, is still a force to be reckoned with. In Britain, today's environmental crisis is more about the kind of world people want to live in, how desires can be satisfied, hazards and nuisances removed and fears allayed, than it is about imminent global catastrophe. It is a shift in emphasis to which the campaigners have adjusted and the politicians are beginning to respond. The British Government has announced its intention to reduce lead in petrol and to introduce pesticide legislation. David Owen and David Steel, leaders of the Social Democratic and Liberal parties, have recently signed a Greenpeace statement on radioactive discharges, and in William Waldegrave we now have a minister who gives the impression of being for, and not merely of, the environment. Industry too is accommodating. Pesticide legislation has been welcomed by the British Agrochemicals Association and the Confederation of British Industry is agreeable to much greater public access to information on polluting discharges.

Britain has been fortunate in the style and leadership of its environmental lobby. Targets are chosen with care, the homework is done and the propaganda contains no greater misrepresentation or oversimplification than is the norm for more respectable and traditional lobbies. Although fundamentally serious, the campaigns have been witty and attractive, gaining broad public support.

In two of the chapters in *The Environmental Crisis*, Walter Patterson and Des Wilson recount the early and recent history of FoE. The battle roll extends from Rio Tinto Zinc, Schweppes returnable bottles, trade in endangered species, Save the Whale, recycled paper, allotments, Windscale, the Wildlife and Countryside Act and lead-free petrol to today's campaigns against Sizewell and pesticides, and for greater freedom of information. Many of them have been successful and most people would agree we are better off as a result.

Courtesy FoE.

The Friends at work, defending the Somerset Levels against agricultural interests in 1983.

The book is subtitled *A Handbook...* but this is a misnomer. Facts and figures are included but are only sufficient to get the campaigner into an argument; there is not enough to sustain a case against well-informed opposition. There is little new in the book for anyone expert in the field. It is better read as a series of essays — on pollution, wildlife, land use, transport, energy, conservation and waste — by leading figures in FoE.

The most eloquent contribution is Richard Sandbrook's chapter on the environmental debate. Whereas much of the rest of the book is parochial in scope, Sandbrook addresses the global issues. He attacks those in the environmental movement who seek the salvation of the world through the creation of numerous small, self-contained islands. The reality, he argues, is ecological and economic interdependence and, in consequence, there are few, if any, simple solutions to our problems. If we are to achieve a more sustainable and equitable world then there is no alternative to the hard grind of analysis and the energetic pursuit of solutions which, while not perfect, are at least a step in the right direction. One such step would be a sensible, long-term energy policy for Britain, and this proposal is well argued and supported in another chapter by Czech Conroy.

The most strident of the essays is by Chris Rose on "The Battle for the British Countryside". His arguments are elaborated in the second book reviewed here, *Crisis and Conservation*, co-written by Rose and Charlie Pye-Smith. This is a book about villains. Not surprisingly, chief among them are the farmers, forestry commissioners and water-authority members, together with their allies in the research institutes and universities. Less expectedly the Conservation Movement also comes under bitter attack. The Nature Conservancy Council, the Countryside Commissions and the Naturalists' Trusts are characterized as "dominated by people who are themselves farmers, foresters and landowners". Even FoE is criticized for being lured onto government committees.

The crime of this so-called "Old Guard" is that they believe farming and conservation can be reconciled. They seek consensus, cooperation and compromise while wildlife is being lost at an unprecedented rate. This seems to me unfair. There has been a long, and reasonably successful, tradition of voluntary agreements in British environmental policy. Such agreements, for example over the use of pesticides, can work providing the economic dice are not loaded against them. What *has* changed in the past few years has been the massive increase in the incentives for intensive farming consequent on Britain being subject to the Common Agricultural Policy (CAP). It is this which is making a policy of voluntary agreements ineffective and destroying the efforts of those who are working towards a compromise.

Pye-Smith and Rose provide a disturbing account of the destruction of British wildlife and habitats, but their book is weak on solutions. They believe planning controls are likely to be ineffective and they ignore the potential for changing the CAP. Their principal solution seems to be a land tax with exemptions for land of conservation or amenity value, yet there is no analysis of how this might work and it is not proposed with any confidence. The book ends with what amounts to a call for direct action: "Disorder, then, looks like being the order of the day". But disorder without policy or concrete solutions to put in place when the battle is won seems a mindless exercise. It will be a sad day if the environmental movement takes this road. ☐

Foundations: fiction in fact

David E. H. Jones

Ascent to Orbit: The Technical Writings of Arthur C. Clarke.
By Arthur C. Clarke.
Wiley: 1984. Pp.226. £14.95, $19.95.

WHAT makes a good science fiction writer? Apart from literary talent and uninhibited imagination, he needs one special gift. He must have a great knowledge and love of science, and yet not feel guilty if he is occasionally unfaithful to her. He must imagine, delight in and develop the consequences of things he knows to be scientifically incredible; yet to make them real he must embed them in a matrix of sound scientific understanding.

Few writers have these attributes, but Arthur C. Clarke is one of them. In dozens of stories, some of them major achievements of the genre, he has displayed his unruly imagination. Now in *Ascent to Orbit*, his collected technical works, he shows us his grasp of the rules.

The book brings together 24 technical articles spanning the years 1938–1981, on topics from electronics and astronomy to rocket theory and mathematical recreations. At its core is a cluster of about a dozen papers written between 1945 and 1950 on aspects of space technology. They form a sort of Old Testament in Dr Clarke's literary output: a foundation of rigorous theory in contrast to the later New Testament of wildly visionary science fiction. In them Dr Clarke, as a member of the British Interplanetary Society, is spokesman for a small band of enthusiasts preparing the way for a new technology. Escape velocities, the theory of rockets and their mass-ratio, transmitter powers necessary for interplanetary communication, theory of optimal orbital-transfer manoeuvres, are all here.

Among these papers is the brief, almost throw-away note which caused the whole book to be published. It is a privately-circulated two-page document dated May 1945 and entitled "The Space-station: Its Radio Applications". A few months later an expanded and now-famous version was published in *Wireless World*. In this paper Dr Clarke proposes the geostationary communications satellite, 20 years before the first one was put into orbit. This wonderful prevision of what is now the central technology of the "global electronic village" won him the 1982 Marconi Award for communication technology, which in turn inspired him to assemble the book. Dr Clarke modestly disclaims the title of "Father of Satellite Communications". He was, he insists, only its godfather.

It is tempting to scan this book for the seeds that were later to flower in his science fiction. There are some overt themes, of course: space travel itself, ion-drive rockets, lunar colonies. But more subtly, the grain and detail of his fiction seem informed by the same respect for scientific and technical truth that is shown here. My favourite piece is not on space travel at all: it is "You're on the Glide Path — I Think", an account of his wartime experience as a development engineer with the first ground-controlled approach radar for aircraft landing. Dr Clarke describes the authentic feel of development work: the cams that revolved once during every approach unless they fell off their shafts, the calibration markers that vanished or were mis-identified, the aerial-rotation unit that chose the precise crucial moment to strip its gears. This is the sort of formative experience, I suspect, that gives his science fiction stories their credibility.

Arthur C. Clarke is, of course, an excellent writer. His style is effortlessly lucid and humorous, his papers always a pleasure to read. Some of them (for example his "Dynamics of Space Flight", first published in 1949) might well form a good introduction to their topics even today. His comments on them, interspersed throughout the book, constitute an informal scientific autobiography which has a charm and interest of its own. One section describes his work as a physics-abstractor in 1949 and 1950: "I am proud of the fact that I appear as a distinct second-order differential coefficient on the curve 'Thousands of *Physics Abstracts* since 1900' in Derek J. de Solla Price's *Science Since Babylon*".

That was the last salaried job he held. His income from writing and broadcasting was rising, and he decided to make it his full-time career. His New Testament period was about to commence.

One might define a truly great science fiction writer as one who makes a dramatic technical prediction, incredible or absurdly visionary at the time, which within his lifetime actually comes true. By this criterion, Arthur C. Clarke and the communications satellite is up there with H. G. Wells and the atomic bomb. □

Mixed interferons

Robert M. Friedman

Interferons and Their Applications.
Edited by P.E. Came and W.A. Carter.
Springer-Verlag: 1984. Pp.575. DM 460, $178.50.

IN THE past few years the cloning of the genes for human beta and gamma interferon, and for the subtypes of genes for alpha interferon, has both increased the supply of these interferons for clinical studies and led to the initiation of critical experiments on the control of the expression of this gene family. Many groups are now investigating the biological roles of the already well-characterized enzymes and active metabolites associated with the interferon system. Relatively recently, interferons have also been recognized as important immunomodulators and cell growth inhibitory substances.

Because of this wide range of biological activities, the publication of *Interferons and their Applications* is timely. The volume attempts "to catalogue the current understanding of interferons from different biomedical disciplines" in order "to assist the growing community of laboratory researchers and students who may come to share [the editors'] enthusiasm for long term, in-depth study of the interferon systems".

Sadly, however, the book does not attain these objectives, because of the manner in which it has been compiled; it is made up of 27 chapters of widely varied character and quality. Some chapters are excellent reviews, some are for the most part reports of the author's own work, and others are philosophical discussions, but almost all of the contributions are too short to be really useful.

The difficulty of coordinating a large number of authors has also led to omissions, numerous repetitions and sometimes, even more unfortunately, to contradictions in the material presented. For instance, there is almost no discussion of the interesting effects of interferons on the replication of retroviruses. Extensive sections of Chapter 3 which deals with the evolution of interferon genes are repeated in Chapter 4 on comparative analysis of interferon structural genes. On p.73 of the latter chapter we read that: "It has clearly shown that the other human IFN-β genes are widely dispersed in the human genome", while the following chapter states: "In the contrast to the multigene family of Hu IFN-α, only a single Hu IFN-β gene has been found (p.85). Authors of other chapters specifically agree or disagree with each of these comments, thus compounding the confusion. Clearly a single discussion of the pros and cons of the thesis that there are multiple β interferon genes would have been more helpful.

Finally, the book has numerous typographical errors. All of the authors and the editors are culpable to varying degrees — but not many of them to the extent that they discuss work on "New Zeal and black (NZB) mice" (p.309). □

Mineral physics from Japan

Raymond Jeanloz

Materials Science of the Earth's Interior.
Edited by Ichiro Sunagawa.
Terra Scientific, Tokyo/Reidel: 1984.
Pp.653. Dfl. 340, $120, £80.

HOW much good science can be purchased for 8×10^8 yen (approximately $4 million at current rates)? Judging from this book, the answer is a lot.

Much of the leading research in mineral physics is being done in Japan, the work involving application of tools and principles from physics, chemistry, geology and materials science to the complex materials that make up our planet. *Materials Science of the Earth's Interior* summarizes research in mineral physics that was carried out during a three-year programme funded (with the amount mentioned) by the Japanese Ministry of Education. The programme was completed in 1981, and the book written in 1982, yet this volume is a remarkably up-to-date summary of work on the subject.

Although it emphasizes experiments over theoretical investigations, the book manages to cover a broad range of topics. For example, X-ray diffraction studies of silicate crystals and melts at temperatures up to $\sim$ 2,000°C are complemented by accounts of molecular dynamics calculations on molten silicates. Descriptions of techniques available for growing high-quality crystals, including diamond and other high-pressure phases, are followed by a number of studies on defects, rheology, diffusion and natural occurrences of the same minerals. High-pressure research is well represented, particularly in the areas in which the Japanese have excelled: the development and application of large-volume presses, *in situ* studies of phase transformations and determinations of complex phase equilibria. Also notable are individual contributions summarizing recent work on the theory of transition-metal compounds (Sugano and Ohnishi), the noble-gas geochemistry of natural diamonds (Ozima and co-workers), and the use of shock waves in high-pressure experiments (Syono and Goto). Overall, the articles bring together a great deal of material that was hitherto widely scattered or unavailable elsewhere in the literature.

The book will be especially interesting to the earth scientist who wants to know about advanced techniques that are now available and will become increasingly important in the study of geological materials. For the materials scientist or condensed-matter physicist, however, few clues are provided regarding the geological motivation for carrying out these studies; the connection between material properties and the evolution of planetary interiors is not explicitly examined. Still, the properties of complex inorganic systems such as minerals are of broad interest, and this book has allowed some of the leaders in mineral physics to describe frontier research in their field. ☐

Raymond Jeanloz is in the Department of Geology and Geophysics, University of California, Berkeley.

Beavering away

W.C. McGrew

Animal Architecture and Building Behaviour.
By Michael H. Hansell.
Longman: 1984. Pp.324. £25, $60.

TWENTY-THREE families of birds, from bulbuls to wrens, gather and use spider silk in constructing their nests. Beetles living in the Namib desert dig shallow trenches in the sand to trap dew for drinking water. Mole-rats burrow as a team, from the excavator in front, through the "conveyor belt" of intermediates, to the soil-expeller at the end of the queue. These are some of the splendid examples of animals building, as recounted by Michael Hansell. His book would be welcome if it were just an encyclopaedia of such habits, but it is much more.

A fifth of the text is taken up with a survey of animal architecture, across the minor builders from protozoa to chimpanzees, but focusing on the three main classes of major builders: spiders, insects and birds. The rest is devoted to analysis of architecture as action. As an ethologist, the author considers the structure to be inseparable from the behaviour which creates it. He is a great lister: artefacts may serve four functions, namely, protection from the elements, defence against other organisms, aids to subsistence, and communication and display. (A beaver's dam may perform all four.) There are seven methods of construction — sculpting, piling-up, moulding, rolling and folding, sticking-together, weaving, and sewing — birds, apparently, having the widest range. With such classificatory schemes, the author makes neat sense of a diverse array of knowledge, so that unexpected generalizations emerge; for example, the same properties of mud are exploited by organisms from termites to house martins.

For the scientist, animal artefacts have many uses. As products of behaviour they can be used to infer the qualities of the minds that produced them. They can persist long after the acts were performed, thus providing "frozen" or "fossilized" behavioural data. Some artefacts are sufficient to describe taxa the characteristics of which are otherwise completely unknown. Perhaps most impressive is that building has ramifications throughout the whole complexity of adaptation. Hansell argues convincingly that evolutionary changes in the choice of building materials may effect changes even in social structure; for example, in wasps the change from building with mud to building with vegetation allowed group sizes to increase and so for sociality to emerge.

The book is not without flaws. The author's special field of study is the house-building of caddis-fly larvae, and occasionally one feels that the book contains more than one ever wanted to know about these insects. By and large, vertebrates are under-represented compared with spiders and wasps — the use of hammer-stones by *Ammophila* wasps is mentioned four times, hammer-stone use by sea otters or chimpanzees not at all. The sleeping-nests of great apes rate only two sentences, despite an extensive literature which includes details of such things as the apparent use of dung as insulation against the cold by mountain gorillas!

A recurring problem is how wide to cast one's net, so to speak, in dealing with artefacts. The author is mostly interested in dwellings or other fixed structures, as his title suggests. Yet, at times, and seemingly arbitrarily, he inserts material on tool-use. The use of cafeteria-style trays by *Aphaenogaster* ants to carry off food is memorable, but why was this included when (for instance) probing with a cactus spine for insect prey by Galapagos finches was omitted? The author might better have left out tool-use altogether, as this has already been definitively dealt with in Benjamin Beck's *Animal Tool Behavior*, published by Garland in 1980 (for review see *Nature* **289**, 616; 1982). In fact, the two books are largely complementary and show many resemblances in emphasis and viewpoint.

Overall, this is a book of thoughtful analysis, always enlivened with entrancing details of natural history. Everyone knows of the marvellous bower-birds of the Antipodes. But who was aware that one species changes the flowers in its bower daily, or that another spends hours trimming leaves above its arena so that sunlight can penetrate, enabling the bird to show off its plumage? ☐

If you go down to the woods today...

Paul Richards

The Primary Source: Tropical Forests and Our Future.
By Norman Myers.
W. W. Norton: 1984. Pp.399. $17.95, £13.50.

TROPICAL forests are shrinking fast. Many believe that they may hardly survive into the next century, but books about them continue to multiply. Dr Myers's is only the latest in an outburst of publications which range from specialist volumes and authoritative texts, such as T.C. Whitmore's *Tropical Rain Forests of the Far East**, to semi-popular illustrated books and magazine articles.

The Primary Source is aimed mainly at non-specialists, but will also hold the interest of specialists. It is very readable and the author has the gift of explaining complex matters, such as the hydrological cycle of Amazonia, in simple, comprehensible language. Unlike most books on tropical forests, it is mainly concerned, not with the forests themselves, but with the impact of modern man on them — their destruction by commercial loggers, fuelwood gatherers, cattle raisers and shifting cultivators — as well as with their actual (and potentially much greater) contribution to human welfare. Dr Myers is well qualified to write about this topic: he has spent many years in Africa and more recently made a comprehensive survey of the current state of "forest conversion" in the humid tropical countries on behalf of the U.S. National Research Council's Committee on Research Priorities in Tropical Biology.

Dr Myers interprets the term "tropical forests" very widely; indeed, when he writes about the economic possibilities of water hyacinths and capybaras one wonders whether his subject is not really the whole flora and fauna of the tropics. The opening chapters ("Bio-ecological Background") are the only ones dealing with the forest as such; they emphasize its richness in species and its ecological complexity. Some statements here are questionable, for example that on p.81 that the seeds of very few tropical trees are wind-dispersed; this is not true and overlooks the function of natural gaps in rain-forest regeneration. Overall the purpose of these early chapters might have been better served had more space been given to illustrations and less to trying to convey a written picture of what a rain forest is "really" like.

In the next section we are on firmer ground. Much of the chapter on commercial logging is fairly familiar, but Dr Myers gives figures on the insatiable demand of the United States, Japan and other advanced countries for tropical hardwoods which are both striking and disquieting, not least because it is evident that present rates of consumption cannot be maintained; already some tropical countries, such as Nigeria, are reserving what remains of their hardwood stocks for their own use. It is even more disturbing that less than one-twentieth of tropical forests are under management of any kind. A survey of logging companies showed that not one of them leaves enough trees to act as seed-parents for natural regeneration. The accounts of the cattle ranchers and fuel gatherers are also full of information but are no more reassuring.

Still more horrifying is the chapter on shifting cultivators (whom Dr Myers calls "forest farmers"). At least 200 million people depend for survival on the temporary and relatively unproductive farming of small plots won by felling and burning tropical forests. Their numbers are rapidly increasing and have been swollen by incursions of squatters and dispossessed people who lack the simple skills of the traditional forest farmers and are thus even more damaging to the environment.

The effects of human demands on tropical forests might be less tragic if their resources were used fully and rationally. But as the chapters on "Contributions to our Welfare" show, this is far from true. In conventional tropical forestry, resources are classified into timber and "minor forest products". The latter now include such things as the steroid-yielding tubers of Mexican species of *Dioscorea* (yams) which are collected from wild plants in the forest and are an export worth millions of dollars. The future possibilities of discovering new drugs and insecticides in tropical forest plants may be enormous and others may provide templates or blue-prints from which such substances could be synthesized. Forest plants may also have uses as sources of protein and of "green gasoline" and other energy-yielding products. In order that the forest resources should be more completely, and less wastefully, used, Dr Myers suggests the establishment of "forest industrial complexes". Of course the products yielded by forests are not their only contribution to human welfare. Other chapters discuss their part in maintaining water supplies, and checking soil erosion and the silting of reservoirs, as well as their effects on the hydrological cycle, albedo and the carbon dioxide content of the atmosphere. The references on these and other topics are up to date and will be very useful for most readers, however expert.

Many readers will turn most eagerly to the final section of the book, "What We Can Do". The political, economic and biological problems are formidable, but Dr Myers thinks that there is much that can be done both by the citizens of tropical countries and by "outsiders". Basically he believes that the outlook would be brighter if tropical forests were valued at their true worth. Because they are undervalued, forestry departments have always been the Cinderellas of governments in tropical countries; agricultural departments are better supported, but often are more interested in cutting down than in conserving forests. More money is needed for forest protection and for research, and those who understand the importance of forests need to have an effective voice in governments.

Dr Myers sets out what all this implies in some detail, and even provides a "shopping list" for us outsiders which includes such activities as persuading giant corporations to do a better job for tropical forests. Gloomy though the prospects may seem, he remains optimistic, and points to success stories such as the more enlightened attitude to forestry in Indonesia and a change of policy in favour of forestry at the World Bank. But perhaps the most apposite message is the motto from Edmund Burke on the first page of the book: "Nobody makes a greater mistake than he who did nothing because he could do only a little". ☐

Paul Richards is Emeritus Professor of Botany in the University of Wales. He is author of The Tropical Rain Forest, *reprinted by Cambridge University Press in 1979.*

Effects of Aging on Regulation of Cerebral Blood Flow and Metabolism. C. FIESCHI, G.I. LENZI and C.W. LOEB (eds). *Karger: 1984. Pp.258. ISBN 3-8055-3805-7. $98.25.*

Enzyme Regulation by Reversible Phosphorylation — Further Advances (Molecular Aspects of Cellular Regulation Volume 3). P. COHEN (ed.). *Elsevier: 1984. Pp.250. ISBN 0-444-80525-7. $75.00.*

Essentials of Human Anatomy and Physiology. By ELAINE NICPON MARIEB. *Addison-Wesley: 1984. Pp.355. ISBN 0-201-15882-5. £16.15.*

Evolutionary Genetics of Fishes. BRUCE J. TURNER (ed.) *Plenum: 1984. Pp.636. ISBN 0-306-41520-8. Np.*

Family Physique and Fortune: A Study in Multifactorial Inheritance. By RICHARD W. PARNELL. *Parnell Publications: 1984. Pp.232. ISBN 0-9509466-0-5. £11.75.*

Fatty Acid Metabolism and Its Regulation. New Comprehensive Biochemistry, Vol.7 S. NUMA (ed.). *Elsevier: 1984. Pp.209. ISBN 0-444-805281. Np.*

Fetal Nutrition, Metabolism, and Immunology: The Role of the Placenta. RICHARD K. MILLER and HENRY A. THIEDE (eds). *Planum: 1984. Pp.387. ISBN 0-306-41639-5. Np.*

Flora of the British Isles. Illustrations. Vol.I Pteridophyta to Papilionaceau, Vol.II Rosaceae, Vol.III Boraginaceae to Compositae, Vol.IV Monocotyledons. By A.R. CLAPHAM *et al.* *Cambridge University Press: 1984. Pp.144, 119, 115, 119. Pbk ISBN 0-521-26962-8, 0-521-26963-6, 0-521-26964-4, 0-521-26965-2. Pbk £8.95, $17.95.*

Frogs of Western Australia. By M.J. TYLER *et al.* *Advance Press, Australia: 1984. Pp.109. Pbk ISBN 0-7244-9482-0. Pbk $A9.95.*

Function and Dysfunction of the Small Intestine: Proceedings of the Second George Durrant Memorial Symposium. By R.M. BATT and T.L.J. LAWRENCE. *Liverpool University Press: 1984. Pp.264. ISBN 0-85323-454-X. £22.50.*

Gas Chromatography, Mass Spectrometry, Applications in Microbiology. GORAN ODHAM *et al.* (eds). *Plenum: 1984. Pp.444. ISBN 0-306-41314-0. Np.*

General Microbiology: A Laboratory Manual. By JANE ANN PHILLIPS and THOMAS D. BROCK. *Prentice-Hall: 1984. Pp.234. ISBN 0-13-35062-6. Np.*

Genes and Antigens — The Monoclonal Antibody Approach. Contributions to Oncology 19. *Karger: 1984. Pp.192. ISBN 3-8055-3843-X. DM75, $37.75.*

Genetic and Environmental Factors during the Growth Period. C. SUSANNE (ed.). *Plenum: 1984. Pp.248. ISBN 0-306-41479-1. Np.*

La Genetique du Development. By JEAN-CLAUDE BEETSCHEN. *Presses Universitaires de France: 1984. Pp.127. ISBN 2-13-038052-2. Np.*

Giardia and Giardiasis: Biology, Pathogenesis, and Epidemiology. STANLEY L. ERLANDSEN and ERNEST A. MEYER (eds). *Plenum: 1984. Pp.407. ISBN 0-306-41539-9. Np.*

Humoral Factors in Host Defense. YUICHI YAMAMURA *et al.* (eds). *Academic: 1983. Pp.364. ISBN 0-127-68220-1. $32.*

Hydrocephalus. KENNETH SHAPRIO, ANTHONY MARMAROU and HAROLD PORTNOY (eds). *Raven: 1984. Pp.415. ISBN 0-89004-337-7. $93.*

Immunoassays of Steroids in Saliva. Ninth Tenovus Workshop. G.F. READ *et al.* (eds). *Alpha Omega Publishing: 1984. Pp.346. ISBN 0-900663-13.8. £15, $30.*

Inset Neurochemistry and Neurophysiology. ALEXEJ B. BORKOVEC and THOMAS J. KELLY (eds). *Plenum: 1984. Pp.523. ISBN 0-306-41511-9. Np.*

Insects on Plants: Community Patterns and Mechanisms. By D.R. STRONG, J.H. LAWTON and RICHARD SOUTHWOOD. *Blackwell Scientific: 1984. Pp.313. Hbk ISBN 0-632-00907-1; pbk ISBN 0-632-00909-8. Hbk £22, pbk £11.80.*

Integration of Ecological Aspects in Coastal Engineering Projects Part 1. B.A. BANNINK (ed.). *Pergamon: 1984. Pp.336. Pbk ISBN 0-08-031036-2. Pbk £88, $160.*

Isotopes and Radiation in Agriculture. Vol.2 Animals, Plants, Food and the Environment. M.F. L'ANNUNZIATA and J.O. LEGG (eds). *Academic: 1984. Pp.356. ISBN 0-12-436602-3. $75, £49.*

Learning, 2nd Edn. By A. CHARLES CATANIA. *Prentice/Hall: 1984. Pp.406. ISBN 0-13-527697-7. £24.65.*

Pineal Research Reviews, Vol. 1. R.J. REITER (ed.). *Alan R. Liss: 1983. Pp.276. ISBN 0-8451-3600-3. $56.*

The Role of Terrestrial Vegetation in the Global Carbon Cycle: Measurement by Remote Sensing. G.M. WOODWELL (ed.). *Wiley: 1984. Pp.247. ISBN 0-471-90262-4. £27.50.*

Science and Gender: A Critique of Biology and Its Theories on Women. By RUTH BLEIER. *Pergamon: 1984. Pp.220. Pbk ISBN 0-08030971-2. Hbk $25; pbk $12.50.*

Sensation and Perception, 2nd Edn. By STANLEY COREN, CLARE PORAC and LAWRENCE M. WARD. *Academic: 1984. Pp.606. Pbk ISBN 0-12-188554-2. Pbk $15, £10.50.*

The Shell Guide to Britain's Threatened Wildlife. By NIGEL SITWELL. *Collins: 1984. Pp.208. ISBN 0-00-219050-8. £8.95.*

Sleep and Breathing. NICHOLAS A. SAUNDERS and COLIN E. SULLIVAN (eds). *Marcel Dekker: 1984. Pp.613. ISBN 0-8247-7064-1. SwFr.213.*

Sudden Infant Death Syndrome. J. TYSON TILDON *et al.* (eds). *Academic: 1983. Pp.731. ISBN 0-12-691050-2. $45.*

Toxins and Plant Pathogenesis. J.M. DALY and B.J. DEVERALL (eds). *Academic: 1983. Pp.181. ISBN 0-12-200780-8. $21.50.*

Applied Biological Sciences

The Addictive Behaviours. HOWARD SHAFFER and BARRY STIMMEL (eds). *Haworth Press: 1984. Pp.172. ISBN 0-86656-243-5. $22.95.*

Advances in Clinical Neuropsychology, Vol. 1. GERALD GOLDSTEIN (ed.). *Plenum: 1984. Pp.189. ISBN 0-306-41502-X. Np.*

Advances in Immunobiology: Blood Cell Antigens and Bone Marrow Transplantation. JEFFREY McCULLOUGH and S. GERALD SNADLER (eds) *Alan R. Liss: 1984. Pp.462. ISBN 0-8451-0149-8. £44.00.*

Advances in World Diabetes Resarch: Reviewed Contents of 1982's Major Diabetes Congresses. By FRANCESCO BELFIORE and SILVIA IANNELLO. *Karger: 1984. Pp.258. ISBN 3-8055-3810-3. $99.00.*

Angiology: New Developments. P. BALAS (ed.). *Plenum: 1984. Pp.1288. ISBN 0-306-41349-3. Np.*

Antimalarial Drugs 1. Biological Background, Experimental Methods, and Drug Resistance. W. PETERS and W.H.G. RICHARDS (eds). *Springer-Verlag: 1984. Pp.484. ISBN 3-540-12616-3/0-387-12616-3. DM 370, $138.10.*

Antimalarial Drugs II. Current Antimalarials and New Drug Developments. W. PETERS and W.H.G. RICHARDS (eds). *Springer-Verlag: 1984. Pp.520. ISBN 3-540-12617-1/0-387-12617-1. DM 390, $145.50.*

Antineoplastic, Immunogenic and Other Effects of the Tetrapeptide Tuftsin: A Natural Macrophage Activator. V. NAJJAR and M. FRIDKIN (eds). *The New York Academy of Sciences: 1983. Pp.273. Hbk ISBN 0-89766-233-6; pbk ISBN 0-89766-233-4. Np.*

Aspirin and the Salicylates. By K.D. RAINSFORD. *Butterworths: 1984. Pp.335. ISBN 0-407-00316-9. £36.*

Bacterial Adhesion and Preventive Dentistry. S.A. LEACH *et al.* (eds). *IRL Press: 1984. Pp.230. Pbk ISBN 0-904147-63-0. Pbk £20, $40.*

Bacterial Infections of Humans: Epidemiology and Control. ALFRED S. EVANS and HARRY A. FELDMAN (eds). *Plenum: 1982. Pp.702. Pbk ISBN 0-306-41705-7. Np.*

Benzoidazepine Recognition Site Ligands: Biochemistry and Pharmacology. Advances in Biochemical Psychopharmacology, Vol.38. G. BIGGIO and E. COSTS (eds). *Raven: 1983. Pp.272. ISBN 0-89004-432-5. $38.50.*

Biochemical Basis of Chemical Carcinogenesis. HELMUT GREIM *et al.* (eds). *Raven: 1983. Pp.325. ISBN 0-89004-961-0. $68.50.*

The Biochemical Mode of Action of Pesticides 2nd edn. By J.R. CORBETT, K. WRIGHT and A.C. BAILLIE. *Academic: 1984. Pp.382. ISBN 0-12-187860-0. £35.00, $59.00.*

Biological Responses in Cancer: Progress Toward Potential Applications. Volume 2. ENRICO MIHICH (ed.). *Plenum: 1984. Pp.245. ISBN 0-306-41583-6. Np.*

Cancer Invasion and Metastasis: Biologic and Therapeutic Aspects. G. NICOLSON and L. MILAS (eds). *Raven: 1984. Pp.501. ISBN 0-89004-896-7. $81.*

Central Cardiovascular Control: Basic and Clinical Aspects. Current Topics in Neuroendocrinology. D. GANTEN and D. PFAFF (eds). *Springer-Verlag: 1983. Pp.192. ISBN 3-540-11350-9/0-387-11350-9. DM 90, $35.*

Chronic Diarrhoea in Children (Nestle Nutrition Workshop Series, Volume 6). EMANUEL LEBENTHAL (ed.). *Raven: 1984. Pp.588. ISBN 0-89004-319-1. $49.00.*

Contemporary Hematology/Oncology, Vol.3. ALBERT S. GORDON, JOSEPH LOBUE and ROBERT SILBER (eds). *Plenum: 1984. Pp.271. ISBN 0-306-41535-6. Np.*

Continuous Culture: Biotechnology, Medicine and the Environment. A.C.R. DEAN, D.C. ELLWOOD and C.G.T. EVANS (eds). *Wiley: 1984. Pp.322. £35, $60.50.*

Control of Virus Diseases. EDOUARD KURSTAK (ed.). *Marcel Dekker: 1984. Pp.584. ISBN 0-8247-7066-8. SwFr. 320.*

Current Issues in Toxicology: Age-Associated (Geriatric) Pathology. Its Impact on Long-Term Toxicity Studies. H.C. GRICE (ed.). *Springer-Verlag: 1984. Pp.114. Pbk ISBN 3-540-12845-X/0-387-12845-X. Pbk DM 35, $13.60.*

Diseases of the Lymphatic System: Diagnosis and Therapy. DAVID W. MOLANDER (ed.). *Springer-Verlag: 1984. Pp.340. ISBN 3-540-90850-1/0-387-90850-1. DM 192, $71.70.*

End-Stage Renal Disease: An Integrated Approach. W.J. STONE and P.L. RABIN (eds). *Academic: 1983. Pp.373. ISBN 0-12-672280-3. $55.*

Environmental Aspects of Cancer: The Role of Macro and Micro Components of Foods. ERNST L. WYNDER *et al.* (eds). *American Health Foundation: 1983. Pp.295. ISBN 0-917678-17-6. $65.*

Experimental Allergic Encephalomyelitis: A Useful Model for Multiple Sclerosis. Progress in Clinical and Biological Research, Vol.146. ELLSWORTH C. ALVORD, MARIAN W. KIES and ANTHONY J. SUCKLING (eds). *Alan R. Liss: 1984. Pp.554. ISBN 0-8451-0146-3. Np.*

Growth of the Heart in Health and Disease. RADOVAN ZAK (ed). *Raven: 1984. Pp.490. ISBN 0-89004-734-1. $98.*

Human *in Vitro* Fertilization and Embryo Transfer. DON P. WOLF and MARTIN M. QUIGLEY (eds). *Plenum: 1984. Pp.440. ISBN 0-306-41623-9. Np.*

Hydroxyanisole: Recent Advances in Anti-Melanoma Therapy. P.A. RILEY (ed.). *IRL Press: 1984. Pp.248. Pbk ISBN 0-904147-64-9. Pbk £19, $38.*

Hypertension and the Angiotensin System: Therapeutic Approaches. AUSTIN E. DOYLE and ALEXANDER G. BEARN (eds). *Raven: 1984. Pp.320. ISBN 0-89004-309-4. $49.*

Manipulation and Expression of Genes in Eukaryotes. PHILIP NAGLEY *et al.* (eds). *Academic: 1983. Pp.386. ISBN 0-12-513780-X. $41.*

Measurement in Clincal Respiratory Physiology. By GABRIEL LASZLO and MICHAEL F. SUDLOW. *Academic: 1983. Pp.337. ISBN 0-124-37080-2. $60.*

Nucleic Acid Research: Future Development. KIYOSHI MIZOBUCHI, ITARU WATANABE and JAMES D. WATSON (eds). *Academic: 1983. Pp.586. ISBN 0-125-01650-6. $65.*

Perspectives in Cardiovascular Research, Vol. 10. Clinical Pharmacology of Antiarrhythmic Therapy. BENEDICT R. LUCCHESI, JAMES V. DINGELL and RICHARD P. SCHWARZ (eds). *Raven: 1984. Pp.275. ISBN 0-89004-966-1. $56.*

Pituitary Hyperfunction: Physiopathology and Clinical Aspects. F. CAMANNI and E.E. MULLER (eds). *Raven: 1984. Pp.448. ISBN 0-89004-968-8. $99.50.*

Recent Results in Cancer Research: Early Detection of Breast Cancer. S. BRUNNER, B. LANGFELDT and P.E. ANDERSEN (eds). *Springer-Verlag: 1984. Pp.214. ISBN 3-540-12348-2/0-387-12348-2. DM 108, $40.30.*

Recombinant DNA and Medical Genetics. ANNE MESSER and IAN H. PORTER (eds). *Academic: 1983. Pp.207. ISBN 0-124-92220-1. $29.*

The Reproduction Revolution: New Ways of Making Babies. By PETER SINGER and DEANE WELLS. *Oxford University press: 1984. Pp.273. Hbk ISBN 0-19-217736-2; pbk ISBN 0-19-286044-5. Pbk £2.95; hbk £12.50.*

Respiratory Medicine for Primary Care. CHARLES W. DRAGE (ed.). *Academic: 1983. Pp.231. ISBN 0-127-88165-4. $29.95.*

Targets for the Design of Antiviral Agents. E. DE CLERCQ and R.T. WALKER (eds). *Plenum: 1984. Pp.378. ISBN 0-306-41618-2. Np.*

Treatment of Hyperlipoproteinemia. LARS A. CARLSON and ANDERS G. OLSSON (eds). *Raven: 1984. Pp.304. ISBN 0-89004-341-8. $60.00.*

Ultrasound: Biological Effects and Potential Hazards. By A. ROY WILLIAMS. *Academic: 1983. Pp.321. ISBN 0-12-756960-X. $49.50.*

Viral Hepatitis and Delta Infection. Progress in Clinical and Biological Research, Vol. 143. GIORGIO VERME *et al.* (eds). *Alan R. Liss: 1984. Pp.448. ISBN 0-8451-0143-9. £41.*

Visual Disorders in the Handicapped Child. Pediatric Habilitation, Vol.5. By JOHN L. GOBLE. *Marcel Dekker: 1984. Pp.287. ISBN 0-8247-7109-5. SwFr. 127.*

History of Science

Darwin, Marx and Freud: Their Influence on Moral Theory. ARTHUR L. CAPLAN and BRUCE JENNINGS (eds). *Plenum: 1984. Pp.230. ISBN 0-306-41530-5. Np.*

General

Black Apollo of Science: The Life of Ernest Everett Just. By K.R. MANNING. *Oxford University Press: 1983. Pp.397. ISBN 0-19-503299-3. $29.95.*

Bulimarexia: The Binge/Purge Cycle. By MARLANE BOSKING-WHITE and WILLIAM C WHITE Jr. *W.W. Norton: 1984. Pp.219. ISBN 0-393-01650-1. £12.50, $18.00.*

Cancer Rehabilitation. ALBERT E. GUNN (ed.) *Raven: 1984. Pp.237. ISBN 0-89004-989-0. $47.50.*

Nucleic acids and related areas

The new chemicals and apparatus described this week are mainly for those working with recombinant DNA technology.

- Now available from Worthington, the Type II restriction endonuclease *Cpf*I (from *Clostridium perfringens*) is an isoschizomner of *Sau*3AI and *Mbo*I which cleaves DNA leaving the 5′ terminal extension GATC like *Sau*3AI, *Bam*HI, *Bgl*II and several other enzymes. Like *Sau*3AI, *Cpf*I cleaves DNA that is adenine methylated. The best conditions are 10 mM Tris-HCl, *p*H 7.5, 100 mM NaCl, 10 mM $MgCl_2$, 10 mM β-mercaptoethanol and 100 $\mu g\ ml^{-1}$ bovine serum albumin at 37°C. It is supplied at 5–10 units μl^{-1} in package sizes of 200 units, 500 units or 1,000 units.

Circle No. 100 on Reader Service Card.

- Boehringer Mannheim has recently introduced three DNA-affinity ligands which have been developed specially for the sequence specific electrophoretic separation of DNA fragments. By the use of two-dimensional gel systems, DNA fragments of differing base composition may be separated according to their retarded mobilities in the presence of a particular ligand. After separation the ligand can be removed, yielding the unmodified DNA. Also available from Boehringer Mannheim is a top quality Ribonuclease H. The enzyme is particularly suited to cDNA preparation. The absence of endonucleases and nicking actively is routinely checked by incubation with λ DNA and pBR322 DNA followed by gel electrophoresis. Absence of RNaseIII and RNase is checked by incubation of the enzyme with tritiated poly (U) poly (A) and MS 2RNA.

Circle No. 101 on Reader Service Card.

- Bio-Rad's new Mini-Sub submarine electrophoresis cell speeds the separation of DNA restriction fragments and other nucleic acids. Using very small sample loads, high resolution is obtained in runs of only 10 cm, taking only 30 min to 2 h. Effective separations of *Eco*RI or *Hin*dIII digest of λ phage DNA have been performed at 175V in as little as 20 min. Using sample loads as small as 50 ng, as little as 1–5 ng of DNA can be detected in agarose gels with ethidium bromide, while as little as 500 pg of DNA can be detected in polyacrylamide gels using the Bio-Rad Silver Stain. The Mini-Sub cell's increased speed and sensitivity simplifies many procedures. For example, clones can be screened rapidly for proper recombinant inserts, DNA enzymes can be assessed for activity, and DNA ligations, and other DNA modifying reactions can be monitored quickly.

Circle No. 102 on Reader Service Card.

- Terminal transferase and AMV reverse transcriptase are now available from Boehringer Mannheim. Both enzymes are extensively tested for the absence of endonucleases, exonucleases and nicking activities. Boehringer also markets SP-6 polymerase and SP-62 PL plasmid DNA. The SP-6 polymerase system generates single RNA species of known genetic origin in large quantities. These RNAs may be used as highly specific probes in blot and *in situ* hybridizations and as substrates in RNA transcription studies and S_1 mapping experiments. The enzyme is supplied free of contaminating endonucleases, exonucleases, nicking activities and ribonucleases. Restrictions endonuclease *Asp*718 (G/GTACC) is also available from Boehringer Mannheim. *Asp*718 is an isochizomer to *Kpn*1, but produces fragments with 5′-cohesive ends as opposed to the 3′-cohesive ends from *Kpn*1.

Circle No. 103 on Reader Service Card.

- A new 24-page catalogue includes detailed descriptions and prices for Becton Dickinson's complete line of monoclonal reagents, kits and panels for enumerating and identifying human and mouse leukocytes and immunoglobulins. Second-step reagents and monoclonal controls are also listed.

Circle No. 104 on Reader Service Card.

- A comprehensive range of restriction endonucleases, DNA vectors and modifying enzymes is marketed by Genetic Research Instrumentation of Bishop's Stortford, UK. The company also offers a complete range of instruments and biochemicals for all aspects of molecular biology — for plant cells as well as animals and microbes. The new range of enzymes is added to the existing range of plant protoplast enzymes.

Circle No. 105 on Reader Service Card.

- The new Schleicher and Schuell Mini-Collodion Membrane is designed for quick, efficient, and simultaneous concentration and dialysis of protein and nucleic acids in small sample quantities. A microtapered collection tip yields sample recoveries of up to 98% with concentrations down to 10 μl. The Mini-Collodion Membrane has a volume of 2 ml and molecular weight cut-off at 25,000. Simultaneous concentration and dialysis can be achieved simply by using the membrane in conjunction with an easy-to-assemble S&S all-glass apparatus and the membrane can also be used without the specialized apparatus for dialysis. Short sample preparation times are possible because of the high surface area-to-volume ratio.

TWO NEW reliable, up-to-date and complete biotechnology information resources.

EXAMINE ON FREE APPROVAL WITHOUT COMMITMENT

Detailed information on every aspect of biotechnology worldwide

An indispensable guide to: ★ Products, services and research ★ Companies ★ Government and international agencies ★ Information sources

THE INTERNATIONAL BIOTECHNOLOGY DIRECTORY 1984 —

- is thoroughly international
- features a unique BUYER'S GUIDE to products, research and services
- covers both the old and new biotechnologies

The Directory tells you:

★ Who your competition is, and what they are doing.

★ Who are potential customers and suppliers.

★ Where to buy equipment, chemicals and services.

★ Where culture collections are located and what cultures they hold.

★ Who imports/exports biotechnology products in over 20 countries.

★ Which government departments are associated with biotechnology.

All compiled by the eminent biotechnologist Dr. Jim Coombs and now available to you on **FREE APPROVAL.**

Macmillan Hardcover 400pp
November 1983
ISBN 0 333 35140 1
£50.00/A$100.00

Information Sources in Biotechnology

★ covers both old and new technologies

★ covers technical and commercial literature

★ covers difficult and hard to trace sources

★ includes over 20 at-a-glance evaluation tables

★ provides an Index of publishers and their addresses

Dr. Crafts-Lighty, Head of Information and Library Services at Celtech Limited, systematically and critically reviews all the important information sources:

• books • conferences • trade periodicals • research periodicals • computer databases • patent • market surveys • directories • organisations • secondary sources

Macmillan Paperback 320pp
September 1983
ISBN 0 333 36178 4
£40.00/$80.00

Single- and double-stranded DNA eluting on a Bio-Gel hydroxlapatatite column, and a new DNA sequencing device from Atto.

• Hydroxylapatite is often used to characterize DNA hybrids and to study reassociation kinetics. To simplify its use in these applications, each bottle of Bio-Gel hydroxylapatite shows the conditions for optimal separation of single and double-stranded DNA on the label. To find the conditions, heat-denatured (single-stranded) and native (double-stranded) calf thymus DNA are combined, applied to the hydroxylapatite colulmn in 0.01M sodium phosphate, *p*H 6.8 at 25°C, and eluted with a gradient of increasing phosphate concentration. On the above graph, point A is the concentration at which single-stranded DNA elutes. Double-stranded DNA elutes at point B. The numerical value for the phosphate concentration at both points is given. Because all the information needed for the selection of the right conditions for each separation comes with the hydroxylapatite, it is possible to perform procedures faster by eliminating the use of a continuous gradient.

• American Bionuclear's DNA Synthesis Grade diisopropyl phosphoramidites is suitable for preparing synthetic oligonucleotides using either manual or automated procedures. Each preparation is more than 98% pure based on ^{31}P NMR and TLC analysis. Functional tests conducted on each lot guarantee greater than 95% coupling efficiency. A detailed quality control assay report is included with each shipment. The diisopropyl phosphoramidites are distributed in septum vials designed to fit commercially available automated DNA synthesizers.

Circle No. 108 on Reader Service Card.

• Atto's new DNA sequencing apparatus is highly versatile, being adjustable for both width and height. It accommodates plates from 200 mm high by 100 mm wide to 1 m high by 300 mm wide. The air cooling system controls 'smile' effects, and avoids the 'hot spots' common to fully enclosed systems. Large 1.5 litre compartments avoid problems of buffer breakdown and circulation ports are provided. A single acrylic clamp bar retains the plates securely in position, assuring leak-free sealing and ease of operation. Physical make/break safety lids are standard and connect to taut protectively housed platinum electrodes. The separation unit is of the functional sliding type, extremely effective in preventing discontinuities caused by air bubbles, to aid gel preparation.

Circle No. 109 on Reader Service Card.

• Schleicher & Schuell's "Quick Blot Kit" is a highly selective, quantitative and rapid method for the purification and immobilization of multiple samples of mRNA onto nitrocellulose. mRNA isolated from small volumes of whole cells, bacteria and virus can be hybridized, translated, reverse-transcribed or released and manipulated. The mRNA is tightly bound and always remains biologically active as no baking of the membrane is required. The system takes advantage of the high selectivity of nitrocellulose for mRNA which has been dissolved in concentrated NaI. Under these conditions and at low temperatures, adsorption of mRNA is very high whilst rRNA, tRNA, tRNA, native and denatured DNA, as well as proteins do not co-immobilize.

● D-Gel, a new product from Tekmar, will rapidly and efficiently extract nucleic acids from gels. This electrophoretic transfer system will directly transfer nucleic acids to DEAE-cellulose, or DEAE anion-exchange resin. DNA can then be recovered rapidly and intact in a quantitative yield, free from contaminating gel impurities, for assured biological activity in subsequent enzymatic reactions. The system ensures a high recovery efficiency — nanogram to submilligram quantities — with no danger of cross contamination. Utilizing isolated and removable transfer chambers, the D-Gel system is compatible with standard laboratory power supplies.

Circle No. 111 on Reader Service Card.

● New additions to Cappel's range of affinity gells are anti-mouse IgG(H&L) coupled to Sepharose 4B and anti-rat IgG(H&L) coupled to Sepharose 4B. The antibodies are affinity purified and the mouse affinity gel will bind mouse IgG1, IgG2a, IgG2b, IgG3, IgM and IgA; the rat IgG affinity gel will bind rat IgG1, IgG2a, IgG2b, IgG2c and IgM. Affinity gels are useful for purification of mouse or rat immunoglobulin as well as immunoprecipitation of any IgG subclass mouse or rat monoclonal antibodies. These gels may also be used in columns for the same purposes. Each millilitre of gel has bound to it 2.0 mg of active affinity purified antibody resulting in a binding capacity of 1.0 to 1.75 mg ml^{-1} of IgG.

Circle No. 112 on Reader Service Card.

● The new DNA sequencing system from American Bionuclear is available in two versions: SQU-1000 (20 cm width) and SQU-2000 (33 cm width). Both are fully adjustable to provide the flexibility of running sequencing gels from 20 cm to 1 m in length. Both models feature adjustable upper buffer reservoirs, a 'no leak' gasket system of high compression silicone tubing that guarantees a tight seal and leak-free direct buffer–gel contact. Ports on both the upper and lower reservoirs permit buffer re-circulation, and a wide range of accessories is available for both models.

Circle No. 113 on Reader Service Card.

● The LKB 2301 Macrodrive 1 power supply is intended for low-voltage electrophoresis applications. Using a few simple switches and clear, easy-to-read LED displays, the required constant voltage (0–1,000 V), current (0–400 mA) and integral digital timer (0–60 hours) can be quickly set. The Macrodrive 1 is well suited for routine PAGE, SDS, disc and gradient gel electrophoresis, as well as immunoelectrophoresis.

Circle No. 114 on Reader Service Card.

● Purpose-built for the new blotting techniques the Desatronic 200/1000 (0–200 V/O-1,000 mA) power supply is available from Desaga GmbH of Heidelberg. Also new is the Desatronic 6000/100 for isoelectric focusing. Voltage, current and wattage are regulated automatically; all parameters are digitally displayed.

ANNOUNCEMENTS

Awards

Professor K.D. Cole of Latrobe University, Melbourne, Australia, has been awarded the 1984 **Appleton Prize** for Ionospheric Physics by the Royal Society UK, in recognition for his contributions to understanding the fundamental processes taking place in the magnetosphere.

The Royal Society has also elected the following as new Foreign Members: **Professor P-G. De Gennes**, Professor at the Collège de France, Paris, in recognition of his many major contributions to theoretical physics — in the fields of magnetism, superconductivity, liquid crystals, polymers and mixed fluid flows; **Professor R. Hoffmann**, John A. Newman Professor of Physical Science at Cornell University, Ithaca, New York, USA, in recognition of his contributions to theoretical chemistry, particularly as originator of the extended Huckel theory; **Professor M. Meselson**, Cabot Professor of Natural Science, Harvard University, Cambridge, Massachusetts, USA, in recognition of his first demonstration of semiconservative DNA replication and for his studies on the mechanism of genetic recombination; **Professor G.E. Palade**, Professor of Cell Biology at Yale Univesity, New Haven, Connecticut, USA, in recognition of his investigations of the ultrastructure of biological cells, and notably the description and the delineation of the functions of the endoplasmic reticulum; **Professor C. Rubbia**, Professor of Physics, Harvard University, Cambridge, Massachusetts, USA, and Senior Research Officer, CERN, Geneva, Switzerland, in recognition of his work as an initiator of important experiments in new areas of high energy physics, and **Professor H.H. Ussing**, Professor of Biochemistry at the University of Copenhagen, Denmark, in recognition of his work on the active and passive transport of ions across cell membranes and on the functioning of secretory epithelia.

Emeritus Professor Sir Alan Harris, FEng of Imperial College London, has been awarded the Gold Medal of the Institution of Structural Engineers.

Professor J.T. Stuart, FRS, Head of the Department of Mathematics at Imperial College, has been awarded the Whitehead Prize of the London Mathematical Society.

Professor Michael Sela, President of the Weizmann Institute of Science, **Professor Louis Chedid** of the Pasteur Institute, Paris and **Professor Edgar Lederer** of the French Academy of Science, have been jointly awarded the Prix de l'Institut de la Vie by the Fondation Electricité in France for their elucidation and perfection of the production of synthetic vaccines and the adjuvants of immunity.

Mr Erik Quistgaard, Director General of the European Space Agency, has been presented with the NASA Distinguished Public Service Medal.

Dr Richard Beasley of Wellington University, New Zealand, has been awarded the first two-year fellowship by the Wellcome Trust in association with the Medical Research Council of New Zealand, to study factors underlying asthma — at the Department of Medicine, Southampton University.

Appointments

Sir Alec Merrison and **Professor L.A. Thomas** have been elected President and Vice-president, respectively, of the Institute of Physics, London.

Dr John Midwinter, Head of the Optical Communications Technology Division of British Telecom, has been elected to the British Telecom Chair of Optoelectrics at the Department of Electronic and Electrical Engineering, University College London.

Professor Brian May, Head of Silsoe College, Bedfordshire, UK, has been elected President of the Institution of Agricultural Engineers.

Professor Guillermo Soberón Acevedo, Secretary of Health and Welfare, Mexico, has been elected President of the 37th Annual Session of the World Health Assembly (WHO), Geneva, Switzerland.

Professor Edwin C. Cadman, MD, Professor of Medicine at the University College of San Francisco, has been elected to the presidency of the American Federation of Clinical Research.

Dr Gordon H. Sato, Director of the W. Alton Jones Cell Science Center, has been elected a Member of the National Academy of Sciences, USA.

James F. McDonald has been elected President and chief operating officer of Gould Electronics, Illinois, USA, while **David Simpson** has been elected vice-chairman of the board.

Professor Roderick N.M. McSween has been appointed to the Chair of Pathology at the University of Glasgow; also at Glasgow University, **Professor Kenneth C. Calman** has been appointed to the Chair of Postgraduate Medical Education and the Deanship of Postgraduate Medicine, and **Dr Miles D. Hounsley** has been appointed to the Gardiner Chair of Biochemistry.

Professor Gilmour Toner has been appointed to the Musgrave Chair of Pathology, and **Dr Ronald Henry Perrott** to the Chair of Software Engineering at the Queen's University of Belfast, Northern Ireland.

Professor Bryan Carsberg of the London School of Economics has been appointed as Director General of Telecommunications, UK.

Dr John Rose, a Director of Dainichi Sykes Robotics Ltd, has been appointed to the United Kingdom's first University chair in automated manufacturing technology at the University of Salford.

Arnold Allen, CBE, a Chief Executive at the UK Atomic Energy Authority, has been appointed its full-time Chairman.

Michael Bown, formerly Group President in charge of International Operations at Peabody International Corporation, has been appointed as the the first Director of CEED – the UK Centre for Economic and Environmental Development.

Dr George Russell, Senior Lecturer in the Department of Electrical and Electronic Engineering, Heriot–Watt University, has been appointed to a new Professorship within that Department.

Dr Bernard Wegener has been appointed Managing Director of Merrell Dow Pharmaceuticals GmBH, Ruesselsheim, West Germany.

Dr Bernard Hyams of the UK has been appointed by the Council of CERN – The European Laboratory for Particle Physics near Geneva, Switzerland – as the new head of the Experimental Physics Division.

Erich Bloch, currently Vice President for Technical Personnel Development at IBM, has been appointed Director of the National Science Foundation (NSF).

Dr Moustafa T. Chahine has been appointed to the position of Chief Scientist at the Jet Propulsion Laboratory (JPL), NASA, California; he is currently Manager of the Earth and Space Sciences Division at JPL.

Paul F. Engstrom, MD, has been named vice-president of Cancer Control and Continuing Education at the Fox Chase Cancer Center in Philadelphia, USA.

Paul Beeson MD, **Charles K. Donegan MD**, **Adrian Ostfeld MD**, **James Neel MD**, and **Dr Martha Storandt** have been appointed as new members of the National Advisory Council on Aging, USA.

Short Courses

Autumn 1984, **Continuing Engineering Education Program** organised by the George Washington University; London, Copenhagen, Dusseldorf, Frankfurt (Mr Michael Keenan, Manager, The George Washington University Continuing Engineering Education Program, 18 St. George's Street, Hanover Square, Mayfair, London W1R 9DE, UK).

18-20 September, **Introduction to Reinforced Plastics**, (Short Course Office (IFRP), Department of Mechanical Engineering, University of Sheffield, Mappin Street, Sheffield S1 3JD, UK).

24-27 September, **Programming in Pascal** and 23-25 October, **Control of Mechanical Systems** (The Registrar, The University of Manchester Institute of Science and Technology, PO Box 88, Manchester M60 1QD, UK).

17-19 October, **Basic High Performance Liquid Chromatography Course**, (Chrompack UK Ltd., Unit 4, Indescon Court, Millharbour, London E14 9TN).

19-22 November, **Training Course in Fluid Rheology** (Mr L.J. Viney, Warren Spring Laboratory, Gunnels Wood Road, Stevenage, Hertfordshire SG1 2BX, UK).

How valuable is the student grant?

from Richard Pearson

The student grant in the United Kingdom has been severely devalued by the effects of inflation. But individual circumstances vary widely.

ALTHOUGH graduate employment prospects are improving rapidly from the doldrums of the early 1980s, many will still not find an easy or speedy transition from higher education into employment (*Nature* **310**, 260; 1984). With the government and its critics continuing to debate the likely level of future demand for places in the light of the declining numbers of 18-year-olds in the population, and with the apparent falling "rate of return" to studying many subjects in higher education, how attractive is the student grant in terms of supporting three years' investment in higher education?

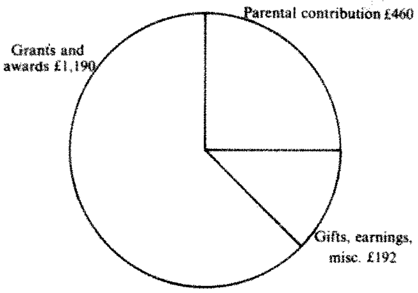

Fig. 1 Sources of student income for UK university and polytechnic students in 1982–83. (Source: NUS survey).

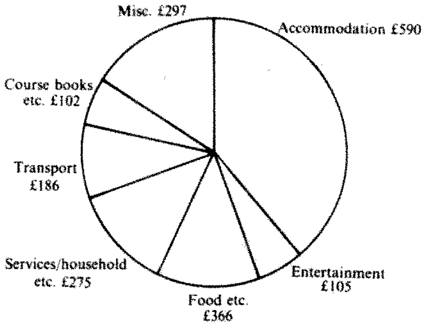

Fig. 2 Student expenditure for the academic year 1982–83. (Source: NUS survey).

In order to encourage student interest in subjects in demand by employers, the UK Department of Education and Science has announced that the amount undergraduates can receive from a sponsoring employer before their grant is affected will rise to £1,200 together with a £400 earnings allowance. For the lucky few who can combine sponsorship (see *Nature* **307**, 488; 1984) with a full grant, this means a student income of nearly £3,500 for the academic year, double the basic grant. A recent survey for the National Union of Students (*Undergraduate Income and Expenditure*, NUS, 1984) has, however, shown that for most students half this figure may be unattainable, with many parents not making up their means-tested contribution. Although the basic grant in 1982–83 was £1,595, the average student received only £1,167, and there has been growing concern about the adequacy of this grant whose value has fallen behind the inflation rate over the past few years.

In the United Kingdom, grants are payable to the majority of students on a means-tested basis; a student living away from home at a college outside London in 1982–83 could have received a maximum grant of £1,595 plus tuition fees from his local education authority. Various supplements are also payable, for example, to those studying in London, or on a course that is longer than normal , while mature students receive a full grant with no means test. One in eight students, however, received only the minimum grant payable of £410, some because they, or their parents, refused to take the means test, while a further 5 per cent received less than £600 because their parental income was too high. Half received under £1,200 and only one in four students received the maximum grant. The total amount saved by the means test was estimated to be over £150 million in 1982–83 compared with a total public expenditure on grants of about £500 million. Just over half the parents paid their assessed contribution, a rather higher proportion than in 1974–75 when only just over a quarter did so. Interestingly almost as many parents paid more than the assessed contribution as paid less than the total due and the size of the sum due from parents did not seem to affect the likelihood of the student receiving more or less than that assessed. In terms of basic grant, science and social science students got slightly higher amounts than the engineers and arts students. Average income for the academic year, including additions such as gifts and term-time earnings was £1,842, two thirds coming from the basic grant (Fig. 1).

A significant additional source of student income, outside term time, was vacation jobs, which gave an average income of £251 per student, with 10 per cent earning in excess of £700, and a few earning over £200 per week, although nearly half had no vacation job. By contrast ten years earlier 80 per cent of students had vacation jobs in the summer. Men received rather higher vacation income than women, while engineers and technology students received significantly more than the average, aided by sponsorship and enhanced prospects of vacation work. This latter factor also boosted term-time incomes of these students. Supplementary benefit and vacation grants were further sources of income out of term time for a minority of students, the average sum overall being around £100 per student.

Where then does the money go? Accommodation is the biggest outgoing. Only one in ten undergraduates in the United Kingdom lives in the parental home, while nearly half live in "official" college halls or hostels. College premises are particularly important for university students while for those at polytechnics, rented flats were the most common form of accommodation. In London, more students live in their parents' home because of easier travel conditions and larger college catchment areas and the lower availability of halls of residence. The average cost of college accommodation was £24 per week, with the polytechnics cheaper than the universities, most college accommodation including some food and services. Those in private rented accommodation paid an average of £14 per week each for rent alone.

Other living costs included food and household expenses, travel and recreational. Course-related expenditure included books and course equipment; average annual expenditure was to be around £100 with university students spending most (Fig. 2) and 10 per cent apparently spending nothing at all on books. On a subject basis, medical students spent most on course equipment with social science and language students also spending above the average.

The study showed that the majority of students relied on parental support or supplementary income to support part of their studies. While for the "average" student such supplementary income was usually forthcoming, some receiving more than the notionally required sum, many had to restrict expenditure significantly to sustain themselves. The survey, by revealing the many sources of income and grants available and the various patterns of expenditure, highlights the complexities of an informed debate about student finance. Perhaps the one clear message that comes through is that to plan grants, loans and finance around a notional average case will lead to very different outcomes for different individuals. Student finance is not an exact science. ☐

Richard Pearson is at the Institute of Manpower Studies, Mantell Building, University of Sussex, Brighton BN1 9RF, UK.

Past defended, future unforeseen

British higher education is once more under scrutiny. Both sectors of the binary system have now made claims and the government will soon decide. But constitutional questions are still begging.

THE elementary principle that he who pays the piper calls the tune is often nullified because the paymasters do not know what they would like to hear, which is why they often find it necessary to pay not just a piper but on pipe-music. This part of the reason why, in the administration of British higher education (and of that in many other parts of the world), relations between central government and the publicly supported universities are channelled through some intermediary — in the British case, the organisation called ther University Grants Committee. Some of the troubles that now afflict the British system of higher education have arisen because the present British Government differs from many of its predecessors in knowing — or in believing that it knows — what the system of higher education should be doing. For close on five years, the paymaster has been pipe-master as well, with disastrous consequences. By the end of this year, with the appearance of the promised reappraisal of policy, it should be clear whether there is now to be a return to normalcy and good sense.

In normal times, last week's argument by the University Grants Committee (see page 196) would have been taken as a sign that the future must now be brighter than it has seemed. The committee has put forward a case that is at once cogent and combative. It is on sure ground in pointing to the errors in the calculations by the government (and others) of the way in which the demand for student places will decline, for demographic reasons, in the years ahead. It is right to protest that if the present system and further planned reductions of expenditure continue, the university system will not be able to adapt without structural damage, certainly to the quality of institutions, perhaps to the survival of some of them. The committee is also on firm ground in arguing for some means of rejuvenating the teaching staffs of British universities, asking that at least 3.5 per cent of academics should be replaced each year, if necessary by the continuation of schemes for persuading older people to retire early. All these proposals will make eminent sense to British academics, who will recognize that they again have an intelligent and robust friend at court. This is precisely what would have been expected from Sir Peter Swinnerton-Dyer, the committee's chairman for only the past year.

Dissension

On the committee's long list of practical proposals for change, there are several that should not cause dissension even in its relations with the government. Most obviously, it is hard to see how the present British Government, which is forever urging that the universities should raise a greater share of their income from other than public sources, can continue to resist reforms that would simplify that task. The notion that gifts by corporations to British universities should be tax-free only if they can be shown to further the donor's corporate interests (the present position) is absurd, and should be abandoned promptly. The present tax regulation that allows no relief from personal taxation in respect of the payment of fees for higher education is both a restraint on the ability of universities and other institutions to attract students and a foolish fiscal economy when the need for added skill is as great as even the government acknowledges it to be. The way in which the British Treasury is empowered to play a game of cat and mouse with supposedly autonomous universities wishing to dispose of physical assets, and which cannot know in advance what proportion of the proceeds they will be able to keep for new development and reorganization, is both inequitable and an encouragement of sloth. The general suspicion that institutions that succeed in raising outside funds, perhaps by benefactions, will then get less from public funds, which the committee says is not the case, should be formally denied by the government which has helped to create this false impression. It will be discreditable if a government that has been preaching self-reliance for the universities for the past five years cannot meet this reasonable demand by the grants committee. That is the small change of what the committee asks on the universities' behalf.

Trouble

The bigger questions will not be answered as readily, as the grants committee must know full well. The issue of who shall become a student, for example, is certain to cause trouble. Pointing out that the government has made elementary errors in its calculations of changing demographic patterns of demand is bad enough, which no doubt is why the grants committee has not taken the obvious further step of reminding it that many of the economies decreed in higher education in the past five years have been literally a waste of resources — academics have been tempted into not teaching students seeking higher education by an early retirement scheme that will have to be paid for out of future budgets. What the committee has done, in concert with the National Advisory Body, is to rewrite the standard criterion for telling whether a would-be student should be eligible for a place at a university or polytechnic. Liberally, the committee holds that the words "qualified by ability and attainment" are too obvious an invitation to over-specialization in the preparation of school-leaving examinations, and too discriminatory against those who would come to higher education later in their careers. The snag is that the alternative form of words now put forward — "able to benefit" — will seem to the government to be a demand for a blank cheque. And the demand will easily be denied. The government will merely have to repeat what it has creditably said of high-school education about the importance of objective as distinct from relative measurements of attainment. It need not confess that its real anxiety is that open access, or access determined by other people's assessment of who would benefit, will in principle bring into play the government's obligation to pay students a pittance of a salary (called a maintenance grant).

The grants committee's proposals on academic staffs at British universities are similarly vulnerable to government obtuseness. If it is asserted that younger academics are in some sense more desirable than older experienced teachers, why (the government will ask) should older people generally speaking be better paid? The grants committee, unfortunately, cannot put into words what it knows to be the truth, that even the most careful assessment of people's quality at the outset of their careers cannot predetermine excellence, and that what it wishes to do is to operate an informal and unspoken system whereby academics can generously be put out to grass at widely different stages in their personal development. The case for that is strong, and equitable in spite of the appearances. But the British Government, and even the academic professions, are unlikely to accept it in its unvarnished form. A guileful statement of the case would have been barely saleable if the grants committee had been able to suggest a compromise with the government on academic tenure, but the best it has been able to muster is a proposal that probationary periods should last for five years, not three. The committee's reminder that universities individually are always free to dismiss academics whose work is less than satisfactory will not satisfy a government persuaded that academic tenure is a charter for wrong-thinking layabouts.

The committee's arguments on research are similarly ambiguous. It is right to say that British universities are responsible for well over half of British basic research. It could have claimed the more interesting half. But it will cut very little ice with a sceptical government that, having accepted the universities' view that money should not be allocated separately for teaching and research, the committee should not be able to say how it will "be more selective" without further consultation. Worse still, the committee has to confess that its efforts will not succeed unless universities themselves become more self-conscious about their prosecution of research.

Much the same is true of the committee's case for extra funds within the university system. The case is overwhelming when the need for industrial change has become as clamant as in Britain now, yet outwardly the universities' case is little different from that of other claimants on the public purse. The coalminers of Britain, for example, are flush with arguments about the strategic importance of stable mining communities. The best hope for the immediate future is that the government may listen to what the grants committee has been saying for long enough to provide a chance for internal change to be engendered. The danger is that the government will lose patience.

The most serious gap, and thus the most serious weakness, of the universities' claim on the British Government is that the committee has so little to say on their behalf about their constitution, and about relationships between the public and private sectors. Yet the greatest iniquities of the past few years are embodied in the ways in which universities have been told how many students they may teach and are now being moulded on patterns specified from without. Academics apparently willing to go to the stake in defence of academic freedom supposedly bound up in the rules of tenure seem much less eager to defend their institutions on these more important counts. The only remedy is that constitutional autonomy should be backed by financial autonomy, and that academic institutions — public as well as private — should be allowed to make their way in the world by the reputations they are able to acquire in the eyes of students and students' employers. If, in the arrangement of financial autonomy for universities (and polytechnics), it were possible also to solve the government's problem of the blank cheque — the fear that more students must mean extra maintenance costs — it might be possible to look forward in Britain to a system of higher education that would change to meet external needs without external prodding, and which would be free from the attributes of academic class-distinction that now compromise the good work that individual institutions do.

In due course, the grants committee and its opposite number for the public sector will come to recognize that such a solution is inevitable. So, too, will the government. For the time being, however, the best that can be hoped for is that higher educational institutions, public as well as private, will recognize the potential value of diversity and their masters the importance of autonomy. The grants committee's document refers to a scheme the British Government was canvassing earlier this year that would have given some universities a fixed budget, no other marching orders but an exhortation to make what they could of their resources. Cryptically, the committee says it will give its opinion on the scheme "if asked". Appearances to the contrary, its opinion should be that everybody would stand to gain from an experiment in autonomy along lines like these. Why not offer an opportunity for one university and one polytechnic to try their hands at freedom within the confines of an inflation-proofed public subvention? Or is everybody afraid of being overwhelmed by the rush of applicants? ☐

Help for Argentina?

The plight of Argentinian science (see page 201) deserves widely to be recognized.

IT is easy for those in developed countries to regard the sorry state of Argentinian science with the contempt familiarly accorded the efforts of developing countries to appear scientifically sophisticated; building biotechnology centres without biotechnologists to populate them, or research reactors when there are no nuclear physicists. But Argentina is different. It has produced a large number of first-rate scientists (many of whom now work in the United States or Europe) and it has made a not unrespectable start at industrialization, helped by near self-sufficiency in petroleum and a major surplus in agricultural products. Argentina is not a banana republic — indeed, until December of last year, it was not even a republic. And that is crucial to understanding the special nature of Argentinian science, and why it is in a different mess from that of other developing countries.

In addition to its major credentials of repression, murder and the Falklands war, the military regime that seized power in 1976 can claim credit for the dismantling of Argentina's scientific institutions, the universities in particular. The potential remains, but its realization is further away than ever. The return to democracy, still a source of wonder and justifiable admiration in the Western world, has brought with it a sweeping change of attitudes. Some of the most competent and knowledgeable people one could expect to find in any government have been put in charge of repairing Argentine science, but the task requires more than clear thinking. It is difficult to have a science policy without money, and Argentina has none. And the new government will not indulge the luxury of investing long-term in science and higher education while its overseas debt amounts to $50,000 million — and while it has to keep borrowing more to pay the outstanding interest.

So what can others do to help? And why should they bother? External financial aid for scientific institutions would be invaluable, but is unlikely to materialize quickly. Yet that is no reason why the question should not be considered. In the past few days, the World Bank has made a loan of $25 million to the People's Republic of China to help with the foundation of a network of institutes for agricultural research. Even allowing for the way in which China has become the apple of Western eyes, and for the fact that Argentina still has to meet the tough monetary conditions prescribed by the World Bank's sister organization, the International Monetary Fund, the case for a special loan is powerful.

The extent of the damage done to Argentinian science — and the real potential for excellence — has magnified the value of more informal contributions. People in the United States and Europe will do far more than they can perhaps imagine possible for restoring science in Argentina simply by participating in conferences there, by spending time there as visiting professors or teaching short courses, or simply by keeping in contact with Argentinian scientists who have been isolated by the recent events, and who face enormous difficulties in what is elsewhere the effortless task of keeping up with current scientific information. The shortage of foreign journals, always a problem in developing countries, has been greatly exacerbated by the military regime's policy of choking off the universities.

To those in Britain who may mumble about the Falklands war and about cooperation with a nation still technically at war, it is worth noting that the best assurance of peace and reasonableness on all sides is the presence of a democracy in Argentina. It was a desparate totalitarian regime that launched the Falklands war, an awkward legacy for the new government. And at least among educated Argentinians, one is more likely to hear joking references to Britain's "enemy" status than talk of vengeance. Anything that can be done to bolster Argentina's democracy, and its commitment under President Raul Alfonsin to make education, rather than weapons, the foundation of its national security, is a step in the right direction for everyone concerned. ☐

Restraints on publication

Deal in prospect on US export rules

Washington

A WORKING group headed by the President's Office of Science and Technology Policy has recommended that draft export control regulations be altered to provide greater freedom for scientific communications. This was announced by Charles Herz, general counsel of the National Science Foundation and a member of the group, speaking at a meeting of the Department of Defense-University Forum last week. The forum had made several specific suggestions to the Department of Commerce, the agency charged with writing the regulations, chief among them being the idea that fundamental research should be controlled only through national security classification and not through any rules requiring universities to obtain an export licence before publishing research results.

The group also recommended that when export controls are applied to university research, research contracts — rather than licensing procedures — should be the enforcement mechanism. The point is an important one to universities, which have demanded to know in advance of accepting research contracts whether their freedom to publish will be restricted. Many universities as a matter of policy refuse to accept such restrictions.

Under the working group's proposed changes, any research at universities that complies with contract terms would automatically be granted a "general licence" for "export" — a term which includes publication. The situation now is that universities in principle could find themselves in double jeopardy in that publication may be cleared by the Department of Defense (DOD), but still be held a violation of export rules by the Department of Commerce.

An earlier plan to establish a broad category of "sensitive" but unclassified research that could be subject to export controls was abandoned by DOD in May in the face of stiff university opposition. DOD's revised policy exempts "fundamental" research from controls.

But questions remain over just how DOD and the other federal agencies plan to apply export controls to publication other than fundamental research. David Wilson, the universities' co-chairman of the DOD-University Forum committee on export controls, recommended that export controls incorporated in research contracts should permit DOD only a 60-day review before publication. DOD could then advise the university of information in the proposed publication that would violate the export act if published, but the ultimate decision whether or not to publish would remain with the university.

The definition of "fundamental" research remains unclear. DOD officials and Wilson seem to agree that a reasonable approach would be to define as fundamental on-campus research in what DOD calls categories 6.1 or 6.2, which correspond to basic research and "advanced technology development" respectively. More than 99 per cent of on-campus research supported by DOD is said to fall in these two categories, while the remainder is in category 6.3, "strategic programmes". That, as well as 6.2 research conducted at off-campus facilities such as Johns Hopkins University's Applied Physics Laboratory, could be subject to contract restrictions based on export control authority. (An exception is to be made for star wars research which, although categorized as 6.3, will for the most part be considered fundamental.)

DOD officials say they need the "flexibility" to apply restrictions to sensitive research that does not warrant classification, which they say is "a pain in the neck", because classified documents are subject to security restrictions — they must be kept in locked cabinets, for example, and cannot leave offices or be left lying on desks.

Stephen Budiansky

● Meanwhile, a revised Export Administration Act — needed to implement the regulations — remains stalled in Congress. At a conference committee meeting last week, House members refused to accept compromises offered by the Senate on contract sanctity and national security. More meetings are planned this week. The commerce department, however, has shifted its position on high-technology exports of equipment (as opposed to information). Its latest proposals would allow the exporting companies themselves to enforce the regulations, subject to audit by the departments. □

AIDS

Virus clones multiply

Washington

YET another US genetic engineering company has jumped on the bandwagon of acquired immune deficiency syndrome (AIDS). The Chiron Corporation, of Emeryville, California, announced last week that its researchers had succeeded in cloning the entire genome of a putative AIDS virus isolated by Dr Jay Levy of the University of California at San Francisco. Earlier this year, Chiron was not among those companies selected by the federal government to develop a diagnostic blood test for AIDS from virus isolated at the National Institutes of Health by Dr Robert Gallo.

Following the frequent practice of some genetic engineering companies, Chiron made its announcement without at the same time publishing details of its accomplishment. Lacey Overby, a vice-president of Chiron, said that a scientific manuscript describing the process was essentially complete and ready to be submitted for publication. Overby averred that scientific journals seemed not to mind publishing previously announced findings. Chiron plans to work on expressing the viral proteins in yeast cells, a field in which it already has expertise.

Chiron says it assumes that the virus isolate it is using is the same as the human T-cell leukaemia virus III isolated by Gallo. The cloning of the virus paves the way for a widely available diagnostic test that does not require the intact virus to be used, as well as, perhaps, a vaccine.

But Chiron is not alone in the race to produce an AIDS diagnostic nor the first to have cloned an AIDS-linked virus. Gallo has also now cloned his viral isolate, and probably others have done the same without making an announcement.

Chiron says its public statement is justified by the "intense competition" in the field. Chiron expects to be making a profit within the next 18 months (it was incorporated only in 1981) and reports that clinical trials on what is likely to be its first commercially available product, a genetically engineered hepatitis B vaccine, are going well.

Tim Beardsley

Entrance standards on increase

BRITISH universities are demanding higher examination grades from prospective students than they did in 1980. This conclusion can be drawn from Universities Central Council on Admissions (UCCA) statistics recently released. Entrance requirements for each of the 24 main university subjects have risen with those for electrical engineering and computer sciences showing the most marked rise.

UCCA believes that the increasingly high standards required for university entrance are deterring marginal candidates — those who may not have attended good secondary schools but might, nevertheless thrive at university — from applying. The statistics also show that young people from wealthier families are still over-represented among successful applicants.

Marcus Chown

British universities

Champion springs to life

THE University Grants Committee (UGC) has told the British Government that, on present financial policies, it may be necessary for one or more universities to be closed. And UGC goes on to say, in its document *Strategy for Higher Education in the 1990s*, published last week, that it will leave to the government the invidious choice of institutions to be shut, on the grounds that it is not itself competent to assess non-academic considerations and that, in any case, its relationship with universities generally "would not survive" the act of pointing the fatal finger.

UGC's document, like the parallel document also published last week by the National Advisory Body (NAB, responsible for non-university higher education, especially the polytechnics), is formally a response to a government request for advice in advance of the reappraisal of higher education strategy, advertised for later in the year.

UGC's gloomy forecast arises from its calculation that published estimates of spending on higher education in the years to 1986–87 entail an annual reduction of 0.5 per cent, and from experience in recent years that university pay settlements have exceeded the amount allowed for to an extent that will impoverish the universities by a further 1 per cent a year. Tartly, UGC says that universities conformed more closely to the guidelines on public sector pay than government itself.

UGC's gloomy forecast stems partly from its view that the budget cuts of 1981 have already forced universities to mortgage their "freedom of manoeuvre", and that further cuts will require commensurate staff reductions. Faced with that need, UGC says, it would prefer to recommend contraction on a discriminatory basis rather than letting the cuts fall equally across universities. But that course could prove impossible, in which case it would be forced to recommend "with extreme reluctance" that some universities should be shut.

UGC adds that it cannot understand the implications of such a development, for the institutions closed would probably have "better" students, staff and facilities than "most institutions in the public sector", and says that closing a university would entail a waste of assets that "could not be defended".

For the years ahead, what UGC pleads for is "level funding" at the very least. As things are, its document argues, shrinking budgets will mean that fewer students can be taught. Stability, on the other hand, could mean that universities could provide more education for the same cost.

Even level funding will not, however, allow British universities to finance a substantial increase in the number of student places in science and technology, an expansion of continuing education and the rejuvenation of university teaching staffs by the replacement of older people by newer recruits. And the strategy document makes a strong case for each objective, the first of which at least is that of the British Government as well.

Both UGC and NAB also quarrel with earlier government estimates of student demand over the remainder of the century. UGC argues for an increase (to 170,000 a year) in the number of British students entering full-time education, and for a total full-time student population of 600,000 by the end of the decade. UGC asks that, when the British Government finally picks a number, there should be consultation on the distribution of students between "private" and "public" sectors.

NAB is more bullish, largely on the basis of a redefinition of the criteria for access to higher education agreed with UGC, that higher education should be open to "those able to benefit" from it, and who wish to do so. As things are, the guiding principle, laid down in 1963, is that students should be "qualified by ability and attainment".

UGC includes a discussion of the statistical errors of earlier estimates of student demand, and asks that the basic data should be refined before estimates are calculated for the 1990s, saying that demand will not diminish "just because there are fewer 18 year olds". It fears that there will be shortages of graduates "across the board" as "the country moves out of recession".

On government pleas for a "switch" from the arts and humanities to science and technology, UGC argues that the pace of change will be determined by the "supply of good students", saying that the problem would be transformed if more "girls" (*sic*) could be persuaded to "develop an interest in mathematics and physical sciences". UGC says that extra funds would in any case be necessary, and that extra science places at universities should not be provided at the expense of the arts and humanities.

On research, UGC says that it proposes to accept the general university opinion that individual budgets should not deal separately with teaching and research, although it accepts that universities deserve a fuller account of how their budgets are determined. The document says UGC will be "more selective" in favour of strong research universities, but only after further consultation. UGC adds that its policy will succeed only if universities equip themselves to decide strategies on research.

By its tone and in what it says, the UGC document should help restore UGC's reputation among academics as their defence against the government. Whether the latest defence will prove sufficient remains to be seen. □

French research

Growth rate is checked

Paris

THE French research budget for 1985, published last week, is good. But not so good as last year, or the year before. Research spending in France, previously buoyant, is reaching the top of the S-curve. At the same time, some of the more ambitious ministerial efforts at linking French research with industry are now deemed failures. Science policy-makers should reflect on how best to continue the French experiment of "solving the economic crisis through science".

In 1983, the first big year for science in the Mitterrand presidency, the budget for fundamental research leapt by nearly 25 per cent in current francs, and applied research by 18 per cent, compared with a net government budget increase of 13 per cent. In 1984, as the recession began to bite, growth slowed to 12 per cent in fundamental research and the same in applied research, against a net government budget increase of 4 per cent (and 7 per cent inflation). This was not enough, researchers began to complain, to cope with the franc falling rapidly against the dollar and other currencies in which materials and equipment are usually purchased. (The franc has fallen 25 per cent even against the pound since 1982.)

This year, increases will be less again (but at least they are increases). Fundamental and applied research should each grow by 10 per cent against the net budget growth of 3 per cent and projected inflation of 4.5 per cent in 1985, research minister Hubert Curien announced last week.

CNRS, the principal research council for basic science in France, will see an increase of nearly 8 per cent in its operating budget next year. This, however, will be fully taken up, says director Pierre Papon, by existing CNRS expansion programmes in microelectronics — a new major laboratory is planned at Bajneux to the south of Paris — and other areas.

Yet Papon is pleased by the new posts offered by Curien. The minister will create 536 new posts for fundamental researchers, of which 300 will go to CNRS. Combined with vacancies arising from departures and retirements, CNRS will have 500 posts, around 5 per cent of its total research staff, to play with this year. This gives some real room for policy-making, Papon says, allowing for expansion in priority areas (life science, engineering and social science) and even in some "second order" priorities (such as high-energy physics, which will be favoured over low-energy nuclear physics next year).

Linking researchers with French industry remains one of Curien's highest priorities, but the more centralist exercises of the ex-research minister Jean-Pierre

Chemical Engineering
Chemical Technology
Plastics and Rubber Technology

Chevènement are now being described by policy-makers as "70 per cent failures". These were "*programmes mobilisateurs*" designed to stimulate action in fields like bio-technology and information technology. The problem: the French penchant for autocracy. The *programmes mobilisateurs* were to be run at arm's length by small groups at the Ministry of Research (responsive to the needs of industry and research). But these small groups grew too large, and developed ideas and programmes of their own. Industry saw them as socialist interventionalism. Papon himself admits he is anxious.

Meanwhile, Curien hopes to respond next year with a new and somewhat wiser "law for research" — wiser indeed than the Chevènement version of 1982, which aimed at an increase in French national research and development spending from 1.8 per cent of gross national product in 1981 to 2.5 per cent by 1985. That will not be reached, but the ratio will be 2.8 per cent. Now France is waiting for industry to respond.

Robert Walgate

Merger resisted

Düsseldorf

THE Social-Democratic (SPD) Government of Nordrhein-Westfalen in Düsseldorf has protested vigorously against the plans of the federal Minister for Research and Technology, the Christian Democratic (CDU) Dr Heinz Riesenhuber, who has proposed that the main thrust of biotechnology research in West Germany should be concentrated in future in one, rather than two, research centres.

Last year (see *Nature* 106, 305; 1983), an investigating committee suggested that the two major centres at Jülich (Nordrhein-Westfalen) and Braunschweig-Stöckheim (Niedersachsen, CDU government) would be better amalgated into one, thus improving the efficiency of research and reducing its cost. The new committee recommended that the new centre should be based in Braunschweig despite the committee's poor opinion of the standard of the work of the 350 research workers at Braunschweig, and its praise for the work of the 100 researchers at Jülich.

Rolf Krumsiek, Minister for Research in Nordrhein-Westfalen, has now promised to retain the Jülich institute at its present size, and in this he has the full support of the two directors of this research centre, Professor Hermann Sahm and Professor Christian Wandrey, both of whom wish to stay in Nordrhein-Westfalen. This difference of opinion between the central government and that of Nordrhein-Westfalen may bring difficulties should the central government decide to withdraw its financial support for Jülich, at present 90 per cent of the total cost. Retention of an interest in this promising research sector would then require an enormous financial intervention from the *Land* government.

Jürgen Neffe

European science

Forging stronger research links

Paris

THE European Science Foundation (ESF), a cooperative focus for over 50 national science funding agencies in Europe, has received broad political backing for a $1 million increase in its $2½ million budget — to help European researchers to keep in touch with one another.

This was one of the more concrete results of a unique meeting in Paris on Monday of 21 European research ministers under the auspices of the Council of Europe. The meeting, which had taken nearly a year of preparation, aimed at creating a "fresh political impetus" to European scientific co-operation, and this it has clearly done. However, although it recommended $1 million for ESF, the meeting had no power actually to define a budget. ESF must wait to see if its member agencies can find the cash.

Certainly, better cooperation as would be developed by ESF in a number of specified research areas is necessary, if any real life is to be given to the concept of "European research". The French Centre National de la Recherche Scientifique (CNRS), for example, annually sends more scientists to California than it does to the whole of Europe put together. And CNRS is not alone, either in its Atlanticism or in the need it feels to balance this by increasing cooperation within Europe.

In Paris on Monday, ESF was recommended to create "networks" of exchange in, for example, oceanography, Earth sciences, materials sciences, epidemiology and, altogether, 18 other fields of research. Although the money required would be a considerable sum for ESF, it would be small in relation to total European research budgets (a "per cent of a per cent", says ESF).

Now, ESF will make a detailed study of the 18 network proposals, themselves already filtered by ESF from around 200 originally received from national bodies before the conference. ESF will make specific recommendations for action within five months. The networks would differ from the superficially similar stimulation programme of the European Economic Community in one important respect, said ESF vice-president Professor Roger van Lieshout: they would be aimed at individual scientists, offering them mobility and choice, rather than at specific institutions. "If you create a centre of excellence, it will always remain a centre but not always remain excellent", said van Lieshout.

Also on Monday, the Council of Europe was instructed to consider the introduction of a "researcher's card". The card would be a kind of passport to Europe allowing accredited researchers certain privileges (such as help in getting electronic equipment past inquisitive customs officers). The Council of Europe should also consider, said the ministers, other moves to improve mobility by removing certain trivial but cumulatively important obstacles to free exchange — such as freedom to open a bank account.

Peter Brooke, the British research minister, also made a surprising and last minute proposal: to create a prestigious European academy like, for example, the Royal Society and the US National Academy of Sciences. This would foster a sense of identity among European scientists, said Brooke. Conference president, Frenchman Hubert Curien, described the proposal as "very interesting", but it was not among the official recommendations of the meeting. Britain may take the proposal further on its own initiative, said Brooke after the meeting.

Robert Walgate

Amazon to yield more secrets?

THE government of Brazil has invited a team of Soviet oceanologists to carry out a survey of the Amazon and its estuary. This is a follow-up to last year's expedition aboard the Soviet oceanological research vessel, *Professor Shtokman*, in February–April 1983, in which a joint Soviet-Brazilian scientific team took part and which penetrated far up the Amazon as well as surveying the ocean around its outfall.

The 1983 expedition concentrated on the geological sampling of the bed, ichthyological studies, and also some hydrographic work. The exceptional depth of the Amazon (as much as 100 m in places) — a consequence of the river lying on the boundary of two geological plates — made it necessary to use an ocean-going vessel. Much of the data from the 1983 expedition remains to be fully worked out. Nevertheless, according to Academician Aleksandr Yanshin, a vice-president of the Soviet Academy of Sciences, much has already been discovered.

Numerical data from the 1983 expedition include figures for the annual outflow of the Amazon (6,000 km^3, some 50 per cent more than the total of all Soviet rivers apparently) and the annual sediment burden (300 million tonnes). Theories have been developed to explain how the sediments became spread out all along the coast of South America rather than forming a delta as with most major rivers.

One notable discovery, the Soviet hydrobiologists claim, was that the Amazonian river water retains its brown colour even after the precipitation of all sediments. This, it is thought, is due to the presence of dissolved organic compounds, reminiscent of swamp water.

Vera Rich

Patent rights

Patient sues for title to own cells

Los Angeles

A FORMER leukaemia patient last week sued doctors at the University of California, Los Angeles (UCLA), for patenting and marketing a cell line derived from his spleen, removed to save his life. The suit, said to be the first of its kind, raises the ethical question of who has the right to profit from biological discoveries made by physicians using patients' organs.

The cell line, named "Mo" after patient John Moore, has potential commercial value in treating or perhaps even curing blood diseases including cancer and acquired immune deficiency syndrome (AIDS), according to Mr Moore and his Beverly Hills attorney, Sanford Gage.

In the lawsuit, filed in Los Angeles Superior Court on 11 September, Mr Moore asserts his ownership of his blood and bodily substances and of any by-products produced from them. The University of California patented the cell line without his permission, he says, but could conceivably make millions of dollars from it.

The UCLA researchers, Dr David W. Golde (chief of haematology and oncology) and medical technician Shirley Quan, say, however, that the cell line has not proved to have any commercial value, even though it is an "enormously valuable research tool". For example, Mo is the cell line which provided the supernatant from which Dr Robert Gallo of the National Cancer Institute isolated a human T-cell lymphotrophic virus, called HTLV-II. This virus, which is rare, evidently caused Mr Moore's disease, a T-cell variant of hairy cell leukaemia. A similar virus isolated in 1980 from other cell lines, called HTLV-I, is recognized as the cause of adult T-cell leukaemia, while HTLV-III, discovered in recent months, is the cause of AIDS.

...and Mr Doe reserves full rights to his tumour...
CONTRACT
ATTORNEY
BIRCH

The potential commercial value of the Mo cell line lies in its unusual lymphokine activity. Lymphokines are hormone-like substances secreted by lymphocytes with wide-ranging biological activity. They act locally to modulate cells responsive to them. They include interleukin-2, colony-stimulating factor, neutrophil migration inhibition factor and an erythroid-potentiating protein.

Mr Moore's spleen cells provide an unusually rich source of these proteins, which is why the University of California took out a patent, granted in March 1984, on the line. When the patent was applied for in 1976, there was growing commercial interest in producing interferon as an antiviral agent.

There are now nearly one hundred other cell lines, many of them not patented, which are also rich lymphokine sources. Lymphokines are still defined phenomenologically, and their potential in treating viral diseases is still highly speculative. But according to Dr Golde and others, Mr Moore's spleen cell line and his blood serum are still especially interesting because of the rarity of his leukaemia and the virus that caused it. **Sandra Blakeslee**

- The question of availability of the Mo T-lymphoblast cell line has caused some controversy. The complexities of the situation were touched upon by Dr Golde (*Nature* **308**, 19; 1984), responding to the various requests for the cells. He explains that the cells would become available from the American Type Tissue Culture Collection when UCLA's application for a patent had been processed. Those wanting the B-lymphoblasts from patient Mo, however, are not, it seems, affected by the patent. ☐

US pharmaceuticals

Patents extended, generics agreed

Washington

A DEFT legislative compromise appears to have pleased both research-based and "generic" pharmaceutical manufacturers in the United States. The two houses of Congress last week agreed on a bill that will extend the lives of patents on new drugs to compensate for the years spent by their manufacturers in seeking regulatory approval. Manufacturers of generic drugs have also won, in that they will in future be able to rely on the original testing data of a drug to back applications to market a generic equivalent once the patent term has expired. The Drug Price Competition and Patent Term Restoration Act, as it will be known, is backed by the administration and is likely to be signed into law within the next few weeks.

The research-based drug companies, represented by the Pharmaceutical Manufacturers Association, have long argued that the lengthy process of obtaining approval for a drug from the Food and Drug Administration (FDA) seriously reduces the incentive to search for new therapeutic compounds. In 1983, according to the association, each new drug brought to the market had soaked up an average of $91 million in direct and indirect costs, typically over 7 to 10 years. Only one in three drugs provides a reasonable return on this investment, and by the time all regulatory hurdles have been cleared, on average only 9 years of patent life remain out of the total of 17 years.

The new bill will allow an extension of the patent term by up to 5 years, with the proviso that the total remaining patent life after extension cannot exceed 14 years. The extension comprises one half of all the time the company spends testing, plus all the time the FDA spends processing applications. The special needs of genetic engineering companies are recognized in the bill: though normally there can be no more than one patent term extension for each product, substances made by recombinant DNA technology are treated for this purpose as if they differ from the same substance made by conventional means.

On the other side of the coin, generic brand manufacturers can often sell their products at very much lower prices than the original versions. These manufacturers argue that the public interest is best served by maximizing competition, but they also complain that, as things stand, they are caught in a "paperchase" when seeking regulatory approval for their products. Although, in principle, generic manufacturers may support their applications with data from previous tests on the same substance, the original data are often not published in the open literature, and many tests have to be repeated.

The new act introduces an "abbreviated new drug application" (ANDA) which simply requires the generic manufacturer to show that a product is essentially identical with an existing approved drug in terms of dosage and bioavailability. Senator Orrin Hatch (Republican, Utah), who sponsored the bill, quotes $1,000 million as the likely savings by consumers over the next 10 years as more generic drugs become available, although more cautious observers say it is impossible to make estimates of this kind.

The wheeling and dealing that went into the bill has led to an unusually complex set of rules on when ANDAs may be filed. An earlier version caused serious divisions within the Pharmaceutical Manufacturers Association because it would have allowed a generic drug manufacturer to obtain approval for a copied drug only 18 months after challenging the validity of a patent covering the product. The result could have been that research-based manufacturers would have had repeatedly to defend themselves against patent challenges. In the final version of the bill, ANDAs linked to patent challenges may be submitted to FDA 4 years after approval of an original drug, though marketing approval for the generic version must wait 7½ years from the original approval. **Tim Beardsley**

British Association for the Advancement of Science — Norwich

Accountability and the future

SIR Hans Kornberg's new blue-and-white insignia, whose glorious silver pendant marks him as next year's president of the British Association for the Advancement of Science, match his pyjamas. So, with glee, Sir Hans revealed to his neighbours at the British Association (BA) "science audit" last Friday. The pyjamas were not, however, on display.

The other delights at the University of East Anglia (Norwich) last week included a "Santa Claus machine", and the founder of the Open University proposing a £400,000 experiment to simulate a Martian colony on Earth and a delegation from China. There were also scientific submeetings galore, prizes, reviews of oncogenes and opiates, the first of Richard Gregory's exploratorium experiments, accounts of the environmental rape of the developing world and the terrors of future war. . . .

Fie to figures

AT least one industry in Britain will be booming next year — the industry of research on research. The beginnings of the industry were on display at Norwich in the BA audit of science spending and in the forthcoming Annual Review of Research by the Cabinet Office, introduced by cabinet science advisor, Robin Nicholson.

Nicholson's figures were preliminary: a collation of departmental projections. But they confirm that there will be a real reduction of a few per cent in the British Government's science spending in the next few years. Sir Bruce Williams, director of the Technical Change Centre (whose researcher Ted Butler was lent to the BA for the audit) found Nicholson's figures "very disturbing". He was also disturbed by the present scale of British civil research and development spending which, when measured per capita, begins to look "very small indeed" (half that of Switzerland, two-thirds of West Germany).

The BA audit also shows that Britain's military spending, usually taken to be half the British research and development effort, is "considerably overstated". As for the universities, a little embarrassment could be detected at Norwich. The figures on university research revealed by the audit show reductions since 1980 "nowhere near as severe" (said Sir Bruce) as had been claimed earlier by the Advisory Board for the Research Councils (ABRC). In the fifteen years up to 1981, funds for British university research (including salaries) doubled in real buying power. From 1964 to 1983, university research and development rose from six per cent to ten per cent of total British research and development. (But the real resources of the research councils were static between 1976 and 1980, and fell about five per cent in the next three years.)

After that doubling, is there not dead wood to prune? Sir Keith Joseph, Secretary of State for Education and Science, keeps asking that. Research chums together, as at Norwich, know there is more to it than that; the doubling has been needed "to stand still", to keep up with techniques and instrumentation and to pay for entry into new branches of research. These costs could not have been covered by pruning old branches, said Sir Bruce. But yes, there is dead wood, admitted Sir Geoffrey Allen (ex-chairman of the Science and Engineering Research Council), chairman of the BA science audit for a second year.

The perception in the community is that things are much worse than the figures show.But there seems a dawning realization that university researchers must explain themselves more clearly. And it should be a major impetus for more research on research.

The Technical Change Centre would like to help with that, Sir Bruce Williams says, but its funds are limited. But Nicholson was more forthcoming; perhaps £250,000 a year would suffice in the medium term. The ABRC could find the money "within the errors" of counting the science budget, he said.

Taking measures

HOW to measure science? Notoriously, it is much easier to measure inputs (money) than outputs (science). But now ABRC chairman Sir David Phillips has been converted to the measurement of scientific output by citation indices suitably modified by interviews, peer ranking and other indicators.

Where from this light on the road to Damascus? The Science Policy Research Unit (SPRU) of the University of Sussex, where two social science renegades have charmed Sir David with their analysis of research in protein crystallography (his own field). Sir David has prodded the Royal Society to head a pilot study of the health of British science using the SPRU techniques. With £25,000 from ABRC and £15,000 from the Economic and Social Research Council, whose chairman Sir Douglas Hague is also a convert, the Royal Society is to assess the productivity of British geneticists, solid state physicists and chemists.

The two renegades now brought in from the cold are Ben Martin and John Irvine (who recently reviewed the work of the European centre for nuclear research, CERN — see *Nature* 6 September, p. 4). Royal Society officials were visiting them last week.

"Martin and Irvine", names that will soon be as familiarly linked as "Laurel and Hardy" in British science policy, first shook the world with a citation and peer-review attack on the Jodrell Bank radio telescope at Manchester.

Future-watching

ONE of the more playful themes at Norwich was 2010, or 2050, or whatever: the distant future. There were plenty of predictions: a chip with numbers of components to match the number of neurones in the human brain by 2000 (Brian Oakley, director of Britain's information technology programme) and NATO (the North Atlantic Treaty Organization) turning from defence to offence in Europe in the next few years (Frank Barnaby, peace researcher). Barnaby said the future has lost its flavour because everybody is concentrating on getting through 1984 or 1985.

It was different 20 years ago, when broadcaster Nigel Calder was editor of the popular science magazine, *New Scientist*. He asked scientists to predict 20 years ahead (George Orwell's 1984) and, said Calder, on the whole they got it right. Nevertheless Werner von Braun erred on the optimistic side (nuclear-powered rockets and men on Mars) as did hovercraft inventor Christopher Cockerell (hovercraft everywhere). Others foresaw home video-recorders, optical cables and the new biotechnology.

What of our future now? Calder listed a few machines — the total information machine (everything accessible with a chip) and the Big Brother machine (total surveillance). A little further off may be the Santa Claus machine, "a large, self-governing device that eats rocks and excretes anything that human beings care to specify: coffee cups, Porsche cars, spaceships, or other Santa Claus machines".

Colonies on Mars

LORD Young (Michael Young) is also worried about the future. But he has plans. Founder of the Consumers' Association (publisher of *Which?*) and the Open University, he now aims to found something out of this world: a colony on Mars. He says it should be the goal of the European Space Agency and that, though a century or so off, the prospect of a Martian colony could raise the sights of mankind above our petty squabbles.

Meanwhile Lord Young is seeking £400,000 to build two domes. One dome would have a simulated Martian desert, permafrost and landscape to test the theory of atmospheric chemist James Lovelock that an injection of fluorocarbons into the Martian atmosphere could do a lot to make it more Earth-like, melt the permafrost and so on. The other dome would be a social experiment which smacks of nineteenth century idealists creating utopias in the Amazon: people would live there as if on Mars (with as little communication with Earthlings) and try to set up social democracy or whatever to prove to the rest of us that everyone can live in peace.

Lord Young will get his money, it was confidently predicted. **Robert Walgate**

Do we need gene therapy?

SIR — A serious imbalance is creeping into discussions on human embryo research and the direction of clinical genetics.

The first paragraph of the Warnock report on human fertilization and embryology (para 1.1) says "It is now possible to observe the very earliest stages of human development, and with these discoveries came the hope of remedying defects at this very early stage"; a theme developed in paragraph 12.15. Edwards and Puxon (*Nature* **310**, 179; 1984) suggest that "such research could open undreamt-of-vistas of improvement and amelioration for mankind"; and Weatherall concludes his comment on gene transfection (*Nature* **310**, 451; 1984) with the statement "offers major encouragement to those who believe that the ultimate goal of clinical genetics is gene replacement therapy, rather than termination of pregnancy".

The belief that the ultimate goal of all clinical practice is to remedy the defect seems to be common among molecular geneticists as well as physicians involved in the treatment of genetic and partly genetic disorders. Patients and parents usually go along with this philosophy when the diagnosis is made after birth, or late in pregnancy, but it would be wrong to assume that this traditional goal of clinicians is necessarily appropriate for embryos with genetic defects.

Physicians and surgeons tend to forget that no matter how grateful patients or parents are for the effort and skill put into treatment, or how desperately they long for the research "breakthrough" that will allow improved treatment, they would much prefer to have no need of doctors at all. People do not want their babies to be medical successes, they want them to be normal. It will be argued that treatment will make them normal. But complete success can rarely be guaranteed in advance, and there is usually a considerable gap between what doctors and what patients regard as a success (although the latter may be too polite to say so).

The goal of correction of genetic defects rather than termination of pregnancy implies detection of the affected embryo in the first trimester of pregnancy even if therapy is carried out later. However, as someone who has close contact with couples making decisions about prenatal diagnosis and selective abortion, I believe that once the abnormality has been detected, most couples will opt for termination of pregnancy and "trying again", rather than chance treatment of the embryo or fetus. There is already widespread acceptance of selective abortion in early pregnancy, which can only be enhanced with the general realization that about 40 per cent of conceptions are lost as natural miscarriages (D.K. Edmunds *et al. Fertil. Steril.* **38**, 447; 1982), and close on half of early miscarriages are chromosomally abnormal (E.D. Alberman and M.R. Creasy *J. med. Genet.* **14**, 313; 1977). The advent of home pregnancy testing kits that confirm a pregnancy within two weeks of conception can only encourage the view that selective abortion is Nature's way.

It seems quite wrong for clinicians and scientists to assert that the goal for clinical genetics is gene replacement, when many, probably the majority of couples would not choose this option. It can only be one of several aims of clinical genetics. Certainly "the need to develop methods of gene replacement in embryos" cannot be regarded as a reason for allowing the creation of human embryos specifically for research purposes, until such a need has been demonstrated. It should also be remembered that 7 out of 16 members of the Warnock committee were against the creation of human embryos specifically for research purposes.

Science journalism

SIR — The editorial policy of *Nature* in declining for publication material that has already been communicated to lay or popular news media has provoked hostile reaction from those media, as exemplified by Mr Leif Robinson's letter (*Nature* 16 August, p. 536).

When I was first engaged in scientific research, it was accepted without question that one did nothing to invite publication of one's work outside the scientific literature-of-record, not only for fear of misrepresentation but also because it was regarded as unprofessional self-advertisement. Mr Robinson claims that by adhering to this ethic *Nature* is guilty of restricting the public's right to know the results of research.

He attempts to justify this assertion by arguing first that misrepresentation has become less of a danger with the recruitment of better qualified scientific journalists, and then that they can misrepresent research results just as easily after proper scientific publication as before. Clearly the two arguments largely nullify each other. The fact is that misrepresentation is less harmful if the true record has been published so that anyone who really cares about the truth can refer to it. As an aside, I do agree that there are now some excellent and professional scientific journalists, but the fact that coverage of science by the lay media in general still leaves much to be desired is illustrated by the example of the ludicrous reports of Soviet science which sometimes appear in otherwise respected newspapers "from our Moscow Correspondent".

Mr Robinson then destroys his own case by stating that science journalists will "ferret out stories", since to make a scientific result into a journalist's story is in itself distortion of a fundamental kind; there can of course be legitimate stories about science but that is different. Denial of the public right to information lies in giving the public a substitute account, not in insistence that what is published is a true professional and authentic record.

I conclude that *Nature*'s policy is correct even in relation to the considerations raised by Mr Robinson. In addition, and despite scientists who have attracted repeated press notice having behaved with integrity in not exploiting this attention unfairly, the climate for scientific research will remain healthier to the extent that young scientists are encouraged to publish for peer-judgement not public acclaim.

PETER FELLGETT

Department of Cybernetics,
University of Reading,
Reading RG6 2AL, UK

SIR — It ill becomes Leif Robinson (*Nature* 16 August, p.536) to upbraid John Maddox for reminding scientists and others of the fundamental importance of their voluntary code of practice regarding the announcement and publication of new results. It is natural of course that Robinson should do so, given that he evidently regards peer review as a potentially restrictive practice obstructing the free flow of information between scientists, the public and the press. The fact that scientific peers today often *do* look upon themselves as a kind of thought police, imperially appointed to defend some imagined consensus view rather than subjecting arguments to independent rational review, may partially condone the error. Nevertheless, it is sad that Leif Robinson, editor of a widely read popular journal of science, so fails to appreciate the true role of peer review in the scientific process that he appears to advocate its omission.

At the same time, another problem exists which Robinson's complaint does perhaps more directly address, namely the ethical dilemma that sometimes confronts scientists concerning publicity between the instant of acceptance and the instant of actual publication. In this age, there are scientists and institutions who no longer feel restrained by traditional practices and who seek increasingly to pre-empt such kudos as might otherwise accrue to the publishing journal by organizing their own publicity. If the editors of *Nature* wish to maintain their reputation as publishers of original new scientific results, it seems that they can succeed in this aim only by so marshalling modern technology as to reduce the interval between acceptance and publication to the absolute minimum.

Army pall over Argentine science

The destruction of science in Argentina will probably never be more than a footnote to the history of the recent military government, whose major accomplishment was the kidnapping, torture and murder of 30,000 of its citizens in the name of Christian and Western civilization. Official neglect of Argentina's dogged potential for scientific excellence is nothing new; inevitably, there is a tendency to see even the most deliberate and calculatingly destructive acts of the military as a mere extension of what passed before.

Buenos Aires, August

SCIENCE in Argentina has always mirrored the paradox of the country as a whole: a vast potential, occasional glimmers of greatness (which, in the case of science, include two Nobel prizes and an impressive home-grown expertise in nuclear engineering). But, overall, chaos. And scientists in Argentina have always sought out better opportunities in the United States and Western Europe.

However, it is the completeness of the military's crusade against the academic and intellectual life of the country that is so striking today when one visits Argentina's universities and research institutions. Research at the major universities is at a halt. Under the military regime, which seized power in 1976 during a rapidly deteriorating political situation that included frequent terrorist attacks, hundreds of academically unqualified — though politically acceptable — professors were appointed. More than 90 per cent of the faculty of natural and exact science at Buenos Aires University have been appointed since 1976; none can be fired. The selective persecution of individuals, but more importantly a general policy based on the premise that the universities were centres of subversion, accelerated the brain drain to the point where now almost an entire generation of Argentine scientists have been lost to the developed countries. The efforts of Argentina's new democratic government to reestablish contacts with its expatriate scientists has only now revealed the true extent of this loss: a list being compiled by the Argentine embassy in Washington of Argentine scientists who hold research positions in the United States now stands at 500. One is struck not only by the sheer size of the list, but by the quality of the positions as well. Massachusetts Institute of Technology, Princeton University, the University of Chicago and the University of California appear repeatedly.

Legacy

Although the election of Raul Alfonsin as president last December has brought about a remarkable and sweeping change in spirit within the academic world in Argentina, the legacies of seven years of military rule will be much harder if not impossible to eradicate. Bureaucrats left over from the military government remain within the agencies responsible for science; they cannot be fired and at least some are a continuing source of resistance to the reforms of the new government. A swollen organization of government-controlled research institutes is another onerous legacy. And then there is one inescapable reality that confronts every attempt at policy-making: Argentina's economy is a shambles. The external debt, to which the military government added more than its share, is $50,000 million. Inflation reached 22 per cent for the month of August alone, equivalent to an annual rate of almost 1,000 per cent. All business transactions are calculated in dollars; the recent revaluation in which four zeroes were dropped off the end of the currency has encouraged no one.

The Peronist legacy persists even in 1984.

Economics is the heart of the problem for the universities. The military's attempts to turn the universities into little more than secondary schools is readily apparent in its budget. The entire research budget for the faculty of exact and natural sciences at Buenos Aires is $200,000 a year, roughly one-fifth of its historical level. The budget for teaching expenses is $50,000. (These figures do not include salaries, nor research funds channelled through "institutes" that were set up at a frantic pace during the military government as a substitute channel for research.

Spending is being held at 1983 levels as the legislature has failed to act on the 1984 budget requests. The universities have been promised additional funding by the end of the year by President Alfonsin.

The other part of the universities' problem is personnel. According to Gregorio Klimovsky, dean of exact and natural sciences at Buenos Aires, one-third of his faculty simply would not have received their appointments during normal times. Klimovsky's effort to annul the appointments made during the military government has been blocked by the university's governing council. Klimovsky also complains that the university administration has taken no steps to rehire professors improperly dismissed, as provided for under a new law passed this year.

In the unlikely event that all of those dismissed do ask for their jobs back, there will not be much that the university could actually do. The problems go back a long way. In 1966, some 300 members of the science faculty resigned in the wake of a bloody seizure of the faculty by the military government (an earlier military government) that had come to power one month earlier.

In 1974, the unstable Peronist Government fired 400 faculty members and teaching assistants. And during the 1976 military government, all faculty and staff were required annually to fill out forms providing personal and background information to the various branches of the military and police in order to obtain clearance. In practice, the system lent itself not only to political persecution but to personal vendettas as well.

Klimovsky, who was one of the few who spoke out against the human-rights abuses of the military regime and who is now serving on the national commission investigating the "disappeared", says that approximately 60 scientists, mostly from the universities of Buenos Aires and La Plata, are believed to have been killed by the military regime. Some were politically active, others victims of denunciations. Klimovsky says that the commission believes that as many as half of the victims overall had been taken for questioning and either died under torture or were killed to conceal what was happening.

A huge banner hangs in the atrium of the faculty of sciences listing the names of the several dozen faculty members, students and graduates who disappeared, an overwhelming reminder of the brutality born of Argentina's political instability. That instability has not disappeared with the coming of the new government; and it is the major obstacle to Klimovsky's hope that many good scientists who left will return, eventually diluting the mediocrities who now flourish.

A certain amount of volunteerism has sprung up, to be sure. Many professors are working without pay while holding regular jobs elsewhere, often in industry. Some are paying for equipment and maintenance and subscriptions to foreign journals — two items especially squeezed by tight budgets — out of their own pockets.

But the prospects of attracting scientists who have settled in the United States or Europe to return seem slim even with the best will in the world. If nothing else, salaries are very low; a full professor earns about $700 per month; many senior researchers earn as little as $400 per month.

Some universities fared better than others under the military. At one extreme, Lujan University, which had been created only a decade earlier, was shut down completely in 1977. At the other extreme, Mar de la Plata University actually reaped the benefits of persecution elsewhere by hiring scientists fired from the University of Buenos Aires or other institutions. A major research group in biology was "rescued" in 1979 when Mar de la Plata hired four senior scientists, Horacio Pontis, Rafael Pont Lezice, Ruben Conde, and Gistavo Daleo, who had been dismissed three years earlier from the Bariloche Foundation.

How Argentina spends its research money

Atomic Energy Commission (CNEA)	22%
Ministry of Defence; Armed Forces	4%
National Institute of Industrial Technology (INTI)	10%
National Institute of Agricultural Technology (INTA)	22%
Universities	9%
National Research Council (CONICET)	32%
Total: $350 million	

Everywhere, however, certain disciplines suffered. Sociology and psychiatry departments were shut down across the board; they were, in the eyes of the military, lending "ideological support" to the leftist guerillas that the government was fighting. Psychiatry was suppressed, Freud being an "ideological criminal". In Cordoba, the military government's ideological enemies included the "new math", the teaching of which was banned by decree.

And even in those universities that were able to maintain research programmes, those programmes were circumscribed. At Mar de la Plata, materials research and agriculture continued; but a major fisheries research institute was taken over by the military under a new Secretary of Marine Interests. An agreement is now being worked out to allow Mar de la Plata to use the institute's three research vessels once again.

Some similar bits of reorganization are being attempted at Mar de la Plata and elsewhere to undo the damage done by the military, but without significant new funds they may accomplish little. Dr Enrique Schneck, secretary of science and technology at Mar de la Plata, has for example established a new programme of graduate fellowships — a signal of the intent to reestablish research at the university. But the funds for these fellowships have had to come out of undergraduate scholarships.

Universities

The efforts to return the universities to research is surely not going to be made any easier by the open admissions policies that the universities are adopting. Under the military government, applicants to the universities competed for a predetermined, limited number of places. This year, admission has been granted to any applicant who scores above a fixed qualifying level on entrance examinations. Next year, admission will be guaranteed to any student who has graduated from high school.

Perhaps the greatest obstacle to the restoration of research to the universities is, paradoxically, the generosity that the military regime showed for science elsewhere. The National Research Council (CONICET — Consejo Nacional de Investigaciones Cientifica y Technica) expanded rapidly during the seven years of military rule; from 1976 to 1983 the number of CONICET scholarships jumped from 233 to 2,222, the number of researchers (who are paid salaries, as in the French system) from 752 to 1,525 and the number of technicians from 569 to 2,185. During the 1970s, CONICET's budget increased sevenfold.

The military government's motive is not hard to find. CONICET, unlike the universities, is under direct government administration. An expansion of CONICET fitted in nicely with the military's objective of removing research from the universities. This is most evident in the proliferation of CONICET institutes that took place. In 1976, CONICET supported 48 institutes and centres; today, the number is 210.

The proliferation of institutes has balkanized the research effort. The individual institutes go their own ways, divorced from the universities and from each other. Many were clearly created to reward politically correct persons; many show a striking disparity between the elaborateness of their buildings and the meagreness of the research that goes on within. Several institutes are being examined by the federal prosecutor for misappropriation of funds, kickbacks and other questionable expenditures.

Because the universities have so few research funds of their own, CONICET is in the view of the new government the major tool for bringing research back to the universities. (CONICET has a budget of $120 million, or about one-third of the total government research and development budget. The universities altogether have a "research" budget of $30 million, or 9 per cent of the total, almost all of which goes for salaries.) Dismantling the institutes is harder than it might seem; as in the case of the universities, people cannot be fired. The Secretary of Science and Technology, Manuel Sadosky, has said that there will be no special investigation of individuals, but that over the next few years the institutes will be reviewed on the basis of their performance and that some may be shut down; Sadosky hopes, too, that new good scientists will dilute the mediocre.

Not surprisingly, CONICET is facing some stiff opposition from the many researchers who established comfortable fiefdoms in the existing system of institutes. Some discontents are circulating anonymous newsletters to hundreds of scientists, denouncing Dr Carlos Abeledo, the president of CONICET, Sadosky, and other officials as being part of the "antinational" Marxist left, which, in this version, apparently also includes imperialism and the international Jewish conspiracy. Several of these letters, signed by "Ameba Loca" (the crazy amoeba), make less veiled antisemitic references to Sadosky, who is Jewish. (The crazy amoeba calls himself director of the Organization of Information to the Scientific Community; another group calls itself the Committee for the Defence of CONICET. Several of the letters carry the message: "reproduction permitted only within the territory of Argentina".)

These groups, which apparently have no shortage of funds for printing and mailing these letters, have also recently taken to fabricating and distributing documents that seem quite damaging to CONICET officials. A recent one purported to be a blacklist of scientists who were not to be supported by CONICET in the future; most of the names are of scientists who were close to the military government.

Scepticism

These provocations are calculated to play upon the deep-seated scepticism that this government will be any different from its predecessors. CONICET officials say they are determined to avoid any favouritism in the award of research grants this autumn; the difference will be that all research groups will have to apply individually for grants — under the military, institute directors received grants in a lump sum, which they then distributed within their institutes as they saw fit. Proposals are due next month for 1985 grants.

Despite the military's support for CONICET, salaries slipped considerably. Earlier this month, President Alfonsin signed a decree bringing CONICET salaries up to par with those of comparable university positions; they had been about 30 per cent lower.

Amid all of the chaos of recent years, pockets of scientific research have enjoyed relative tranquillity. The most prominent of these is the laboratory of Dr Luis Leloir, Argentina's only living Nobel laureate. Leloir's institute, the Fundacion Campomar, has its own modern building, with an excellent research library and that most rare of Argentine scientific commodities, ample laboratory space. With an annual budget of $100,000 (not including salaries), the institute's 25 PhD researchers are considerably better off than most of their counterparts elsewhere in the country. A private endowment provides one-third of the funding; the remainder comes from about 100 private companies and foundations, CONICET, and the University of Buenos Aires, which pays most of the salaries.

Leloir's reputation, and the institute's private endowment, unquestionably helped to shield the institute from political turmoil. Leloir has directed the institute since its inception in 1947; he is a man who professes to have no opinions and indeed who has made a career of having no opinions; "Here we do not mix up in politics", he says.

Another organization that weathered the storm, though not so easily, is the National Institute for Research and Diagnosis of Chagas Disease. Chagas' disease, the South American equivalent of trypanosomiasis, affects more than 25 per cent of 18-year olds in Argentina. Although research came to a halt in 1981 when funds were shifted to a misguided effort by an army colonel in Cordoba to eradicate the disease, the institute has recovered well. A $90,000 capital grant from the World Health Organization has helped, and the government provides $400,000 per year, 25 per cent of which is used for salaries of the 70 staff members.

The mission-oriented research of the Chagas institute is an exception to the rule of Argentina's scientific expertise. Despite a considerable industrial potential (especially in food and petroleum), applied research is very weak; the best minds have consistently gone into very basic research. Industry in Argentina uses foreign technology almost exclusively; there is virtually no industry-supported research within the country. The scientists employed in industry perform routine quality control and engineering tasks.

Agriculture

Foreign technology has nevertheless proved remarkably successful in the agricultural sector, which remains the backbone of Argentina's export economy. The role of the National Institute of Agricultural Technology (INTA) has been to adapt foreign innovations to local conditions. Its 42 experiment stations and 240 extension agencies have few links with the universities or with basic research in general; arguably, there has been no need.

INTA's new president, Carlos Lopez Saubidet, is concerned, however, that this process of adaptation has reached its limit. Uniquely Argentine problems are emerging that will demand indigenous solutions; he points to the need for new methods of production in arid regions, for example, a necessity forced by the shift of cattle to these marginal regions as the productive lands of the pampas are increasingly put under continuous cropping of grains.

Lopez Saubidet is looking to the United States model of the land grant colleges, both to improve basic research and to institute training programmes. No universities offer PhDs in agricultural science; masters programmes have been in place only since the 1970s. Lopez Saubidet says that with the proper organization, existing expertise can be tapped to establish masters programmes at universities that do not now have them, in the areas of plant production, animal production, soil fertility and agricultural economics.

Biotechnology

Saubidet is also planning to tap the universities' expertise to start a new programme in biotechnology research. INTA has until now carried out all of its research in its own laboratories (which employ about 60 PhD scientists); this new scheme, Saubidet says, will probably involve outside researchers who will be supported by grants. The major goals of the biotechnology effort would be genetic improvement of plants, nitrogen fixation, drought resistance and vaccines.

INTA's budget has had ups and downs. In 1980, the military government eliminated a series of taxes and tariffs, including a 1.5 per cent levy on agricultural exports that had provided INTA's direct support. The tax has only now been restored, and should provide $90 million a year. In the meantime, the budget fell to half its historical level, with a staggering 80 per cent of the budget going to salaries. That proportion should fall to 60 per cent with the restoration of the tax base.

Saubidet has plans to free additional funds for research by phasing out activities that he believes can be assumed by private farmers. But one potential strain on the budget is the 150 or so employees who were dismissed for political reasons in 1976 and who now want their jobs back. (A total of 500 were dismissed in 1976.)

Efforts to bolster the ties between research and other industries face similar obstacles. The only PhD-level training programme is in chemical engineering; it began only in 1980. Most process plants are turnkey operations bought from abroad. The research departments that did exist in the chemical, food processing, and metal industries were the first things to go when economic problems intensified.

The National Institute for Industrial Technology (INTI) follows the familiar pattern of Argentine research organizations — fragmentation into small laboratories (about 40), a large proportion of the budget going for salaries (65 per cent), and isolation from basic science. INTI laboratories have drifted into the relatively easy business of providing technical services, such as chemical analyses, to industry; this now makes up 70 per cent of its activities.

Although INTI laboratories are well equipped by Argentine standards — they own $500 million worth of equipment and employ a staff of 1,500, including 500 scientists — operating funds have been tightly squeezed. The same 1980 tax reform that eliminated INTA's tax base wiped out INTI's — a 0.25 per cent levy on bank loans to industry. The budget fell from $40 million to half that: the tax base has not yet been restored. Nearly 300 of its staff were dismissed following this budget cut.

CONICET president Abeledo — under pressure.

INTI's current plan calls for concentrating on fewer areas, specifically food processing, electronics, fine chemicals, textiles, metrology and civil engineering.

The Research Committee of the Province of Buenos Aires (CIC) is shaping up to be another significant promoter of applied research. Under the new administration, CIC is, apparently for the first time, living up to its legal mandate of applying 60 per cent of its funds to mission-oriented research of local importance. The five areas chosen are natural resources, food technology, clinical research, non-conventional building technology and energy.

Angel Plastino, president of CIC, is also attempting to channel more of CIC's funds outside its six laboratories, to the universities. A major project under the natural resources programme is the first geological survey of the province's mineral resources. The project, which began in February in cooperation with the University of La Plata, is to cover the important mineral areas of the province in the first two years; the entire survey will take perhaps 10 years.

CIC's budget now stands at 0.5 per cent of the total provincial budget, twice its previous level; current plans call for a further doubling of the budget and of the number of scientists (now 250) supported by CIC. Plastino said that one key function of CIC in support of the universities will be the purchase of foreign books and journals for university libraries, which have deteriorated badly.

Several agencies of the federal government are trying to promote an initiative in biotechnology as a basis for future industrial growth. An acute shortage of microbiologists and fermentation scientists, and the pressure of economic realities have thrown cold water on some of the more optimistic plans (such as the proposal to build a $20 million biotechnology research centre). A more modest effort is now being planned by CONICET, in which investigator-initiated proposals will determine the scope and size of the programme.

The public health ministry is also interested in biotechnology, as a way for Argentina to get a foothold in the pharmaceutical industry. Although many international companies manufacture drugs in Argentina — 45 per cent of the market is locally produced — research activity is nil. Carlos Canitrot, the undersecretary for regulation (equivalent to the commissioner of the Food and Drug Administration in the United States), notes that to develop a new drug costs about $40 million; the largest pharmaceutical company in Argentina has sales of only $60 million a year. He sees biotechnology as a way of competing at lower costs, particularly in biologicals, vaccines and diagnostics.

Channelling local efforts into productive avenues is not going to be easy; much of the local "innovation" consists of formulating new combinations of drugs — some containing as many as five different active ingredients. And the drug regulation system suffered a near total breakdown under the military government.

Nuclear worries

The one area of applied science where Argentina is doing quite well is nuclear engineering. The concern in the rest of the world is that Argentina is doing a little too well. Last autumn, the outgoing director of the National Atomic Energy Commission (CNEA), Admiral Raul Castro Madero, revealed that Argentina had built its own uranium enrichment plant at the nuclear centre in Bariloche, in the south. Argentina has an abundant natural supply of uranium; it has long had its own fuel fabrication plant; it is in the process of building a plutonium reprocessing plant at the Ezeiza Atomic Centre near Buenos Aires, and, with Swiss help, a heavy-water plant with Arroyito.

Although the two power plants are under International Atomic Energy Agency safeguards, as are Argentina's research reactors (a necessity, since the enriched uranium fuel that powers the research reactors was provided by the United States), Argentina has consistently refused to sign the Nuclear Non-Proliferation Treaty (NPT). Mario Mariscotti, chief of research and development for CNEA, and widely considered to be the next in line as director of the agency, raises the familiar arguments that NPT discriminates against non-weapons states. He also complains of foot-dragging in technology transfer by the United States, particularly since India exploded its nuclear bomb. He argues that if Argentina can become independent in its fuel cycle, why should it give that up for the questionable and uncertain benefits of American aid? He tells of the United States backing out of an arrangement to supply enriched fuel for a plant that Argentina was building for Peru as an illustration.

Opinions differ about Argentina's technical capability to build a bomb. But there seems to be little doubt that it either has or could eventually produce the materials for one. The enrichment plant, which is not under safeguards — Mariscotti says that opening it to international inspection would itself constitute a proliferation risk — has a capacity of "less than a ton" of 8 per cent enriched uranium per year, according to Mariscotti. The maximum enrichment it can yield is 20 per cent. In principle, the unsafeguarded fuel from this plant could be burned in a research reactor to produce plutonium, which could then be reprocessed to yield bomb-grade material. Argentina is legally bound to accept safeguards only on the fuel (and the plutonium derived from it) that was originally supplied by the United States. Once the research reactors are being fuelled by its own uranium and heavy water — which is the offical plan — safeguards could legally be dropped.

Mariscotti asserts that Argentina currently has only "laboratory-scale" amounts of unsafeguarded uranium and plutonium. And he says that despite widespread speculation to the contrary, there never was a weapons programme under the military regime. He said he has not found it necessary to alter any research programmes out of concern that they were directed towards building a bomb.

But Argentina's fascination with nuclear research and development has always attracted suspicion. The programme was established in 1950 by President Juan Peron, and has enjoyed the special favour of every government since. Despite an erratic start under the direction of a German scientist, Ronald Richter, who at one point claimed to have developed a fusion reactor, the programme has produced results. Argentine physicists in the mid-1950s discovered several new radioisotopes using a state-of-the-art cyclosynchrotron; research programmes today show significant strengths in reactor chemistry, low-temperature physics, and radiobiology. A 20 MeV heavy-ion electrostatic accelerator (which cost $30 million) is nearing completion, and should permit state-of-the-art investigations. Yet it is frankly difficult to see how the benefits of CNEA's activities justify the costs. The two operating power plants (Atucha I near Buenos Aires, a 300 MW station and Embalse Nuclear Centre near Cordoba, 600 MW) supply about 10 per cent of the nation's electricity demand. A third plant now under construction (Atucha II) will supply an additional 700 MW. If three additional plants are built as planned, nuclear power will be supplying 15 per cent of the electricity by the year 2000.

All of the plants are of the heavy-water variety, which means they can use natural-enrichment uranium, although a better burn is achieved with 1 per cent-enriched fuel; the official plan is to use the enrichment plant to produce enough fuel to supply 1,000-MW-worth of power reactors, in addition to the 8 per cent enriched fuel needed for the research reactors.

CNEA's budget is $500 million per year, 10 per cent of which goes for research of which 10 per cent is basic research. National pride, the usual excuse given for this emphasis, is a less persuasive justification than it might be if the rest of Argentina's scientific and technical endeavours were in good shape.

The future

The difficulties that Argentina faces in rebuilding the scientific institutions it once had, in exploiting a potential that has never been significantly tapped, and in putting science to use for development are so enormous that they approach the absurd at moments. If it is no longer political persecution, it is low salaries; if the salaries are raised, there is still the shortage of equipment and foreign journals; if those problems should somehow be solved, there is still the mass of incompetents in high places; and the lack of the needed training programmes; and the brain drain; and, to top it off, the strike of clerical and janitorial help at the university that leaves the corridors ankle deep in trash and the phones unanswered.

That those now in charge of running Argentina's science have the best of intentions — and a sober vision of the problems — there can be no doubt. The emphasis on repairing the damage to the universities and on providing opportunities for the next generation of Argentine scientists is clearly the right one; there can be little hope that the many Argentines living in the United States and Europe will give up the security and prestige of their current positions in favour of the uncertainty in a country from which they not long ago fled.

If Argentina's leaders are a cause for optimism, though, its economy is surely a cause for pessimism. Sad to say that the future of Argentine science will probably have more to do with Argentina's woeful economy than with all of the careful planning and clear thinking of its new science administrators. ☐

Stephen Budiansky is Washington Editor of Nature.

Molecular biology of cancer

Last week's Nature *conference in Boston suggests that the study of oncogenes will provide a route to general understanding as well as a powerful insight into normal cell biology.*

THE molecular biology of cancer may almost be synonymous with the molecular biology of the cell. That is one of the impressions formed by last week's conference on the molecular biology of cancer. What seems to be happening is that the exceptional circumstances of malignancy (or of transformed cells in culture) is throwing a clear light on many aspects of the normal functioning of normal cells. Who would have guessed, even a few years ago, that so much would now be known about the biochemistry of the previously shadowy materials known as growth factors, for example?

So is the molecular biology of cancer merely another way of tackling longstanding problems of an academic character? That is the naturally impatient question asked by physicians, epidemiologists and the managers of public health. Patients also ask questions on the subject, and for good reason.

The answer, which is in the negative, is nevertheless a little roundabout. That the best cure for cancer is avoidance is undeniable. The worry, for now and for some time to come, is whether avoidance is feasible on the scale and at the speed to which agencies such as the US National Cancer Institute are committing themselves. Everybody will be delighted if the objective of reducing cancer mortality in the United States by half by the year 2000 can be attained. But even if the programme succeeds, there will still be more than 250,000 deaths a year from cancer in the United States. So the need for better treatment will still be as clamant, for which purpose only a better understanding of the manifestations of forms of the disease can provide.

In this sense, the two approaches to the problem of cancer—avoidance and understanding—are complementary. But they are more closely linked even than that. The strategy that emphasizes avoidance (the best course) requires that people should change their ways, sometimes radically. Public authorities, which have a constitutional licence to fix tax rates and speed limits, are conspicuously successful at changing their electors' habits. Understanding, however, may in the long run accomplish what exhortation cannot. And the molecular biology of cancer is more likely to provide persuasive general understanding than some of the advertising campaigns manned for the years ahead.

Synthetic genes

Transgenic mice inherit cancer

MAKE your own oncogene, Dr Philip Leder's recipe for grafting the regulatory sequences of the mouse mammary tumour virus (MMTV) onto the coding sequences of the c-*myc* gene, was the biggest sensation last week.

The circumstances are clearer than the full significance. The c-*myc* gene appears to be responsible for human lymphomas when translocated from its normal position on chromosome 8 to somewhere among the immunoglobin genes on chromosomes 2, 14 and 22, presumably because the regulatory environment then allows it to be activated. But the *myc* gene is a curious structure, with a long (more than 100 base-pair) sequence upstream of the first of three exons, which is duly transcribed into RNA but which (together with a short stretch at the beginning of the second exon) plays no part in coding for the gene product. So why not equip the gene with indigenous control elements by replacing the upstream end by a known regulatory element?

Fusion genes on this pattern are made from the regulatory elements of MMTV and the *myc* gene from which various upstream regions have been removed. In fertilized mouse oocytes, the synthetic genes become part of the genetic constitution of transgenic mice. In adult females, the gene should be turned on during pregnancy, as MMTV is activated by hormonal influences.

The offspring of two of the transgenic mice produced in this series of experiments turn out to have inherited MMTV-*myc* fusion genes, most remarkably in the case of four daughters of a transgenic mouse provided with the bare minimum of c-*myc*—the coding parts of the second and third exons, the intervening sequence and the downstream tail of the gene.

The pathological effects of the synthetic oncogene are distinct from those of MMTV and of c-*myc* but result, rather, in a distinctive adenocarcinoma of the breast tissue appearing only after pregnancy (confirming the influence of the lactational hormones). Offspring have been salvaged from these pregnancies (transgenic females are bad mothers, perhaps not coincidentally) by fostering, and the females turn out to have inherited both the fusion genes and the characteristic pathology of their mothers.

The mere development of this mouse strain confirms current notions that c-*myc* gene in the human genome is, in its normal position on chromosome 8, repressed (by some unknown mechanism), but that translocation to some other site allows it to be expressed. In this respect, c-*myc* differs from the *ras* oncogene, the activated form of which is now known to produce a protein distinct from the normal variety.

Potentially, the new strain of transgenic mice is a valuable model for the study of gene regulation and of oncogenesis, or at least of that for which *myc* is responsible.

The view that *myc* is normally suppressed, which Leder describes as a speculation, is consistent with the association of human lymphoma (and its mouse equivalent) with translocation but also with comparisons of the structure of the long leader sequence ahead of the three *myc* exons in the genes from mouse and human beings. These have substantially diverged from each other in the course of evolution except for a short region of some 200 base-pairs, most graphically seen in heteroduplex structures made from a DNA strand from each species, which may be the site of repression.

Functionally, c-*myc* normally appears to be active only in the cell cycling of precursor white blood cells. In culture, the cell products appear 3–6 hours after the treatment of resting cells with platelet-derived growth factor (PGDF). Of the importance of its abnormal functions in differentiated lymphocytes, there is however no question. Leder was one of several speakers who last week drew attention to the demographic importance of Burkitt's lymphoma in, for example, West Africa. □

Longer list

ROBERT WEINBERG, much involved with the characterization of the activated form of the H-ras oncogene, now has another. Last week, Weinberg described the isolation from a chemically initiated neuroblastoma in rats of an oncogene different from those already known.

Neither the sequence of the new gene nor the function of its product is known as yet. Indeed, the 85,000 molecular weight protein identified on the neuroblastoma cell surfaces may not be coded for directly by the oncogene, but could in principle be a secondary product thereof.

But the protein and the epidermal growth factor receptor are cross reactive, suggesting similarity falling short of identity.

So how many more oncogenes will be found? Weinberg reckons that the next three or four years will bring a further dozen. Obviously the effort will yield diminishing returns, but nobody can know how long the list will be.

Already the list is long enough for classification to be meaningful. Weinberg would divide them into transforming oncogenes (such as the ras genes) and the immortalizing genes (such as myc). And the effects on cells are similarly categorized—some (e.g. sis) allow cells to make their own growth factors, some (erb-B) alter growth factor receptors and other (H-ras) may change the regulation of cell biochemistry. □

Binary toxin

COUPLING cytotoxic drugs to antibodies has during the past few years been a commonly favoured strategy for killing specific cells. Dr J. Uhr explained last week his strategy for the development of immunotoxins from the natural product ricin—a constituent of the castor bean. The protein molecule consists of two chains (A and B) which are separated within cells, whereupon A becomes lethal (one molecule, one cell).

Uhr's objective is to couple ricin, and ricin A chains, separately to immunoglobin molecules raised against specific antibodies on circulating B-cells. The objective is the high cell specificity that would promise the avoidance of side-effects in therapy. A spontaneously arising B-cell clone is being used as a test system for telling whether the effects of A-chains might be potentiated by the manipulation of intracellular conditions or even the use of ricin B-chains also tagged to immunoglobin molecules. □

AIDS

Bad news, good news

ROBERT Gallo spread a sense of urgency last week about the HTLV group of retroviruses, and especially about HTLV–III, which he and his associates have done most to establish as the agent of AIDS (autoimmune deficiency syndrome). Since the publication of the evidence for the identification of the virus earlier in the summer, complications have arisen.

Gallo's bad news, derived from nucleotide mapping and sequencing, is that HTLV–III may vary considerably in its nucleotide sequence from one patient to another; whether this will affect the outlook for the preparation of vaccines will depend on whether the antigenic sites are affected. The news that AIDS has been recognized among adults with only heterosexual partners, and that (according to some reports) up to 5 per cent of blood offered for transfusion in the United States may be contaminated, suggests that the virus may already be more widespread among the human population than its overt manifestation implies.

The good news is that Gallo and others have cloned the gene, and that its nucleotide sequence is nearly complete. The development of diagnostic tests for AIDS is also well advanced—so much so that physicians are already worrying what they will tell their patients when they have concrete information to give them. And, small comfort though it is, the association of HTLV–III with AIDS, and the prevalence of the disease, is such that Gallo was able to say last week that "we no longer need an animal model for AIDS".

Why should a virus whose effect on the T cells it infects is to kill them feature among oncogenes? Gallo's sober answer is that HTLV–III, like the two other human T-cell viruses now known, is a retrovirus with similar specificity, with HTLV–I now emerging as the agent of the adult T-cell leukaemias (ATL). The more memorable way of putting it is the rhetorical question "Why not use HTLV–III to treat the leukaemias and HTLV–I to cure AIDS?" (The suggestion will not work because different "subsets of subsets of T cells" are responsible for the deficiencies of the immune system that characterize the two groups of diseases.)

Gallo's obsession is to see a vaccine in trials and eventually in general use. Like everybody else, he is infuriated by the knowledge that as things are, it is possible only to treat the adventitious aspects of the syndrome, Kaposi's sarcoma or whatever. The evidence, as he sees it, that the disease is spreading beyond the groups of male homosexuals and haemophiliacs dependent on injected Factor VIII makes the search more urgent. □

Some success with interferon

SUCCESS in the use of interferon in the treatment of serious cancers is beginning to trickle in. That was the burden of the report by Dr J. Gutterman of his own group's use of interferon, both alpha and gamma interferon and naturally occurring (and thus heterogeneous) and genetically-engineered material. But the development of therapeutic regimes is painfully slow.

Gutterman described the use of alpha interferon in a group of 27 patients with chronic myeloid leukaemia (CML) in which the underlying defect is a translocation from chromosomes 9 to 22. Only 3 of the 27 patients had failed to go into remission after the administration of interferon, although the question cannot yet be regarded as resolved, given the long duration (3.2 years average) of the chronic phase. But Gutterman says it is encouraging that in many of the patients treated, the proportion of cells with abnormal chromosomes in bone marrow had been markedly reduced, in some cases apparently to zero.

Gutterman also described the successful treatment with gamma interferon of 10 (out of 11) patients suffering from hairy cell leukaemia, and the generally successful amelioration of Kaposi's sarcoma (an accompaniment of AIDS) with alpha interferon.

Even so, the development of effective means of using genetically-engineered and naturally occurring interferon will be an enormous task. Alpha and beta interferon (which share the same cell receptors) do not potentiate each other, but alpha and gamma interferon are mutually synergistic, which argues for appropriate mixtures, not yet defined.

Even more daunting is the need somehow to distinguish between the constitutional genetic variants of three types of interferon specified by the human genes. Clinically, for the time being, this problem has been left on one side.

On the side-effects of interferon therapy, Gutterman says that the chief effect seems to be a loss of "executive function", a lassitude, which psychologists describe as a reversible biochemical lobotomy.

With the need to distinguish between all the possible variants of interferon, Gutterman considers there is an urgent need to define various types of cancer in terms of "early molecular events" so as to be able to make use of accumulating knowledge of the role of interferon and of other lymphokines in the physiology of body cells. □

Growth factors

Ambivalence in plenty

GROWTH factors may inhibit growth, and inhibitors may sometimes have the opposite effect. This ambivalence of the compounds on the steadily lengthening list of the gene products of the known oncogenes emerged most clearly from Dr Michael Sporn's survey of the field last week.

Much of the interest at last week's conference has been stimulated by the recognition that the interaction between growth factors and oncogenes may be crucial to the development of malignancy. Notable among these are the links between the *sis* oncogene and platelet-derived growth factor (PDGF) and between the *erb*-B and the receptor for epidermal growth factor.

Dr P. Newmark (Deputy Editor of Nature*), Dr P. Leder and Dr R. White.*

Sporn emphasized last week the common features of the architecture of many of the growth factors whose role in carcinogenesis is coming to light. Although similarities of amino-acid sequences ("homologies" in slang) are many fewer than might have been expected, Sporn and Dr George Todaro agreed that the character of the molecules is determined by three disulphide bonds between as many pairs of cysteine molecules. (Insulin, two peptides held together by two disulphide bonds, is—significantly—not very different.)

So the hunt for growth factors which are somehow linked with oncogenes is now fast and furious. Sporn reported last week a significant difference between the two versions of the growth factor TGF (for tumour growth factor) called alpha and beta, which have been isolated from rat tissues (among others). Heroically, Sporn and his colleagues have been able to determine the sequence of beta-TGF by wringing 40 micrograms of pure substance from 14 kg of bovine kidney.

Although similar in their architecture, the two molecules differ profoundly in their effects on cells: alpha-TGF is always stimulatory of cell metabolism, beta-TGF may be inhibitory. This argues for distinct receptors but also for the more philosophical view that growth factors are regulatory elements in the same category as some hormones (insulin), the lymphokines (interleukin I and II for example) and the interferons which are recognized as "growth factors" only in relation to malignant cells.

Sporn and Todaro agree on the importance of deciding how the growth factors produced by transformed cells play a part in malignancy as such. On the autocrine model, cells produce growth factors which stimulate themselves. Todaro thinks the circumstances may be rare, perhaps occurring in Weinberg's transformed neuroblastoma cell-line. Whatever the detailed mechanism, Todaro thinks it likely that the effects of the secreted products of oncogenes on cells (including themselves) may be to activate proteases (perhaps by phosphorylating tyrosine residues) which then cleave precursor molecules to yield activated growth factors, much as proinsulin is converted into insulin.

The interest of Todaro, now more than a year with the company Oncogen, is guided by the suspicion that the common recognition of growth factors produced by transformed cells may conceal the way in which, in normal tissues, their stimulatory effects are balanced by those of inhibitory factors. Against some of the odds called in recent years, shadowy materials such as tumour necrosis factor (TNF) are now well on the way to being characterized. Todaro's people are embarking on assays of these and other materials in the urine of cancer patients, processing up to a litre of urine at a time in what seems to have been a successful if preliminary demonstration that TGF is secreted in cancers of the lung, breast and colon, and in melanoma, but not by leukaemic patients or normal controls. Who said that molecular biology is picobiochemistry? □

Front end virus

CLINICIANS, these days, are as often as not closet molecular biologists. Dr Samuel Broder said last week that working with T-cell leukaemia virus is the "front end of cancer". There is, he said, a "basic duality" in knowing whether the conditions that arise are direct consequences of the neoplasm or secondary consequences of the immune suppression accompanying T-cell leukaemia. □

Biology

No genuflection

CANCER may not be what it seems even now, oncogenes notwithstanding. That was the theme of the iconoclastic message delivered by Dr John Cairns (now at the Harvard School of Public Health) in a clear English accent.

After "genuflecting" towards the oncogene, Cairns faced the conference with interlocking pieces of evidence that the development of malignancy in a cell is a long-term process, as follows.

- Irradiate cells in culture, allow them to grow to fill up the culture dish and, after 10–12 generations, the number of malignant foci will be that determined by the Poisson statistics describing the distribution of rare events. In a parallel experiment, remove part of the cell mass; the average number of malignant foci will be the same. But trypsinize the cells to break up the cell mass at an intermediate stage, and the number of foci will increase, suggesting that the progeny of a large proportion of the original cells have inherited the propensity to malignancy.
- Paint rabbits' ears with coal-tar (following 1920s' experiments by Peyton Rous), sampling tissue by some traumatic procedure (such as using a punch); the outcome suggests that many more cells are rendered by the trauma susceptible to transformation than become malignant under the influence of the promoter.
- The incidence of lung cancer and smoking in human beings argues that the development of malignancy must require both early events (because lung cancer develops only after long exposure) and late events (because giving up the practice sharply reduces the relative risk within two or three years).

In the interpretation of these and other data, Cairns said that "we have been brainwashed by current ideas of evolution and mutagenesis". In his view, both the arguments of Gould and others in favour of "punctuated equilibrium" in evolution and Barbara McClintock's work on the occurrence of mobile genetic elements in maize suggest that "mutation rates are not constant" but are, instead, increased by "genomic stress".

To molecular biologists, Cairns commended the study of long terminal repeats and of parvoviruses. In his opinion, the study of the role of hepatitis-B virus infection as the stimulant of liver cancer is, numerically, the most valuable contribution that could be made. But for those who would reduce the mortality from cancer, the objective should be prevention of cancers with known causes. The role of diet is obscure and needs urgent investigation.

Oncogenes, Cairns says, will "give us a fascinating insight into how cells manage their affairs" but will not contribute to public health in the near future. □

Somatic genes

Ways with drug resistance

ONCOGENES are merely the frosting on the cake of the application of molecular biology to the problem of cancer. By common consent, last week, the need to trace the effects of the gene products through the biochemical apparatus of the cell is plainly urgent. Why does the activated (mutated) *ras* gene have such profound effects? The first steps in what may be a long cascade have been described (see *Nature passim*). Other areas cry out for attention.

Alexander Varshavsky's account of the phenomenon of the acquired resistance of cancer cells to not just one but several cytotoxic drugs suggested a fruitful field for investigation. The problem all too often presents itself in the chemotherapy of cancer patients. Although Varshavsky was at pains last week to emphasize that multi-drug resistance can be acquired in several different ways (mutation of the target gene which may make its product less susceptible to attack by cytotoxic drugs, other mutations which may affect the regulation of the gene or the import and export of the cytotoxic drug through the cell membrane), the mechanism of gene amplification is the most commonly discussed.

Whatever genes are amplified may be up to 600 times more common in drug-resistant cells, for which reason Varshavsky argued strongly for direct interaction between drug and DNA rather than for the evolution of a labile genome under selective pressure. Many of his audience were eager to know why hydroxyurea should apparently be a powerful stimulus to resistant cells (in culture) to shed copies of the resistant genes (but could not be satisfied). The practitioners' concern is to characterize those genes which are amplified in resistant cells and whose functions are not already known. (Resistance to methotrexate usually entails the amplification of the gene for dehydrofolate reductase, but multi-drug resistance seems often to involve a decrease of membrane permeability to the drug associated with amplification.) Varshavsky and his associates are struggling with genetic fragments more than 1,000 base-pairs in length, but Dr John R. Riordan (Hospital for Sick Children, Toronto) offered the information that a relatively small glycoprotein (molecular weight about 20,000) has been consistently isolated from multi-resistant cells.

Genetic amplification causing drug resistance is one thing—genetic changes in somatic cells associated with cancer, or in germ cells which carry a predisposition to certain forms of cancer, are another. R. White left his audience last week with two clear impressions. First, the map of the human genome is now reasonably well sprinkled with potential genetic markers so that the identification of the usually rare genes carrying a predisposition to hereditary cancers may often be successful. Second, the interlocking familial studies of cancer incidence and genetic constitution based in Utah (whose large Mormon population makes the construction of kindred trees more feasible) has already provided an invaluable resource for the investigation of the genetics of cancer incidence. Dr F. Gilbert confirmed the practical potential of such developments.

The genetics of carcinogenesis, and of tumour promoters, is in a different ballpark. I. B. Weinstein was anxious that people should understand that the effects of tumour promoters on the cells in which they engender malignancy are usually direct, not via the genome. So much is clear from studies with protein kinase C (PKC), whose targets include a growing list of the molecular components of cells such as growth factor and insulin receptors and even myelin basic protein.

These lines of development are quite distinct from the pursuit of oncogenes. They offer the prospect that even when the list of oncogenes is complete, there will remain as vast a canvas as that which now appears to stretch ahead for the exploration of how malignant cells are the products of their genes. □

Avoidance is the best cure

CANCER as a preventable disease, the ideological basis of the National Cancer Institute's National Cancer Control Program, was urged on the conference last week by Dr Richard Peto. He urged a clear distinction between the identification of causes and of mechanisms, and that "it is possible to show that the disease is avoidable without knowing how to avoid it".

The argument is epidemiological: if cancer rates vary over a wide range from one part of the world to another, and if people migrating to new dwelling places acquire the cancer rates of their new surroundings, it follows that cancer is not an externally determined fate.

Within developed countries, Peto says, tobacco consumption is responsible for 35 per cent of cancer mortality, and for one million deaths a year worldwide. Peto's rearrangement of priorities on the international demographic canvas puts liver cancer following hepatitis-B infection high on the list—100,000 liver cancer deaths a year in China alone. □

Strategy

How to reduce mortality?

REDUCING the rate of cancer mortality in the United States by half by the end of the century, the National Cancer Institute (NCI)'s promise to the US Congress last November, requires only the application of knowledge now available according to Dr Peter Greenwald of NCI. With present cancer rates, and allowing for the age-structure of the increased population of the United States by the year 2000, annual cancer deaths would increase from 414,000 to 575,000. So NCI's goal is to reduce the annual mortality to 288,000.

Reduction of cigarette smoking should yield a 15 per cent reduction in mortality, as should the extension of improved methods of treatment to the whole country and the use of techniques (such as body scanning) for the detection of micrometastases. Perhaps the most controversial element of NCI's prospectus is the calculation that cancer mortality will be reduced by 5 per cent by changes in US diet (more fibre, less fat), chiefly by effecting a reduction of mortality from colon cancer. Persuading people to change their diet is uncharted territory. Continuing professional disputes about the efficacy of fibre in reducing colon cancer should, however, in Greenwald's opinion, be outweighed by the number of reports tending in this direction.

Greenwald says that NCI's new objective is deliberately to apply present knowledge in the avoidance and treatment of cancer. Hitherto, he says, reports identifying the causes of cancer have been published, but little has been done to show that agencies such as NCI can successfully intervene. The objective for the coming decades will be to mount demonstration projects which can thereafter be applied elsewhere in the United States. In this programme, Greenwald says, molecular biology may have important functions to perform as, for example, in the identification of the mutagens presumed responsible for cancer of the colon, now the second cause of cancer mortality in the United States.

The cost of the Cancer Control Program is necessarily speculative at this stage. Greenwald hopes that funds will begin to appear in NCI's budget with the beginning of the next administration next January. By the end of the century, the cost will be $10,000 million. The spur is that for each of the known causes of cancer in the United States, there is some society elsewhere which seems successfully to have avoided it. And even within the United States, the mortality from cancer among Seventh Day Adventists in the western states is only two-thirds of the national average. □

Cometary exploration

Plans for future space missions

from Alan Johnstone

IT may seem premature to plan more space missions to comets before any of the group of five now scheduled to meet Halley's comet in 1986 have even left the ground, but such is the interest in this comet and so long is the time required to prepare a new space probe, that planning for the next generation of spacecraft is already underway.

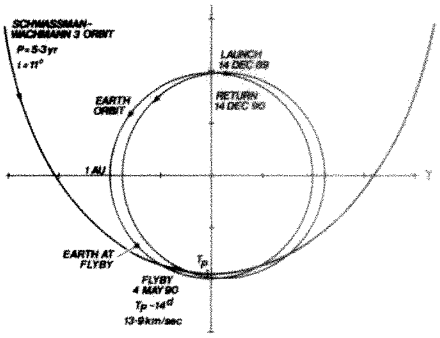
All the missions planned so far are flyby ones, that is, they will make one pass through the coma at the high velocity of 67 km s^{-1}. Giotto, the European Space Agency's (ESA) mission, which will be aimed closer to the nucleus than any of the two Russian and two Japanese spacecraft, will collect data on the composition of the comet over only four hours. These data will be collected by automatic instruments, set up beforehand to operate in the conditions believed to exist near the nucleus. There will be no opportunity to make adjustments during the flight. Despite the difficulties, a flyby mission is the proper first step in cometary exploration and the first measurements actually made within the coma of a comet, rather than on the radiation coming from it, will revolutionize cometary science.

A consensus now exists among cometary physicists about the form that the next steps in cometary exploration should take. First priority is a rendezvous mission in which the spacecraft is manoeuvered to be in the same orbit around the Sun as the comet. This will enable the comet to be studied as it passes from several astronomical units into perihelion and out again. Furthermore, as the spacecraft observes the development of the coma, it will be able to move at leisure through all the important regions. The difficulties are that such a programme requires advanced propulsion systems and is limited to the study of an unimpressive group of comets — those deflected by the gravitational effect of Jupiter into orbits which keep them in the inner Solar System. Nonetheless, one is being planned for the mid 1990s as a joint US-FRG venture.

For those interested in the composition of the comet and the origin of comets and the Solar System, the ultimate aim is to bring back to Earth a sample of cometary material — ideally, a piece of the nucleus — to be analysed in the laboratory using a formidable array of sophisticated techniques (Niehoff, J. *Comet Sample Return Mission Techniques*, Eur. planet. Sci. Symp., Heidelberg, April 1984). This kind of mission involves all the difficulties of a rendezvous mission, with the additional problems of acquiring and returning a solid sample. It will not be undertaken this century.

A much less difficult mission is to collect coma dust and a gas sample. The samples are collected on special plates carried on a simple flyby spacecraft which then returns to the Earth in its natural orbit and ejects the samples in a re-entry probe to be recovered as it descends through the atmosphere on a parachute. Engineers and scientists from NASA and ESA are currently studying the feasibility of a mission using a second model of the Giotto spacecraft. Its dust shield would be modified to carry the collectors, consisting of a number of cells or compartments covered by a thin diaphragm. Dust grains vaporize when they strike the diaphragm and the resulting gas condenses on the specially coated walls of the cell from where it can be recovered and studied in laboratories on the ground. Plane coated surfaces would be used to collect coma gas molecules. It is even possible to collect dust particles nearly intact by decelerating them slowly in a foam material that does not overheat the particle. Although some of the outer layers are removed in the process, 80 per cent of the particle can be recovered and its mineralogy studied. After encounter, the collectors would be retracted and stowed within a re-entry capsule mounted within the space now occupied by the rocket motor. This rocket injects the spacecraft into an orbit around the Sun; the need for it in Giotta 2 could be removed by using an appropriate launch vehicle. The rest of the instrumentation on Giotto would remain the same and would be used to study a second comet.

Several targets have been identified in the years 1989–1994. For example, a probe launched on 14 December 1989 would encounter Comet Schwassmann — Wachmann 3 on 4 May 1990 and return to the Earth on 14 December 1990 (see the figure).



The trajectory profile for Schwassman-Wachmann 3 coma sample return. *P*, period; *i*, inclination; T_p, time of perihelion.

The provision of the spacecraft by ESA would be much less expensive than usual since the spacecraft would be made to an existing proven design as a continuation of the present project. NASA would provide the re-entry probe and the launcher. Thus an exciting new mission could be achieved quickly, at a fraction of the cost of developing a planetary mission from scratch. ☐

Diabetes

On the track of viruses

from Abner Louis Notkins

THERE are two major forms of diabetes mellitus: the insulin-dependent (IDDM) type, often referred to as juvenile diabetes, and the noninsulin-dependent (NIDDM) type, also known as maturity-onset diabetes[1]. IDDM is caused by destruction of the insulin-producing β cells in the pancreas which results in hypoinsulinaemia and hyperglycaemia. The pathogenesis of NIDDM is less well understood. In this form of diabetes, there is little evidence of β-cell destruction and insulin levels in the blood are generally within the normal range. There is evidence, however, that in some cases the functional capacity of β cells, as measured by glucose-stimulated insulin release and/or the capacity of peripheral tissues to metabolize glucose, is impaired. It has been known for several years that in experimental animals, the destruction of β cells by acute viral infections can cause IDDM[1,2]. Now, in a recent issue of *Science*, Michael Oldstone and his colleagues show that in mice, a nondestructive but persistent viral infection of β cells can result in a condition resembling NIDDM[3].

Extensive studies over the last decade, especially with encephalomyocarditis (EMC) virus, have shown that the development of virus-induced IDDM in mice depends on the genetic background of the host (only certain inbred strains of mice develop virus-induced diabetes) and the genetic make-up of the virus[1,2]. The severity of the disease is directly related to the number of β cells destroyed by the infection and, in some cases, several insults are required to produce sufficient β-cell damage to result in clinically apparent diabetes. Variants of Coxsackie B viruses, Mengo virus and reoviruses also have been shown to damage β cells and produce diabetes. In humans, several lines of evidence including sero-epidemiological data, histological surveys of human pancreas, virus isolation and animal inoculation studies suggest that viruses, especially members of the Coxsackie B group, can actually cause or at least serve as the final insult in causing some cases of IDDM[1,2]. The number of well documented cases is small, however, and if an acute destructive viral infection is a major cause of IDDM, then that virus has not yet been isolated.

Recently, it has been observed that many patients with newly diagnosed IDDM, but not NIDDM, have autoantibodies in their sera that react with cells in the pancreatic islets of Langerhans. In fact, in some patients, these islet cell autoantibodies appear many months and even years before the development of clinically apparent IDDM[4], suggesting that this disease may have a slower or more chronic course than previously suspected. Whether these autoantibodies cause the disease or are the result of it and whether their appearance is genetically programmed and/or triggered by environmental agents, such as viruses, is not known. The possibility that viruses might sometimes trigger the production of autoantibodies is receiving considerable attention and several models exist[5]. For example, reovirus causes an autoimmune polyendocrine disease in mice; human B lymphocytes immortalized by Epstein–Barr virus make autoantibodies that react with a variety of human cells, including β cells; and some monoclonal antiviral antibodies cross-react with normal tissues (that is, molecular mimicry), including β cells.

The experiments of Oldstone and co-workers provide still another mechanism by which viruses might cause diabetes, particularly NIDDM. In earlier work, they showed that lymphocytic choriomeningitis (LCM) virus, which produces a persistent infection in mice, could shut off the luxury functions of differentiated cells (for example, the capacity of pituitary cells to make growth hormone), while leaving their vital function intact[6]. In the present work, by hybridization *in situ*, immunofluorescence and electron microscopy, they show that LCM virus produces a persistent infection in β cells. The infected cells appear to have normal morphology, their insulin content remains within the normal range and there is no inflammation. Nonetheless, glucose levels are elevated and glucose tolerance tests are markedly impaired. Precisely how LCM virus alters glucose tolerance tests has not yet been determined, but based on Oldstone's earlier work, impairment of the luxury function of β cells would seem a likely possibility. Careful studies *in vivo* of the function of hormone-secreting cells, especially glucose-stimulated insulin release, should be revealing.

The idea that viruses, and, more particularly, persistent viral infections, might sometimes be involved in NIDDM is supported by other lines of evidence[2,7]. In mice, retroviruses have been observed in β cells and herpesviruses have been found in the islets of several species. In hamsters, infection with Venezuelan encephalitis virus causes impairment of glucose-stimulated insulin release for several months in the absence of permanent morphological changes in the islets. *In vitro*, this virus-induced β-cell defect can be corrected by analogues of cyclic AMP or by inhibitors of phosphodiesterase[7], but whether the virus actually persists in β cells has not been determined. At the human level, some of the most convincing evidence for a viral involvement in diabetes comes from studies with rubella, a virus that sometimes produces a persistent infection. In patients born with congenital rubella the likelihood of developing diabetes in the first several decades of life (predominantly IDDM, but also NIDDM) is 10–20 per cent, compared to 0.1–0.2 per cent in the control population[8,9]. How the infection actually causes diabetes is not known.

Clearly, much remains to be learned. Nonetheless the concept of virus-induced alterations in luxury function and the demonstration that viruses can establish a persistent infection in β cells opens up a whole new area of exploration concerning the possible aetiology of both IDDM and NIDDM.

Particle physics

Nearly the 'top' conference

from David J. Miller

DISCUSSION at the 22nd International Conference on High-Energy Physics held in Leipzig, GDR, on 19–25 July, centred round the possible detection of two so far unobserved components of elementary particle theory. Very recent experiments at CERN, Geneva, and at the Deutsches Elektronen Synchrotron, Hamburg, have discovered what may be the heavy 'top' quark and Higgs particle respectively, and the conference was the first opportunity for many in the high-energy physics community to form their own opinions as to the strength of the evidence.

The top quark was predicted to exist. Physicists do not yet know why the fundamental spin-1/2 particles are arranged in three 'generations', each with a larger mass, but the pattern is clear. Normal matter contains only the first generation: two light quarks, 'up' and 'down', along with a lepton, the electron. In nuclear β-decay, up and down quarks can transform into one another, producing a positive or negative electron which forms the β-radiation and the electron's neutral partner, the neutrino. The 'strange' quark, the 'charmed' quark, the muon and its neutrino form the second generation. Particles carrying strangeness or charm eventually decay to normal matter and muons decay to electrons. The third generation is so far incomplete. The 'bottom' (or 'beauty') quark is securely established as a heavy equivalent of the down and strange quarks. The tau lepton is just like a heavy electron or muon, and in its decays it behaves as if it had its own kind of neutrino, though the tau-neutrino has not yet been directly observed. To complete the conventional picture of the quarks we need the top (or 'truth') quark, which should be like a very heavy equivalent of the up and charm quarks.

R. Bock (CERN) presented the UA1 collaboration's result. In proton–antiproton collisions at the CERN collider, the group has seen several events that contain a high-energy lepton (an electron or a muon) and two narrow 'jets' of high-energy particles, together with an apparent 'missing energy'. The group claims these events could be a result of the production of the W^+ boson (discovered last year at the same machine by the UA1 and UA2 experiments) which is predicted sometimes to decay to a top quark and a bottom antiquark. The energy of the lepton, and its angle to the jets, requires that it be produced by the decay of a very heavy particle, consistent with the top quark. The evidence is only circumstantial and there is room for other explanations. The number of events observed (three with muons and three with electrons) is a little larger than predicted and UA2 has not yet reported a clear signal for the process. If the top mass is eventually established to be between 30 and 50 GeV, then UA1 may well be credited with the discovery, but many would say "not yet".

The Higgs particle is another unobserved component of the conventional picture of elementary particles. It is a spin-zero object, postulated to provide a basis for the properties of the other integer-spin particles which generate the electroweak forces, the photon, the W^+, W^- and the Z. Perhaps the best candidate for the Higgs particle so far was reported at Leipzig by those involved in the crystal ball collaboration, working on the DORIS II machine in

Hamburg (see Walgate, R. *Nature, News & Views* **310**, 546; 1984).

They use a hollow sphere of sodium-iodide detectors, which gives unequalled acceptance and energy resolution for γ-rays, to look for line spectra in the decay of the 'upsilon' states, the 'bottom–antibottom' analogues of the J/psi particles. They see the expected spectrum of lines representing transitions to intermediate states between the first and second upsilon states (the upsilon-1S and the radially excited upsilon-2S). Their new observation is a line in the upsilon-1S decay spectrum corresponding to a transition to a novel 'zeta' particle with a mass of 8.3 GeV. If a Higgs particle exists, theory predicts it will associate most strongly with the heaviest of the other available particles. Thus, if the zeta particle is the Higgs particle, it should decay most commonly to a pair of the heaviest leptons, a tau and an antitau, and only rarely to a muon- or electron-pair. So far, however, taus have not been detected so there is no proof that the zeta is a Higgs particle. Moreover, the upsilon-2S also should decay into the Higgs particle and that has not been seen.

In the conventional picture, quantum chromodynamics (QCD) is the force which confines quarks and gives rise to the properties of the strongly interacting particles (hadrons). Before it can be proved, QCD needs to make a clear and specific prediction that can be tested. One such prediction is the existence of 'glueballs', particles which would have strong interactions but contain no quarks. Candidates exist, and the evidence is consistent with their being composed only of the self-interacting quanta of the QCD field, the vector gluons. In reviewing the subject, A.M. Zaitsev (Dubna, USSR) suggested that the theta-meson, seen in J/psi decay by the Mark III collaboration at Stanford, is most likely to be composed of gluons, but no one has been able to prove it.

Another explicit test may still be possible in photon–photon scattering, though theorists last year were despairing at infinities in the higher-order QCD calculations. Now Gluck, Grassie, Reya and Rossi, as reported by S. Brodsky (California Institute of Technology), have shown how to avoid these troubles. Experimenters are not surprised, since the data from PETRA and PEP already looked very close to the lowest-order QCD predictions. In fact, QCD looks increasingly satisfactory, even without a firm proof, just because it can be made to work without special pleading for such a wide range of processes.

The most memorable talk at the conference came from the speaker furthest removed from laboratory science, the Russian cosmologist A.D. Linde (Moscow). He displayed a breathtaking lucidity in dealing with the most complex of topics, 'inflationary models' of the early Universe. In his picture of the big bang, the first stage may be a quantum tunnelling from 'nothing'. In the very first moment of its existence, the Universe cannot have had a precisely defined energy, according to the Heisenberg uncertainty principle. It cannot therefore have been in the most stable possible state, and must have taken a while to stabilize, during which time expansion would start. According to Linde, this initial expansion is sufficient to 'explain' the isotropy of our visible Universe, together with its great asymmetry between particles and antiparticles. For 'explanation' he gave an impressive succession of arguments based on supersymmetry and other current speculative elementary particle theory.

The cosmologists are no longer as pleased as they were with one concept they inherited from particle theory — the possibility that neutrinos have mass, and therefore might account for the unseen mass of the Universe. Now they would rather that the unseen mass be carried by some of the hypothetical supersymmetric particles. M. Srednicki suggested that decay of these particles might account for the surprising number of antiprotons which have been observed in the cosmic radiation.

Terrestrial experimenters continue to look for the effects of finite-mass neutrinos. Two positive results were reported at the conference. B.A. Ljubimov (Novosibersk) reported an improved version of his group's earlier result on the end point of the β-decay spectrum of tritium. They obtain limits of between 20 and 45 eV for the mass of the neutrino produced in this decay. Of course, if a neutrino has mass, then it will not travel at the speed of light and the question of what happens in its rest-frame becomes relevant. One possibility is transitions between the three generations of neutrinos — the electron-, the muon- and the tau-neutrino. Searches have been going on for some years to establish the existence of such transitions, which might explain the continued shortfall in the number of solar neutrino interactions observed in the Brookhaven experiment of Davis and co-workers. A group working at the Le Bugey reactor in France reported evidence for the disappearance of neutrinos from their beam and gave a range of limits on the possible mass and transition rate which could cause this. But their result is incompatible over almost all of this range with an experiment at the Gösgen reactor in Switzerland, leaving only a tiny allowed region at a neutrino mass much lower than that measured by the Russian tritium experiment. Most observers are reserving their judgement on neutrino masses until some agreement is found between independent measurements. ☐

Geophysics

Open season for magmatic fractional crystallization

from Bob Thompson

PHASE-equilibria studies have for many years been a popular approach to studying the course of chemical evolution of a basic magma undergoing fractional crystallization. Analyses of volcanic rock suites suggest that a mildly-silica-undersaturated olivine–tholeiite magma may give rise to residues which are either Fe-rich and relatively Si-poor or vice-versa. On the basis of phase-equilibria data, P.L. Grove and M.B. Baker have recently proposed an ingenious mechanism whereby these alternatives may come about (*J. geophys. Res.* **89**, 3253; 1984).

They have made a detailed study of the crystallization of olivine–tholeiite melt at 1 atmosphere pressure, using electron-probe microanalysis to determine the compositions of all the solid and liquid (glass) phases. They find that when the liquids reach the stage of cotectic co-precipitation of plagioclase, olivine and Ca-rich clinopyroxene, the mineral assemblage shows a high ratio of the relatively siliceous phase, plagioclase, to the two ferromagnesian silicates, and relative Fe enrichment of the residue occurs. Enrichment is carried further when, with rising silica activity in the system, any crystals of olivine (a relatively Fe-rich and Si-poor phase) suspended in the liquid dissolve and are replaced by the Ca-poor clinopyroxene pigeonite.

Grove and Baker have not conducted experiments to elucidate the alternative so-called calc-alkaline fractionation trend towards Si enrichment and Fe depletion, but on the basis of published data, they propose that the key factors are crystallization of the magma under a moderate pressure (~ 5 kbar) and the presence of dissolved water in amounts less than sufficient to saturate the liquid. The field boundary between olivine and Ca-rich clinopyroxene is very sensitive to the first of these factors, whilst the second influences both the stability field and the composition of the precipitating feldspar. As a result, a hydrous (undersaturated) olivine–tholeiite magma fractionating at mid-crust depths may precipitate a high ratio of olivine and pyroxene to plagioclase, and the latter may be substantially more Ca-rich (and therefore Si-poor) than in the anhydrous system. The combination of these effects leads inexorably to siliceous Fe-poor residua.

The two fractionation schemes proposed by Grove and Baker may help to resolve a controversy which has rumbled along ever since Bowen produced a meticulously documented case that basic liquids proceed down the calc-alkaline trend during fractional crystallization (*The Evolution of the Igneous Rocks*, Princeton University Press; 1928), while Fenner showed in equally impressive detail that their chemistry evolved in an entirely different direction (*Mineral Mag.* **22**, 539; 1931). For many years attempts to reconcile these views focused on phase-equilibria experiments by Osborn and his co-workers (for example, *Am.J.Sci.* **264**, 428; 1966), who varied the oxidation states of Fe-bearing simplified basaltic systems and thus, by altering the proportion of magnetite to silicates in the precipitating phases, produced either Fe enrichment or Fe depletion. Grove and Baker accept the current widespread opinion that magnetite is an important phase separating during the later stages of fractional crystallization of basaltic melts, but that it is probably not a crucial trend-determining factor during the initial high-temperature stages. They take the same view of amphibole, another relatively Si-poor silicate, which has been canvassed by Green (in *Andesites*, Wiley, New York; 1982) and many others as the crucial phase to precipitate from a hydrous mafic magma and set it on a calc-alkaline trend, although Wyllie (*Phil.Trans.R.Soc.* **A310**, 439; 1984) has stressed that natural hydrous but undersaturated mafic liquids do not contain amphibole as a liquidus phase at the high temperatures of the basaltic composition range. Nonetheless, there seems to be incontrovertible petrographic evidence from xenoliths that amphibole precipitates with anorthite, magnesian olivine and Cr-rich diopsidic clinopyroxene from hydrous mafic liquids at depths corresponding to the crustal base in the island arcs of the Lesser Antilles (Arculus, R.J. & Wills, K.J.A. *J. Petrol.* **21**, 742; 1980), Aleutians (Conrad, W., Kay, R.W. & Kay, S.M. *J. Volcanol. geotherm. Res.* **18**, 279; 1983) and elsewhere. Perhaps, as Green suggests, the discrepancy between observational and experimental petrology is related to the fact that halogens in the natural systems would increase the thermal stability of amphibole.

Once removed from the pressures and temperatures at which they are stable, magmatic amphiboles dissolve rapidly. Their absence as phenocrysts from a suite of lavas is therefore probably no guarantee that amphibole was not fractionating at depth. Fortunately, the separation of this mineral leaves a distinctive imprint on the trace-element geochemistry of a suite of comagmatic rocks because the distribution coefficients of heavy rare-earth elements (HREE) between amphibole and mafic silicate liquids are so large that HREE concentrations fall with progressive fractional crystallization if amphibole is a major separating phase, whereas olivine, plagioclase and pyroxenes incorporate near-negligible amounts of HREE. REE data show the importance of amphibole separation in forcing basic magmas in the Aleutian Arc to follow calc-alkaline fractionation trends (Kay, S.M. *et al. J.geophys.Res.* **87**, 4051; 1982).

Grove and Baker use two subduction-related magmatic suites to illustrate their model for the genesis of calc-alkaline residua. In the oceanic example, the Witu Islands, Papua New Guinea, closed-system fractional crystallization can explain all the available chemical data for the lavas. By contrast, the continental margin suite — from Medicine Lake Highland volcano, California — shows increases in various trace elements and $^{87}Sr/^{86}Sr$ ratio with magmatic evolution that cannot result from closed-system processes and require an open-system model, with concomitant fractional crystallization and assimilation of small amounts of fused sialic crust. This type of scenario appeals to the authors of most recent detailed geochemical studies of magmatic provinces where large volumes of basic liquid have invaded continental crust over a short time span (for example, James, D.E. *Yb.Carnegie Inst. Wash.* **82**, 486; 1983; Cox, K.G. & Hawkesworth, C.J. *Phil. Trans. R.Soc.* **A310**, 627; 1984), although the details of the relationship between fractional crystallization and sial assimilation seem to vary from case to case (Thomson, R.N., Morrison, M.A., Dickin, A.P. & Hendry, G.L. in *Continental Basalts and Mantle Xenoliths*, Shiva Press; 1983). □

Grebes and Nest.

100 years ago

BRITISH BIRDS AT THE NATURAL HISTORY MUSEUM

VISITORS to the new Natural History Museum can scarcely have failed to notice the many improvements which have been made in the rearrangement of the zoology collections since their removal from Bloomsbury to South Kensington. Here the visitor finds a collection of British birds, in which each species is separately represented by a pair of old birds in the plumage peculiar to the breeding season, with its nest and eggs, not merely in a natural position, but in the actual position in which they were found.

Not very long since Mr. H. Seebohm gave a lecture at the Zoological Gardens on "Birds' Nests" From an attentive study of the subject he considered that nests might be roughly grouped into five classes, according as the birds which owned them relied for the safety of their eggs: (1) on the concealed position of the nest; (2) upon the inaccessible position of the nest; (3) upon the protective colour of the eggs; (4) upon the protective colour of the sitting hen; (5) upon their own ability, either singly, in pairs or in colonies to defend their eggs.

Amongst birds which rely for safety on the inaccessible position of their nest may be mentioned the hawks and owls, raven, chough, kingfisher, sandmartin, moorhen, coot, and grebe. There are few eggs more difficult to take than those of the peregrine falcon, raven, and chough, from the habit of these birds to nest in precipitous cliffs; while moorhens, coots, and grebes, make slovenly-constructed nests upon soft, treacherous ground, or amongst sedges, flags, and other water plants which are unapproachable without the aid of a boat. One cannot fail to note that the more slovenly the nest of these water-birds the more likely is it to escape detection, for, were it well shaped and neat in appearance, its very neatness amidst a mass of wind-strewn rushes or tangled growth of water-weeds would be sure to attract attention towards it.

Cell biology

First clue to biological role of clathrin light chains

21.1.87
A. Baltz

from Ernst Ungewickell

Two papers[1,2] in this week's *Nature* shed new light on the nature and mechanism of action of coated pits and coated vesicles, two related cell organelles responsible for selective ingestion and specific intracellular transport of membrane proteins by eukaryotic cells[3].

We now know a good deal about the structure of these apparatuses. Their cytoplasmic sides are coated by polyhedal constructions, made up of clathrin (molecular weight 180,000) and several associated polypeptides with subunit molecular weights of 100,000 - 130,000, ~ 50,000 and 30,000–40,000. The building blocks or protomers of the coats are three-legged complexes commonly referred to as clathrin triskelions, constructed from three 180K polypeptide chains. Tightly associated with the triskelions are three of the 30K–40K polypeptides, usually referred to as clathrin light chains or sometimes clathrin-associated proteins (CAPs). Each vertex in the polyhedral coat structure is the centre of a triskelion and the edges of the polygons are formed by extensively overlapping legs of adjoining triskelions (for details see ref. 4).

Both coated pits and coated vesicles are highly dynamic structures. According to a widely accepted working hypothesis the latter derive from the former by a kind of budding process that is accompanied by a rearrangement of the coat structure, whereby some hexagonal facets turn into pentagons so that the polyhedra then possess twelve pentagonal faces amongst the hexagons. Upon budding, coated vesicles rapidly shed their coats to allow them to fuse with their target membranes. The liberated triskelions are thought to return to the membrane to reassociate with an incipient coated pit. This cycle requires a sophisticated regulatory mechanism that must orchestrate assembly, disassembly and reorganization of the coat structure.

Two years ago Patzer *et al.* discovered in the cytosol from bovine brains a protein factor, which in the presence of ATP was able to strip coated vesicles of their coats[5]. The same group has now purified this factor almost to homogeneity by a sequence of steps, of which the most important is affinity chromatography on coupled ATP[6].

This 70K protein turns out to have a latent ATPase activity, which is activated by coated vesicles or indeed by the empty cage-like structures generated by purified triskelions. In ionic milieus, in which the clathrin polyhedron is marginally unstable, the factor causes dissociation of the vesicle coat or disruption of the empty cage, with formation of a complex that contains one molecule of factor per triskelion leg. The triskelions thus sequestered will not reassociate to cages, even under the most favourable ionic conditions.

A recent exciting extension of this work, reported on page 228 of this issue of *Nature*, is the demonstration that the presence of clathrin light chains on the assembled triskelions is a prerequisite for the interaction of the uncoating protein with clathrin and hence for the expression of ATPase activity, and disintegration of the structure into triskelions[1]. Neither free triskelions with bound light chains nor free light chains alone are recognized by the uncoating protein. This result gives us the first indication of a biological role for clathrin light chains.

The mechanistic details of the uncoating reaction remain to be elucidated. The observation that factor-dependent uncoating is most effective under conditions in which cages or coats are not very stable suggests that the action of the uncoating protein is contingent on the prior dissociation of interacting triskelion legs. Normally, a single transient dissociation event has no ill-effects, for the two remaining legs of the triskelion will suffice to hold it securely in place. As judged by electron microscopy[6], the uncoating protein seems to bind near the centre of the triskelion, yet it evidently disrupts a clathrin–clathrin interaction that extends over 18 nm or so. It is here that the light chains may intervene, since they have been shown to extend from the triskelion centre to a point at least 16 nm along the leg[7]. It may be conjectured, then, that binding of uncoating protein and concomitant ATP hydrolysis induces a conformational change in the light chains or a change in their binding site on the heavy chain, such that when two legs dissociate, they will no longer recombine. The dissociation of the last of the three legs of a given triskelion will then result in its release from the cage. In order to restore the ability of the liberated triskelions to enter into a new round of coating and uncoating, other, as yet unrecognized factors may be required.

But to denude coated vesicles of their coats it is not sufficient merely to impede clathrin–clathrin interactions, since triskelions are also anchored by way of protease-sensitive sites to the vesicle membrane itself. For the present it is not altogether clear whether this interaction is also perturbed by the uncoating protein or whether release of triskelions from the membrane involves two unrelated, but simultaneous events.

In this connection one should take note of the intriguing results of Pauloin *et al.*[8], concerning a coated vesicle-associated Ca^{2+}- and cyclic AMP-independent protein kinase that phosphorylates specifically a 50K polypeptide in coated vesicles. This group has now shown (see page 265) that after extraction of purified coated vesicles with 0.5 M Tris, the 50K substrate co-elutes from gel-filtration columns together with the 100K - 130K polypeptide cluster. This fraction also contains the kinase activity. Chemical cross-linking experiments support the idea of a stoichiometric interaction between the 50K phosphoprotein and probably a single member of the 100K–130K subunit group. Even before this finding, there were reasons enough for homing in on this polypeptide mixture, since Zaremba and Keen have shown that it promotes the self-association of purified clathrin triskelions into a relatively uniform population of 78 nm cages, under conditions that otherwise prohibit assembly[9]. Furthermore, some of these polypeptides are suspected to mediate the interaction of clathrin with the coated vesicle membrane[10].

When Pauloin and Jollès[2] investigated the effect of purified triskelions on the kinase activity, they noted a fourfold stimulation, which they were able to ascribe uniquely to the clathrin light chains.

The conditions employed for the phosphorylation of the 50K polypeptide are similar to those in the uncoating experiments of the Stanford group and one should therefore expect both events to occur simultaneously (though the sceptical reader may feel a trifle uneasy at the low ionic strength of the media preferred by both groups). It would be pleasing if it should turn out that the phosphorylation of the 50K polypeptides weakens the interaction of triskelions with the membrane, but this is perhaps too much to hope for at this stage.

Nevertheless, I would expect that the undoubted breakthrough by Rothman and his group on the uncoating reaction will provoke some workers in the field to leap onto the accelerating bandwagon before its speed becomes dangerously high. At all events, further rapid progress in uncovering the details of the coated pit/coated vesicle pathway can be confidently predicted. □

Developmental biology

How to make a fruitfly

from Geoffrey North

In recent issues of *Nature*, Gary Struhl[1] and Jonathan Slack[2] have explained how the discovery of the 'homoeo box' may have provided the first link between genes known to regulate the development of the fruitfly *Drosophila melanogaster* and previously unknown sets of analogous genes in vertebrates. The 'homoeo box' is a short DNA sequence present in several of the homoeotic genes that specify the character of the different parts of the fruitfly body[3,4] and it has now turned up in a highly conserved form in the genomes of vertebrates[5,6].

If the promise of this startling discovery is fulfilled, the great gap that has separated the genetic understanding of *Drosophila* development from that of the higher vertebrates will soon begin to close. In the meantime, as became clear at a recent meeting*, it continues to widen rapidly. Nearly all of the genes concerned with regulating the early development of *Drosophila* will soon have been identified, while the analysis of the later-acting homoeotic genes has already reached the stage at which their protein products are coming in for scrutiny.

Establishing polarity

The earliest genes involved in regulating embryonic development are those that determine the polarity of the three axes of the embryo: anterior–posterior, dorsal–ventral and left–right. These genes are defined by mutations that affect the establishment of pattern along one axis independently of the others, and establish polarity of the egg even before fertilization; thus their effects on the embryo reflect only the maternal genotype and mutations in these genes are known as 'maternal-effect' mutations.

The establishment of the dorsal–ventral polarity has been studied in most detail. The prototype gene affecting this polarity is called *dorsal*, and females homozygous for the most extreme *dorsal* mutations produce what are known as 'dorsalized' embryos, which lack ventral and lateral structures, and have dorsal structures extending all around the body. Weaker *dorsal* mutations allow the development of more lateral structures, which is consistent with the existence of a gradient of some morphogen that determines polarity.

A total of eleven genes, recessive mutations of which have effects identical to that of *dorsal*, has now been identified (K. Anderson, Friedrich-Miescher Laboratorium, Tübingen). The implication is that each of these genes, which are distributed throughout the genome of *Drosophila*, encodes a component of a unified process of pattern formation. According to recent evidence reported by Anderson, the component contributed by one of them, a gene named *Toll*, may actually be a physiological morphogen.

As with the other ten genes, recessive mutations in *Toll* cause 'dorsalized' embryos. But dominant mutations in the same gene produce the reverse effect: the extension of ventral structures to the dorsal side of the embryo. And females that not only have a dominant *Toll* allele, but are also homozygous for mutations of all but *dorsal* itself of the ten other genes, produce 'lateralized' embryos, which lack structures characteristic of the dorsal-most and ventral-most regions of the embryo.

The evidence that *Toll* encodes a morphogen comes from experiments in which components of wild-type embryos are injected into mutant embryos. Some of the recessive dorsalized mutants, including *Toll*, can be rescued by injections of wild-type cytoplasm into the embryo (ref. 7 and Anderson). But only in the case of *Toll* can the polarity of the embryo be reversed by such injections. In mutant embryos the egg retains a visible dorsal–ventral asymmetry, even when the embryo into which it eventually develops does not. In all 'rescue' cases other than *Toll*, the rescued embryo has the same polarity as the egg. This shows that these mutant embryos must retain an intrinsic polarity that can be expressed only in the presence of some factor in the wild-type cytoplasm. In the case of *Toll*, however, the polarity of the rescued embryo is determined by the site of injection of the wild-type cytoplasm. The implication is that unlike the other dorsalized mutants, recessive *Toll* mutant embryos really are apolar, and that the product of the *Toll* gene, by its differential localization in the embryo, is a direct determinant of dorsal–ventral polarity. A possible explanation of the dominant 'ventralizing' *Toll* alleles, then, might be that they result in the overproduction of the *Toll* gene product, so that levels are elevated in more dorsal regions of the embryo leading to the determination of ventral structures in the wrong place.

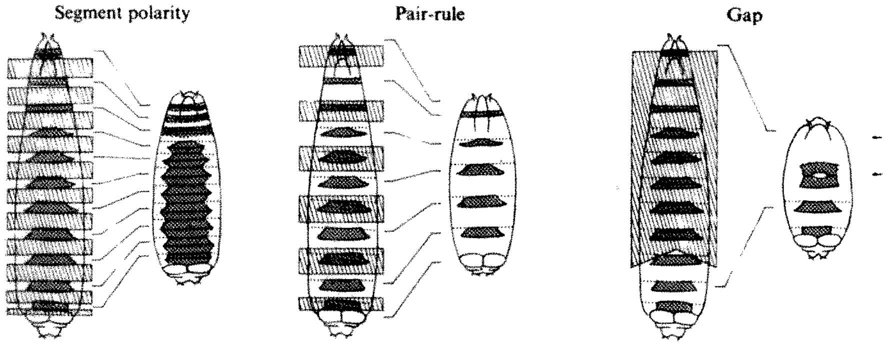
In this issue of *Nature*, two papers report further important steps in understanding the molecular nature of the mother fruitfly's legacy to its offspring. On page 223, Christiane Nüsslein-Volhard and Anderson show that for many of the genes involved in establishing dorsal–ventral polarity, a substantial fraction of the rescuing activity is in the form of stored maternal poly(A)$^+$ RNA[8]. And the cloning of the first of these genes, *dorsal*, together with evidence that the gene encodes a 2.8 kilobase (kb) RNA present in ovaries and 0–2.5 h embryos, is reported by Steward *et al.*[9] on page 262.

Dividing up the embryo

Apart from its overall symmetry and polarities, the other obvious feature of the body of a fruitfly is that it is divided into segments along its anterior–posterior axis. Segmental patterns have fascinated theoreticians of pattern formation for many years, but the mechanistic basis of the periodicity they imply has remained elusive. This may change with the characterization of the genes controlling segmentation of *Drosophila*.

In 1980, Nüsslein-Volhard and Wieschaus reported the identification of fifteen genes, mutations of which caused an alteration of the segmental pattern of homozygous larvae[10]. The mutations fall into three classes, defined by the kind of pattern alteration they cause (see the figure). Two of the classes have a periodic effect on the segmental pattern, one with a periodicity of a single segment (segment polarity mutations), the other with a two-segment periodicity (pair-rule mutations). Mutations of the third class (gap mutations) have an aperiodic effect, causing the loss of groups of adjacent segments.

Of the three classes, the gap genes are thought likely to work the earliest in development, possibly having a primary role in interpreting an anterior–posterior gradient of positional information and determining large regions of the early



One example of each of the three classes of *Drosophila* mutations which alter the segmented pattern of homozygous larvae. The hatched bars on the normal larvae (left) indicate the regions missing in the mutant larvae (right). From ref. 10.

---

*The fourth EMBO Workshop on the molecular and developmental biology of *Drosophila* was held in the Orthodox Academy of Kolymbari, Crete, from 24 to 29 June 1984.

embryo (H. Meinhardt, Max Planck Institut fur Entwicklungsbiologie, Tübingen). There are three zygotic gap genes, which differ with respect to the region of the embryo affected by mutations of them: *hunchback* mutations delete thoracic segments; *knirps* mutations delete abdominal segments; and *Krüppel* mutations delete thoracic and anterior abdominal segments. It seems that in the absence of the appropriate gap gene, large regions of the embryo simply fail to develop, the remaining segments developing normally. Further insight into their workings should be forthcoming, now that the *Krüppel* gene has been cloned (H. Jäckle, Max Planck Institut fur Entwicklungsbiologie, Tübingen). The partial rescue of mutant embryos by injecting the cloned DNA into the prospective thoracic and anterior abdominal region suggests that the product of the *Krüppel* gene is active in the region of the embryo affected by *Krüppel* mutations. The major RNA transcript detected by hybridization with the cloned *Krüppel* DNA is expressed specifically at the blastoderm stage of development, which is the time when the *Krüppel* gene product seems to be required.

By the time that signs of segmentation first become apparent in the life of a fruitfly, the embryo's nuclei have become transcriptionally active and its development is no longer dominated by its maternal inheritance. However, although most of the segmentation genes are strictly zygotic, several of the *knirps* group of gap genes, including *oskar*, are actually maternal-effect genes. Nüsslein-Volhard (Friedrich-Miescher Laboratorium, Tübingen) reported that the phenotype of *oskar* mutant embryos (which would normally fail to develop an abdomen) can be completely rescued by the injection of wild-type cytoplasm as long as the cytoplasm is taken from the posterior pole of a wild-type embryo and injected into the prospective abdominal region of the mutant embryo. The implication is that the rescuing activity is actually stored at the posterior pole and transported anteriorly, in some way influencing the development of cells in the abdominal region of the embryo.

Of the genes that have a periodic effect on the segmentation pattern when mutated, most is known of the pair-rule gene *fushi tarazu* (*ftz*). In homozygous *ftz* mutant embryos, roughly the posterior half of every even-numbered segment and the anterior half of every odd-numbered segment is deleted; the remaining half-segments are fused, so that the mutant embryos have half the usual number of segments. Interestingly, in normal embryos, *ftz* RNA is distributed periodically, with a periodicity roughly corresponding to that of the deleted parts of *ftz* mutant embryos, before the first morphological signs of segmentation (A. Kuraiwa, Biozentrium, Basel; refs 2, 11, 12).

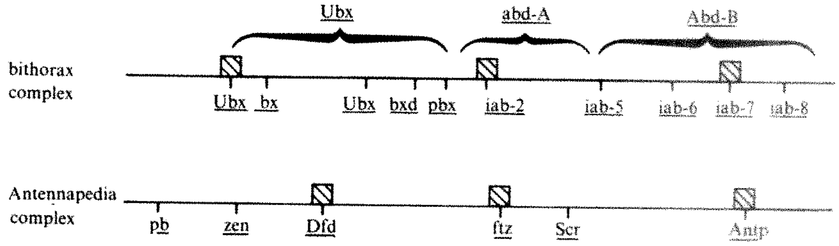
Another pair-rule gene, *Hairy*, seems to be the complement of *ftz* in that *Hairy* mutations lead to the deletion of the parts not deleted in *ftz* mutants. An important point made by D. Ish-Horowicz (Imperial Cancer Research Fund, London) is that the parts of the embryo not deleted in *Hairy* mutants retain their wild-type segment identity. By combining *Hairy* and homoeotic mutations it has also been shown that the requirement for a wild-type *Hairy* gene depends upon the position of a group of cells in the embryo, and not upon the character of the segment of which the cells will form a part. So it would seem that segment specification — the domain of the homoeotic genes — and whatever genes such as *ftz* and *Hairy* are doing, are to some extent independent processes. Ish-Horowicz revealed that the *Hairy* gene has been cloned and shown to be expressed early in development, so it will be interesting to see how the spatial distribution of *Hairy* transcripts compares with that of *ftz* transcripts.

Homoeo box latest

Walter Gehring revealed at the European Developmental Biology Congress in Southampton two weeks ago that his group in Basle, in collaboration with Tom Kornberg in San Francisco, has now identified the first gene in *Drosophila* outside of the bithorax and Antennapedia complexes to contain a homoeo box sequence. The gene is ***engrailed***, which keeps up the association of the homoeo box with genes that specify the development of different parts of the fruitfly as *engrailed* is also a homoeotic gene, with the particular role of distinguishing the posterior from the anterior compartments of each segment. Gehring also reported that it is now clear that at least nine homoeo boxes fall within the bithorax and Antennapedia complexes: three have been mapped within the bithorax complex (two by Welcome Bender's group at Harvard), and there are at least six in the Antennapedia complex, of which three have been assigned to known genes (see the figure; note that further genes are believed to exist within Antennapedia, left of *pb*).

The disposition of the three homoeo boxes within the bithorax complex may be especially significant in the light of some recent results of Gines Morata (University of Madrid). Morata reported at the Crete meeting that on the basis of complementation analyses the bithorax complex seems to consist of three distinct genes: *Ultrabithorax* (*Ubx*), *abdominal-A* (*abd-A*) and *Abdominal-B* (*Abd-B*). Each of these genes is concerned with specifying the development of a different region of the fruitfly: thus, the *Ubx* domain extends from the posterior compartment of the second thoracic segment to the anterior compartment of the first abdominal segment; the *abd-A* gene then takes over as far as the fourth abdominal segment; and the *Abd-B* gene specifies the four most posterior segments. As can be seen in the figure, the three homoeo boxes have fallen neatly one into each genetically defined unit.

Although evidence is still lacking that the highly-conserved homoeo box sequences that have been found in the genomes of vertebrates really are markers of genes involved in regulating development, the assumption has now received further support from the first studies of the expression of such a gene. The crucial finding reported by Eddy de Robertis (Basle) in Southampton is that the second homoeo box-containing gene his group has identified in the genome of the frog *Xenopus laevis* is expressed at high levels in oocytes, and that transcripts of the gene disappear in early (blastula-phase) embryos. Transcripts of the gene can again be detected at gastrulation, but at a much lower level than in oocytes. The exciting possibility suggested by these observations is that they have identified a gene that encodes a stored maternal mRNA that may be involved in specifying the early development of the frog embryo.



Specifying the parts

The importance as units of development of the parts into which segmentation divides the body of a fruitfly is clearly shown by the effects of homoeotic mutations, which cause specific parts of the body to develop in ways characteristic of other parts. The affected parts are usually delineated by either two segment boundaries, or a segment boundary and a line that divides a segment into anterior and posterior halves. Homoeotic mutations are thought to identify genes that specify the development of different parts of a fruitfly's body, and their domains of action are known as developmental compartments.

The archetypal homoeotic genes cluster in a region of the *Drosophila* genome known as the bithorax complex, which controls the development of all segments of the *Drosophila* body posterior to the second thoracic segments. Recessive bithorax complex mutations cause segments to develop like more anterior segments, and the genetic order of the mutants roughly corresponds to the spatial order of the affected segments along the anterior–posterior axis[13].

These observations led E.B. Lewis of the California Institute of Technology to propose that, starting with the third thoracic segment, progressively more posterior segments express successively more of the genetic components of the bithorax complex, and that the particular combination of genes expressed by groups of cells early in development is determined by their position in the embryo and directs their subsequent developmental fate. The conceptual framework established by Lewis (and elaborated by others, see ref. 14) has become open to direct testing at the molecular level with the recent cloning of bithorax[15]. This cloning feat has also helped to suggest an explanation for the intriguing genetic phenomenon of *cis*-vection, which was the topic of Lewis's talk in Crete and may turn out to be a reflection of an important aspect of the regulation of expression of bithorax complex genes.

Cis-vection in the bithorax complex is seen in the case of *Ultrabithorax* (*Ubx*) mutations. These mutations are capable of inactivating simultaneously four independent activities mapping in the bithorax complex, each of which is primarily concerned with specifying a different one of the four half-segments from posterior second thoracic to anterior first abdominal. *Ubx* mutations are thus like the sum of the four mutations ***anteriorbithorax*** (***abx***), ***bithorax*** (***bx***), ***postbithorax*** (***pbx***) and ***bithoraxoid*** (***bxd***), each of which transforms one of the four half-segments into the equivalent half-segment of the immediately preceding segment. *Ubx*, *abx* and *bx* mutations all map together in a segment of the bithorax complex which is known to encode a giant 75 kb primary transcript that is processed into several discrete RNA products[3].

Thus the effect of *Ubx* mutations on the activities of *abx* and *bx* functions is relatively easy to explain: either *abx* or *bx* are discretely inactivated by point mutations or both are abolished by a mutation (*Ubx*) affecting the entire unit. *Pbx* and *bxd* mutations, however, map within a separate 25 kb (*bxd*) transcription unit upstream of the *Ubx* transciption unit and which also encodes multiple RNA products. How, then, is the effect of *Ubx* mutations on *pbx* and *bxd* functions to be explained? This is the problem of *cis*-vection, and D. Hogness (Stanford University) and P. O'Farrell (University of California, San Fransisco) independently suggested the following solution.

Although mutations that independently affect the *pbx* and *bxd* functions map to the *bxd* transcription unit, Hogness and O'Farrell suggest that the gene products are encoded, together with the *abx* and *bx* products, in the discrete RNAs produced from the *Ubx* transcription unit. To account for *cis*-vection Hogness and O'Farrell suggest that the *Ubx* and *bxd* primary transcripts interact whilst still attached to the chromosome, and that the interaction is required for correct processing of the *Ubx* transcript to produce the RNAs specifying the four *Ubx* activities. Consistent with this model is the lack of sizeable open reading frames in the sequences of cDNA copies of *bxd* transcripts so far determined by Hogness's group. Although no clear relationship has yet been established between a *Ubx* function and a *Ubx* transcript, the 4.7 kb size class *Ubx* RNA is present only early in development (Hogness), which suggests it may be associated with the *abx* function that has been shown by clonal analysis to be a uniquely early *Ubx* activity (the others are required throughout larval development).

To return to Lewis's model for the bithorax complex, the crucial prediction that has become amenable to testing is that the genes are expressed in a segment-specific fashion. Akam has shown by the technique of hybridization *in situ* that *Ubx* RNAs are indeed expressed only in specific segments of *Drosophila* embryos and larvae, and that, by and large, the highest levels of expression occur in those regions most affected by *Ubx* mutations[16]. But Akam's results extend the conclusions drawn from classical genetic experiments in two important respects. The first is that the spatial pattern of expression actually does differ for different cell types: for example, in larvae the pattern for epidermal cells differs from that for muscle cells. The second is that it is now clear that Lewis's original suggestion that bithorax genes are expressed in all segments posterior of the first segment in which they are expressed is oversimplistic: for example, in embryos the level of *Ubx* expression in central nervous system cells decreases posterior of the first abdominal segment.

Two speakers in Crete, Hogness and R. White (Laboratory of Molecular Biology, Cambridge), reported that the availability of cloned DNA has for the first time allowed the protein products of a homoeotic gene to be identified and localized in a developing fruitfly. The results presented by both speakers relied on antibodies generated against hybrid proteins made by expressing *Ubx* cDNA sequences fused to a β-galactosidase gene in *Escherichia coli*. From what is known of the processing of *Ubx* RNAs the antigenic determinants recognized by the antibodies could be shared by several different protein products, and in fact White has found by protein-blotting experiments that his antibodies recognize at least three proteins, two of molecular weights of approximately 44,000 and one of 41,000.

Both Hogness and White reported immunofluorescence staining experiments carried out to localize the *Ubx* proteins in wild-type and mutant embryos and larvae. An important observation made by both groups is that the proteins are localized in cell nuclei, which is consistent with the suggestion that they have DNA-binding activities, conferred by the basic 'homoeo box' domain[1,17,18].

The distribution of *Ubx* proteins in wild-type embryos and larvae is reasonably consistent with that reported for the RNAs by Akam. However, further complications of the classical model of the bithorax complex have been revealed by the effects of mutations on the distribution. Thus, Hogness reported that mutations of the *Polycomb* gene, which transform all segments into copies of the most posterior abdominal segment, do indeed make all segments stain like the most posterior abdominal segment of wild-type embryos. But this means that in the third thoracic and first abdominal segments the level of *Ubx* proteins actually appears to decrease, in direct contradiction of Lewis's prediction that *Polycomb* mutations simply deregulate bithorax gene expression so that all genes are expressed in all segments.

I think it is fair to say that in general terms Lewis's model is proving remarkably valid. Not surprisingly, the details are proving more complex than can have been predicted solely on the basis of classical genetic experiments, and the hope now is that some of this complexity will become unravelled when the relationship between the multiple mRNA and protein products of the bithorax complex genes and the genetically identified activities becomes clearer.

Caveat

Lest some might infer from the above that developmental biology is close to being solved, I think I should say that even now not a single process of pattern formation in *Drosophila* is understood in mechanistic detail. The position is somewhat akin to that in the study of the molecular basis of cancer: many of the genes involved are known, but how they work is poorly understood.

To take just one example, virtually nothing is known of the origins of asymmetry in the embryo. As I have explained above these origins seem the domain of maternal genes expressed during oogenesis, but it is an open question whether the asymmetries inherent in a *Drosophila* egg are determined explicitly by the asymmetrical nature of meiosis, or are generated *de novo* by the maternal gene products during egg development.

Perhaps the most important conclusion is that the problems can now be seen to be soluble. In the end, we shall know how fruitflies are made. And perhaps, when we do, we shall know in principle how people are made too. □

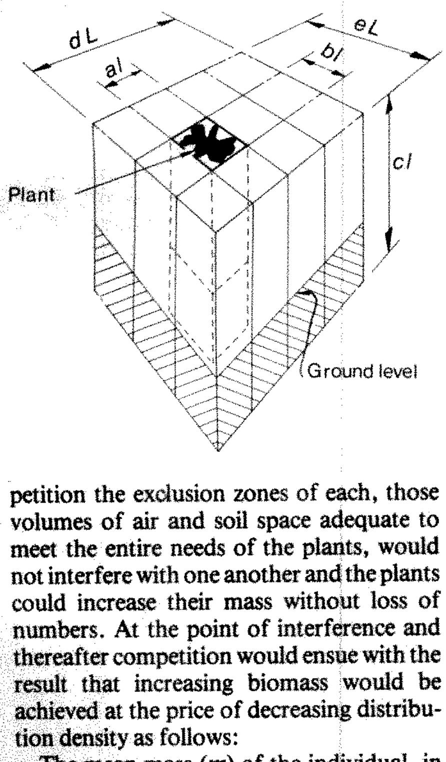
Laying down the $-3/2$ power law

SIR — Referring to the ecological -3/2 power law, A.F. Hayton[1] mentions White's belief[2] that the ecological "-3/2 law" has not yet been properly explained. The background to the law is indeed traceable to the Japanese origins[3-5] referred to by Hayton. There its attempted explanation is seen to revolve around the consideration of energetics, the energy flux transferring through the surface of a plant to contribute to the energy encapsulated within its volume. Dimensionally these relate to each other according to the square and cube respectively of a typical dimension. In the form of the "-3/2 law" this reduces to the now-famous gradient. However, reservations regarding rigour persist primarily it would appear because mixing the area of the individual plant surface with that of the territory colonized by the whole population threatens to cloud the issue.

Let us instead explore a purely geometric analysis. The figure represents a plant growing within a population of N individuals occupying a territory of area A. Prior to competition the exclusion zones of each, those volumes of air and soil space adequate to meet the entire needs of the plants, would not interfere with one another and the plants could increase their mass without loss of numbers. At the point of interference and thereafter competition would ensue with the result that increasing biomass would be achieved at the price of decreasing distribution density as follows:



The mean mass (m) of the individual, in this case the typical specimen shown in the figure, is $\varrho\, x\, (al)\, (bl)\, (cl)$ in which ϱ is the density of the plant x is the proportion of the space occupied by the plant within its exclusion zone, l is a typical dimension of the plant and, a, b and c are constants for a particular genera relating the plant to its exclusion zone; a would normally be equal to be in this schematic representation.

Thus we have:

$$m = \varrho\, xabc\, l^3 = kl^3 = k\left(\frac{1}{l_2}\right)^{-3/2} = k\left(\frac{N}{Nl^2}\right)^{-3/2}$$

where $k = \varrho\, xabc$, a combination of constants for a particular genera.

Also, if L is a typical dimension of the total territory occupied by the whole population, the area (A) of that territory is $(dL)\,(eL)$ where d and e are constants determining the shape of the area in this schematic representation. However, in a competing community of N individuals $N\,(al)\,(bl) = (dL)\,(eL)$. Therefore, $Nl^2 = (de/ab)L^2$. Hence:

$$m = k\left(\frac{abN}{deL^2}\right)^{-3/2} = k\,(ab)^{-3/2}\left(\frac{N}{deL^2}\right)^{-3/2}$$

$= K\left(\frac{N}{A}\right)^{-3/2}$ where K is a derived constant for a particular genera.

Therefore, $\log m = -3/2 \log\left(\frac{N}{A}\right) + \log K$

This is the "-3/2 law". Its derivation thus far requires no significant reference to energetics, although any attempt to quantify K would, as it contains ϱ, x, a, b and c, all of which are to some degree genera-dependent with x in particular almost certainly relating to energetics. However, the basic law is a geometrical phenomenon and perhaps now deserves to be regarded as a true law instead of the mere rule correctly noted by Hayton in relation to previous usage.

A final point, the "-3/2 law" relates the distribution density to the *mean* mass and not the *combined* biomass, as implied by Hayton, although in the context of the above item, in which nations of people are considered as separate units of biomass and treated individually, this does not devalue its contribution.

Repetitive sequences in structural genes

SIR — In a recent News and Views item[1], Edward Max discusses the implications of CpG clusters in structural genes. He postulates that these CpG clusters will be under-methylated in germ-line DNA and proposes the experiment of determining whether the CpG-rich regions of histocompatibility Class I genes will be found to be under-methylated in sperm DNA. Our recent study in mouse sperm DNA of the state of methylation of *H-2*, Class I CpG sequences recognized by the isoschizomers *Msp* I and *Hpa* II showed them to be highly methylated. The multiplicity of sequences cross-hybridizing to the Class I probe prevents us from determining the 3′ or 5′ location of the few unmethylated sites. The other sequences studied (β-globin, amylase, and a spermatid cDNA clone) were also highly methylated in germ-line DNA, even from immature testes which contain only pre-meiotic cells.

These results are comparable to those reported by others who have found that structural genes are usually highly methylated in sperm DNA (rabbit β-globin[3], ovalbumin[4], α2-collagen[5]). In contrast, those repetitive sequences which have been studied were found to be hypomethylated in sperm DNA[6-8]. Since the two classes of sequences behave differently at meiosis, the alterations in methylation seen in sperm DNA are unlikely to be secondary to the chromatin structure changes which occur during meiosis.

Fourier's law and thermal conduction

SIR — Casati *et al.*[1] recently described a many-body system in which the Fourier law for thermal conductivity was shown to result from the deterministically random dynamics of the system. Their conclusions are interesting, and confirm and extend similar results that were found for another one-dimensional system a year ago[2]. In an editorial comment[3] the importance of the results of ref.1 were correctly described, but again there was no reference to our earlier work. We now wish to discuss the numerical calculations which have been done for the diatomic Toda chain, and to outline some of the outstanding problems in this field.

The diatomic Toda lattice is a linear chain with alternating masses which interact by an exponential force[2,4]. The equations of motion for the displacement q_n and the momentum p_n at site n for the mass ratio $\sigma_{2n} = \sigma$ and $\sigma_{2n+1} = 1$ can be written down as:

$$\begin{aligned} dp_n/dt &= \exp(q_{n-1} - q_n) - \exp(q_n - q_{n+1}) \\ dq_n/dt &= \sigma_n V p_n \end{aligned}$$

For equal masses ($\sigma = 1$) this is one of the few discrete lattices which are integrable[5]. For alternating masses the system is not integrable[6] but shows mixing behaviour[2,6].

This diatomic Toda chain was coupled at both ends to two different heat baths containing particles with a maxwellian distribution with which the first as well as the last particle in the chain can exchange momentum by a realistic collision mechanism[7]. The conductivity coefficient was shown to depend on the mass ratio and temperature of the heat bath, but most importantly, it was independent of the chain length and therefore an intrinsic property of the chain. The results in ref.2 are calculated for quite large mass-differences. For the case of only small mass differences the influence of the non-integrability is not strong enough and additional heat transport is possible via slowly decaying solitary excitations.

This effect is most dramatically seen in the case of the monatomic chain where the mean kinetic energy of the particles is constant along the chain. At larger mass-differences, however, and when the heat baths are at high temperatures, there was no influence of solitary transport in the heat current. As well as studying the current through the first particle, we examined the difference of the current through the first and the last particle. This difference became equal to zero with small oscillations after a certain time of integration. Comparisons with experimental values for the conductivity were quite satisfactory. Interestingly, in all our computer-experiments we found a certain surface layer with rather high thermal resistivity.

Both systems[1,2] are coupled to the randomly acting heat baths and therefore the dynamical system itself is only a transport mechanism to these random collisions. It would be very interesting (but much more complicated) to study the behavior of the diatomic Toda chain in phase space without external disturbances. Preliminary results indicate that the system starting from an arbitrary state relaxes to a state with equally distributed kinetic energy, it behaves like a thermodynamical system. But again one has to be very careful in studying this effect since another random influence, namely the numerical errors in the computational procedure, may change the conclusions. It would therefore be desirable to have some analytic results on these systems that can be compared to studies in which thermal conduction is studied in a system of oscillators interacting by a stochastic process[8].

Finally, it should be noted that the two systems so far studied are one-dimensional and the influence of higher dimensions remains to be determined[9]. It is known that in higher dimensions solitary excitations decay much more rapidly and this might help the normal thermal conduction; but numerical computer experiments in this case need much larger computers than we have available.

In summary, we think that some progress has been made in interpreting Fourier's law for thermal conduction. But it is worth remembering Peierls comment in 1960: "It seems there is no problem in modern physics for which there are on record as many false starts and as many theories which overlook some essential features as in the problem of thermal conductivity of non-conducting crystals"[10].

On the hand of *Archaeopteryx*

SIR — Hecht and Tarsitano[1] complain that Howgate[2] has misrepresented their views[3,4] on the structure of the hand in *Archaeopteryx*. Howgate also discussed our interpretation of the *Archaeopteryx* hand[5], yet we find that his inaccuracies are trivial when measured against those of Hecht and Tarsitano.

According to Hecht and Tarsitano[1], palaeontologists unfailingly identify the three hand digits of theropods, *Archaeopteryx* and birds as numbers 1-2-3 (relative to a primitive pentadactyl format). Indeed, they maintain that palaeontologists are "convinced" of this fact in *Archaeopteryx*. This is not entirely true, for we have argued[5] that the digits are numbers 2-3-4. Hecht and Tarsitano are certainly aware of our arguments because they have cited them in their published work[4]. Yet on this occasion[1], in chiding Howgate, they chose to overlook such irksome details. In fact we are justified in claiming that Hecht and Tarsitano have misrepresented our views. We suggested[5] that the longest metacarpal should be identified as number 3 — and not the longest *digit*, as was stated by Hecht and Tarsitano[4]. However, this part of our argument, along with the rest, was dismissed by these authors as "merely changing the numbering of the digits".

Next, Hecht and Tarsitano plead that they "only stated the possibility" of there being a break in the outermost finger of the *Archaeopteryx* hand[1]. Yet their illustrations of the hands in the Berlin specimen (Figs 3,4 in ref.3) show the feature in question unequivocally labelled as "break". Their description (ref.3, p.155) is equally assertive: the feature "is apparently a break, not a joint... contrary to the opinions of Heilmann[6], Wellnhofer[7] and Ostrom[8]". Evidently Howgate did not misrepresent the views of Hecht and Tarsitano.

Hecht and Tarsitano accuse Howgate of attempting to make their explanations appear "ludicrous". But if the problematical feature in the outermost finger is a joint (and not a break) then their explanation *is* ludicrous: it would maintain[1] that a finger-joint "was caused by forces during stalling, impact upon the water, or as a result of preservation".

Finally Hecht and Tarsitano are not accurate in summarizing the issue. The important point is not whether the three digits in question are numbers 1-2-3 or numbers 2-3-4; it is whether or not the three fingers are homologous in theropods, birds and *Archaeopteryx*. Some biologists maintain that they are, whether they be 1-2-3 (ref.9) or 2-3-4 (ref.5). Hecht and Tarsitano disagree, contending that the three fingers of birds (including *Archaeopteryx*) are not homologous with the three fingers of theropods. But their argument is not convincing: it entails a complex explanation (convergence) where a simple one might suffice; it conflicts with the cladistic methodology that Hecht and Tarsitano claim to espouse (ref.5, p.621); and it implies that theropods differed from all other tetrapods (except syndactylous marsupials) in their pattern of digital reduction (ref.3, p.161). Despite these difficulties Hecht and Tarsitano have sought to defend their opinions. It is unfortunate that they should do so by ignoring any arguments to the contrary and by claiming that others have misrepresented and distorted their views.

Tectonics and structural zonation of southern Tibet, China

J. P. Burg* & **G. M. Chen**†

The Yarlung Zangbo suture zone is composed of several thrust sheets with distinct stratigraphies, states of deformation and metamorphic grades. Successive deformations have been produced by persistent north–south shortening since obduction of the ophiolites by late Cretaceous–Palaeocene times. A possible decoupling of the crust may be associated with the intracontinental thrust system which has formed in the subducted Indian plate. This article emphasizes the role of shear deformations in the building of a collision belt.

THE Yarlung Zangbo suture zone (YZSZ) in southern Tibet (China) marks the site of collision of the Eurasian and Indian continental plates after closure of the Tethys Ocean[1–4]. Collision is thought to have occurred in the Eocene[4–6], when the northward motion of India slowed rapidly from 10 cm yr^{-1} to 5 cm yr^{-1} (ref. 7). Since then, India has moved ~2,000 km further northwards relative to Asia[8,9] with underthrusting of continental India beneath Asia[10,11] and lateral expulsion of Asian crustal wedges bounded by strike-slip faults[7,12,13]. The aims of this article are: first, to examine and interpret the structural pattern of the YZSZ; and second, to assess the relative roles of obduction and intracontinental deformation in the tectonic evolution of the area. In the region visited (Figs 1, 2), the three following tectonolithostratigraphical units can be recognized in a north–south direction: the Lhasa Block; the Yarlung Zangbo suture; and the north Indian margin.

Lhasa Block

Before the collision, the northern margin of the Tethyan ocean consisted of Precambrian basement overlain by Carboniferous to Upper Cretaceous shallow water sediments which contain the Cretaceous Cathaysian flora[14,15]. The southern margin of the marine Lower Mesozoic basin may have deposited on an oceanic crust[16]. Shallow water and subaerial sediments associated with a Cretaceous–Palaeocene[17] ignimbritic series overlie eroded folds of the Upper Cretaceous and older rocks. The southern portion of the Lhasa Block is dominated by the Transhimalayan Plutonic Belt[3] in which radiometric ages range between 120 and 40 Myr (ref. 18). We have summarized the geological history of the Lhasa Block as follows[16]: Lower Cretaceous metamorphism probably accompanied the development of small scale isoclinal F_1 folds, an axial planar S_1 foliation and north–south stretching lineation. The intensity of the F_1 fabric and metamorphism increase towards the Yarlung Zangbo suture. The deformation and metamophism are related to northward subduction while calc-alkaline magmatism of the Transhimalayan Belt takes place possibly along a continent–ocean margin, leaving remnants of continental Precambrian crust to the north and of (Triassic?) oceanic crust to the south. A period of continuing crustal shortening associated with further intrusions gave rise to F_2 folding with fanlike S_2 cleavage and subvertical axial surfaces. The F_2 structures steepen the shallow

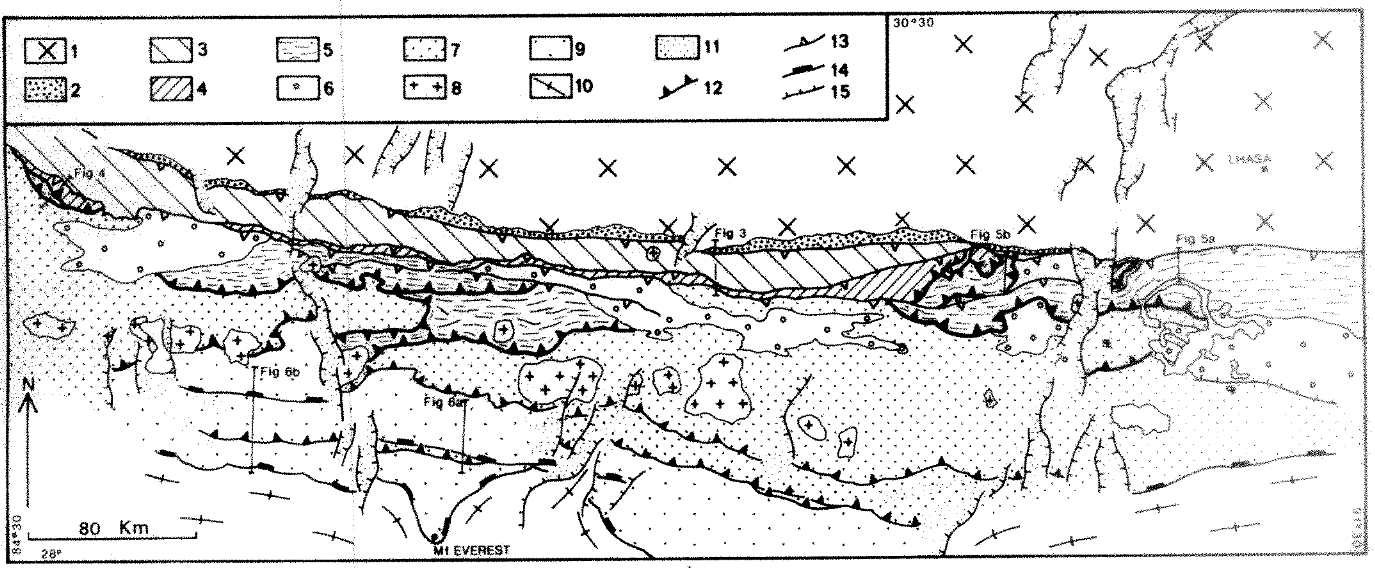

Fig. 1 Locations of the cross-sections on a simplified geological map of the YZSZ in southern Tibet. 1, Upper Palaeozoic to Cenozoic sedimentary rocks, Precambrian basement, calc-alkaline plutons and volcanites of the Lhasa Block; 2, conglomerates (Eocene?) lying unconformably on the Lhasa Block; 3, Cretaceous turbidites (Xigaze series) of the forearc basin; 4, Tsangpo ophiolites; 5, infra-ophiolitic thrust sheets of radiolarites and (Upper Triassic–Liassic?) turbiditic flysch; 6, unconformable (Maestrichtian?) wildflysch with exotic blocks and overlying black shales and quartzite; 7, north Tethyan sediments (with polyphase deformation and metamorphism); 8, North Himalayan two-mica granites and crystalline rocks; 9, south Tethyan sediments (unmetamorphosed and with one major phase of folding); 10, Main Central Crystalline Sheet; 11, Quaternary; 12, southward thrusts; 13, backthrust (post-Miocene); 14, post-Miocene northward normal fault; 15, Quaternary normal faults.

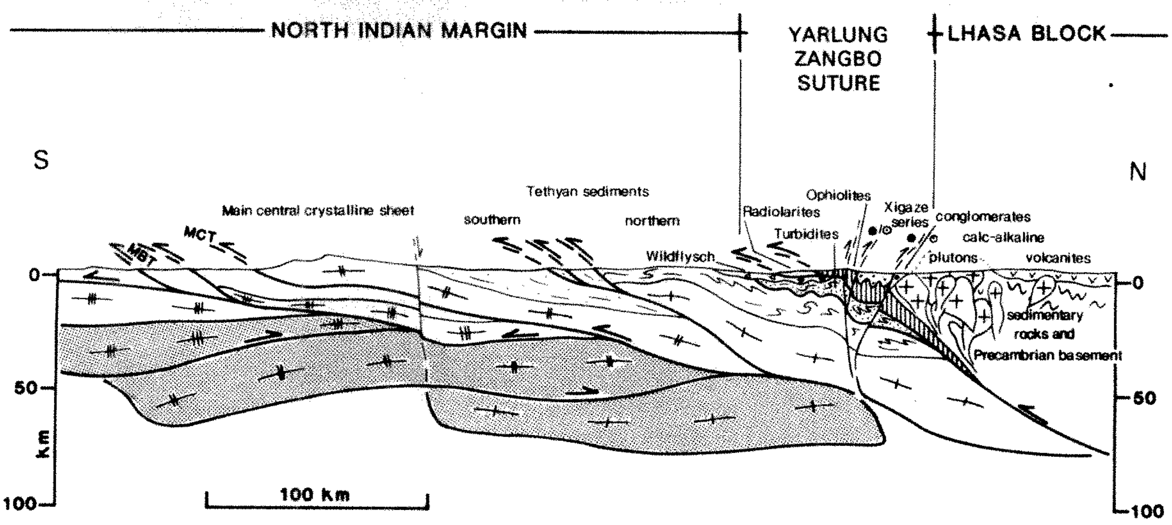

Fig. 2 Synthetic and interpretative cross-section of the YZSZ and relationship to north Indian margin and Lhasa Block. Moho and deep structures adapted from refs 44, 47. Shaded areas are lower crust layers corresponding to the upper crust layers with same gneiss symbols (after refs 44, 47). MCT, Main Central Thrust; MBT, Main Boundary Thrust[1].

dipping S_1 and could be produced from an Andean type orogen. Emersion and erosion by uppermost Cretaceous times truncated all the structures. The uncomfortable Palaeocene has undergone minor shortening with undulations of low amplitude and several kilometres wavelength and low-angle reverse faults with less than a few kilometres displacement. This indicates that significant crustal shortening was completed here by the Palaeocene; late granitic plutons intrude the Palaeocene series.

South of the Transhimalayan Plutonic Belt conglomerates are intercalated with red shales, sandstones and local basaltic and ignimbritic flows. The sequence is comparable with the Indus Molasse of Eocene age in Ladakh[19] and in the Kailas[20] and displays one phase of east–west folding with a northward vergence and a weak steep dipping cleavage. The folds could be related to the near vertical or south dipping fault traced along the southern margin of the Lhasa Block (Fig. 1). Slickenside striation on the fault plane and related fractures indicate dextral wrench faulting before northwards thrusting.

Yarlung Zangbo suture

The YZSZ is traditionally traced along the ophiolite sheets[2,21], which are the eastern continuation of those recognized in southwest Tibet[22] and in Ladakh (western Himalayas[19,23]). We attribute three rock subunits to the suture (Figs 1, 2). They are from the north to the south Cretaceous turbidites (the so-called Xigaze series)[24], ophiolites and associated radiolarites, and allochthonous turbidites. The suture has been reactivated by northward backthrusting and dextral strike-slip movement. The reason why all these rock subunits are not present on every transect may be a primary discordance between their earlier limits and the late faults.

The northern section of the Xigaze series is composed of a turbidite sequence with Aptian–Albian limestones[25] and conglomerates containing pebbles of plutonic and volcanic calc-alkaline rocks[26,27] which show that this sequence was deposited near the Transhimalayan Belt whose erosion was occurring by the late Cretaceous. The southern section is composed of pelagic sediments with Albian–Cenomanian radiolarites forming the sedimentary cover of pillow lavas[28]. The Xigaze series appear within a large east–west trending synclinorium shortened ~40% after the early Cenozoic (Fig. 3) with dominantly southward verging folds, a steep dipping cleavage and no metamorphism. The Xigaze subunit has been interpreted as a forearc basin lying on the plutonic belt to the north and on the ophiolites to the south[26,27]. As we have emphasized the existence of an important fault between the turbidites and the Lhasa Block, the floor of the sediments which overlie pillow-lavas to the south could only be an oceanic crust. To the west we have recognized an Upper Barremian–Lower Cenomanian limestone formation (bearing orbitolinids) interlayered with basaltic and possibly andesitic flows. The formation is squeezed between backthrusts along the southern boundary of the Xigase subunit and could imply that the calc-alkaline lavas have flowed southwards towards the oceanic floor of the Xigaze series. Note that in Ladakh, similar associations of the same age have been found in the Dras formation[29] where calc-alkaline lavas overlie oceanic basalts[30].

Nicolas *et al.*[31] have noted the abundant faults and the normal polarity of the ophiolites which now tectonically overlie the sedimentary series described below with the major faults being north dipping thrusts subparallel to the layering. A tectonic mélange with a matrix of serpentinites locally appears within the thrusts. The infra-ophiolitic sole is a package of Cretaceous (and Jurassic?[26]) slightly metamorphosed radiolarite slices with tuffs and basaltic flows (Fig. 4). The sequence is dominated by numerous contacts subparallel to an S_1 cleavage which is axial planar to small scale isoclinal folds (rarely sheath folds). The N150–220 fold axes are parallel to a stretching lineation L_1 marked by quartz fibres within S_1 and slickensides within the thrust planes. The F_1 folds are refolded by N030–150 south facing chevron folds F_2. Both folding events are attributed to the emplacement of the ophiolitic nappes, the stretching lineation being parallel to the tectonic transport from north to south as indicated by the sense of displacement on thrusts and the direction of vergence.

An uncomfortable polygenic and coarse subaerial conglomerate appears only along the ophiolite–radiolarite outcrops and is considered to be Oligo-Miocene[32]. This conglomerate is deformed in the south-dipping backthrusts (unit 4, Fig. 3 and unit 6, Fig. 4) indicating that this important faulting due to north–south compression is a recent event.

The ophiolites and the radiolarites are thrust onto an allochthonous turbidite sequence (Fig. 2) with late Triassic to Liassic marine fossils[33,34]. This turbidite subunit is comparable to the Indus Flysch[19]. To the west a lower nappe of similar turbidites containing blocks of cherts and crystalline limestones could be equivalent to the Namika La Flysch[35]. Large-scale recumbent F_1 folds (Fig. 5) have inverted the stratigraphical series. Southwest verging mesoscopic F_1 folds trend N030–180 and contain an S_1 slaty cleavage formed in low-grade conditions of metamorphism. Quartz fibres and long axes of pressure fringes are parallel to the N340–030 stretching lineation Le which can be equated with a transport direction (Hansen's method[36]). Basal thrusts of this subunit and of the ophiolites and their sole cut

S_1 cleavage of the Xigaze series. The arrows indicate the younging direction.

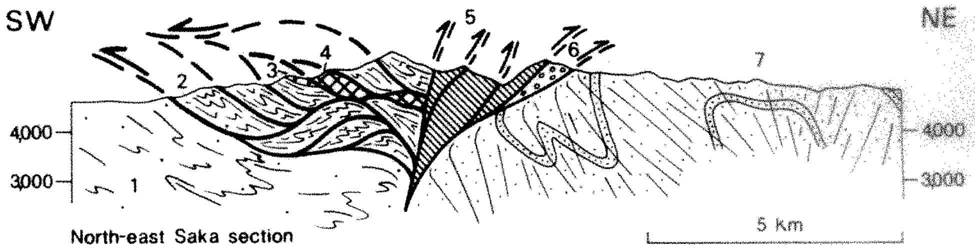

Fig. 4 North Saka cross-section. 1, North Tethyan sediments with isoclinal folding and subhorizontal S_1 cleavage. 2, Radiolarite slices containing recrystallized limestones and imbricate (3) with, basalts and tuffs (4), ophiolites (5) backthrusted onto, Oligo-Miocene (Liuqu) conglomerates (6) and Xigaze series (7).

the F_1 structures and are marked by some crush zones, metres thick, formed in non or very low grade conditions of metamorphism. Both the thrust contacts and the F_1 folds are folded about F_2 structures (Fig. 5) in various ways, as the upright chevron folds (interlimb angles 110–50°) may coexist with subisoclinal folds (interlimb angles ~20°) with rounded hinges and overturned to the south. The F_2 axes are parallel to a N060–120 crenulation lineation. F_2 folding increases in intensity northwards and is contemporaneous with intrusion of two mica granites recognized in the North Himalayan Belt (Fig. 1). Local N040–130 kinks with different axial plane attitudes are attributed to an F_3 event and may be contemporaneous with post-F_2 movement along basal thrusts.

North Indian Margin

The sedimentary sequence which formed in a continental shelf environment on the Indian Shield (carbonates and shales) passed northwards into a deeper water facies (pelites and flyschs). A major thrust separates the northern and southern Tethyan sequences thus defining two subunits (Figs 1 and 2).

The north Tethyan sediments show downward increasing metamorphism from regional low grade to localized staurolite kyanite schist. In the structural section, the lowest rocks are Lower Ordovician orthogneiss[37,38] underlying metamorphosed rocks and recrystallized Permian limestones[33]. Overlying the Permian, the Mesozoic includes a thick and monotonous calcareous flysch of up to Turonian age[39] involved in polyphase deformation. The first major event generated large-scale recumbent folds overturned to the south-west and a well developed slaty cleavage S_1 with a N350–040 stretching lineation. The bulk strain increases northwards towards the YZSZ and upwards under the ophiolitic and associated nappes. An unconformable wildflysch with exotic blocks is lying on these deformations (Figs 1 and 2). The blocks are composed of Permian to Maestrichtian rocks locally more deformed than the matrix and derived from the north. The youngest fossils found in the blocks and in the locally layered matrix are Maestrichtian to Palaeocene which is taken as the age of this synorogenic formation overlain by undated black shales and quartzites. If the age of the wildflysch is correct, the major thrusting events are thus Upper Cretaceous–Palaeocene in age. The wildflysch and the black shales have been folded about upright east–west trending folds (Fig. 5) with a non metamorphic fanning cleavage parallel to the bulk axial plane; this cleavage is a crenulation cleavage in the older rocks. The folding is equated with the F_2 event of the turbidite nappes. The structurally lower metamorphic rocks show a comparable polyphase deformation with an unexpected downward increase in intensity of the fabric contemporaneous with the intermediate pressure metamorphism[40]. The problem which arises is that radiometric ages of micas are 13 Myr (Ar/Ar method, H. Maluski, personal communication) and hence inconsistent with the Maestrichtian–Palaeocene age of the F_1 structures as suggested above. It is proposed that both the deformation and the metamorphism of the lower rocks are associated with a ductile thrust zone whose deformation front does not reach the upper part of the pile but instead produces the thrust and locally a trailing imbricate fan to the south between the northern and southern Tethyan sediments (Fig. 2). The juxtaposition of two areas having comparable fabrics, though they are different in age, is one of the striking features of the northern subunit. This is a consequence of the heterogeneity of the shear deformation during thrusting, which affects areas close to the thrust plane and preserves the sequence away from the thrust. The F_2 upright folding throughout the north Tethyan sediments is contemporaneous with late Miocene emplacement of two-mica granites of the North Himalayan Belt.

The southern Tethyan sediments range in age from Cambrian to Eocene[33] without any significant unconformity and are of the 10-km thick platform type series identical to that known further west in Ladakh[23]. In contrast to the north Tethyan sediments they are non-metamorphosed and have suffered one main phase of east–west trending box and chevron folds (Fig. 6) that can be followed for tens of kilometres along their axial traces. Intensity of shortening decreases southward and a faulted contact separates the southern Tethyan sediments from metamorphosed schists intruded by Miocene leucogranites of the Main Central Crystalline Sheet (Fig. 2). The faulted contact has been interpreted as a thrust[27] which is not consistent with the northward shearing in the leucogranites[41] and the normal faulting suggested by the superposition of unmetamorphosed sediments onto staurolite garnet schists. To the east, the steeply dipping normal fault separates Jurassic schists from gneisses indicating at least 8,000 m of vertical movement.

The basal thrust (MCT) of the Main Central Crystalline Sheet is not exposed in Tibet[27]. The youngest formations overlain by the MCT (Fig. 2) are Miocene thus dating the Main Central Crystalline Sheet emplacement. An underlying thrust sheet is represented by the Main Boundary Thrust (MBT) which continues to produce modern seismicity in a north–south compressive regime[42,43].

Conjectural deep structure

The interpretations and implications of the geophysical data for the deep structure in Tibet are twofold:

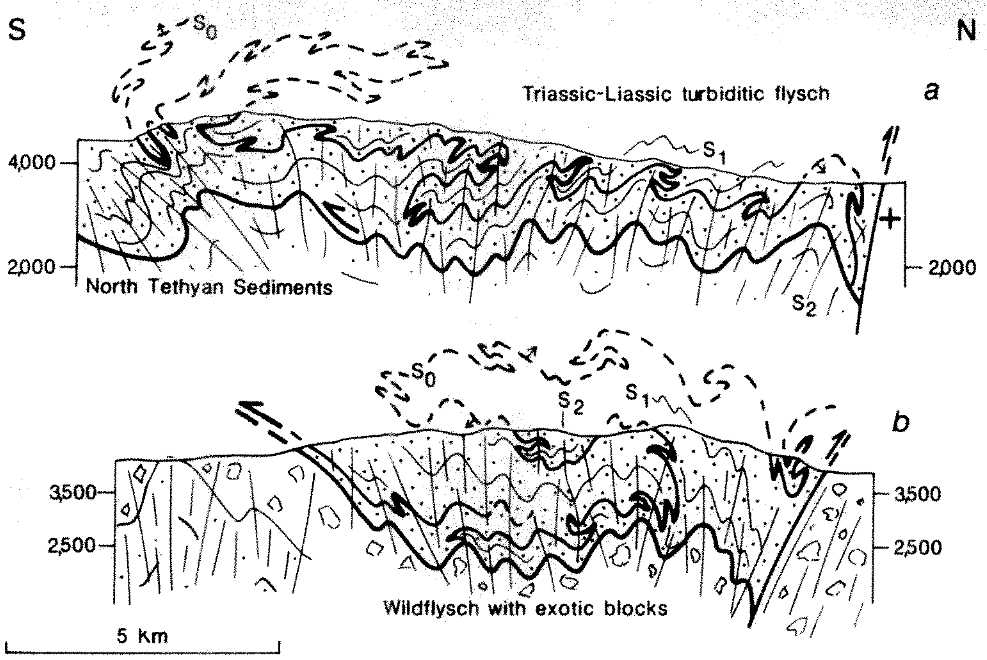

Fig. 5 Two detailed cross-sections in the Triassic–Liassic turbidite flysch. They show polyphase deformation with S_1 cleavage and S_2 crenulation cleavage. Bedding S_0–S_1 relationships and younging directions (arrow) give evidence for several kilometres inverted series. Thickening of F_1 hinges is voluntary exaggerated. Lower Cretaceous calcschists underlie the wildflysch.

(1) The major thrust sheets (MCT, MBT and the northern Tethyan sediments) correspond to the prism-shaped seismic structures reported by Hirn *et al.*[44]. Crustal shortening and thickening of the North Indian Margin is produced by decoupling and thrusting separating lower and upper crustal layers. The superposition of the neighbouring segments of the upper crust occurs along imbricate thrusts with polarity opposite to, though contemporaneous with, thrusts in the lower crust which may involve upper mantle rocks (ref. 44, interpreted in Fig. 2). The upper crust can slide and/or fold independently of the lower crust. A similar situation may have been identified in the Alps[45] and requires splitting of the crust with major thrust zones merging towards the inner part of the belt into a unique shear zone within the crust. The driving force necessary to initiate and develop such a thrust configuration implies a crustal process. Consequently, the origin of the merging shear zones may possibly be connected with the subduction zone itself. The evolution of the thrust system as drawn in Fig. 2 leads to steepening of the inner thrust planes (and the suture) by growth of the underlying outer crystalline sheet. The vertical inner thrust zones and the suture then become rejuvenated as wrench faults, as observed in southern Tibet and as proposed in the Variscan Belt[46].

(2) The geophysical data suggest an almost 20-km step precisely below the surface traces of the boundaries of the Main Central Crystalline Sheet and of the Lhasa Block (Fig. 2), which are both recent and prominent faults. Hirn *et al.*[47] point out that the fault limiting the Lhasa Block is a vertical contact which is consistent with strike-slip movements. Moreover, a variation in the level of the Moho can be identified further north[47] indicating that if the deep crust topography is due to post-Miocene disruptions as suggested by geological data, crustal thickening since the Miocene did not occur through mere underplating of several hundred kilometres of continuous Indian Crust beneath Tibet (600–1000 km with a mean motion of 3–5 cm yr^{-1} since 20 Myr).

Conclusions

In the YZSZ, several thrust sheets have distinct stratigraphies, states of deformation and metamorphic grade. The movement pattern is that the earliest strains are consistent with some oceanic crust being subducted to the north. This was accompanied by Andean type deformation and magmatism south of the Lhasa Block, and possibly by a period of rapid erosion as northly derived rocks were deposited in the forearc Xigase basin. This suggests that the crust of the Lhasa Block might

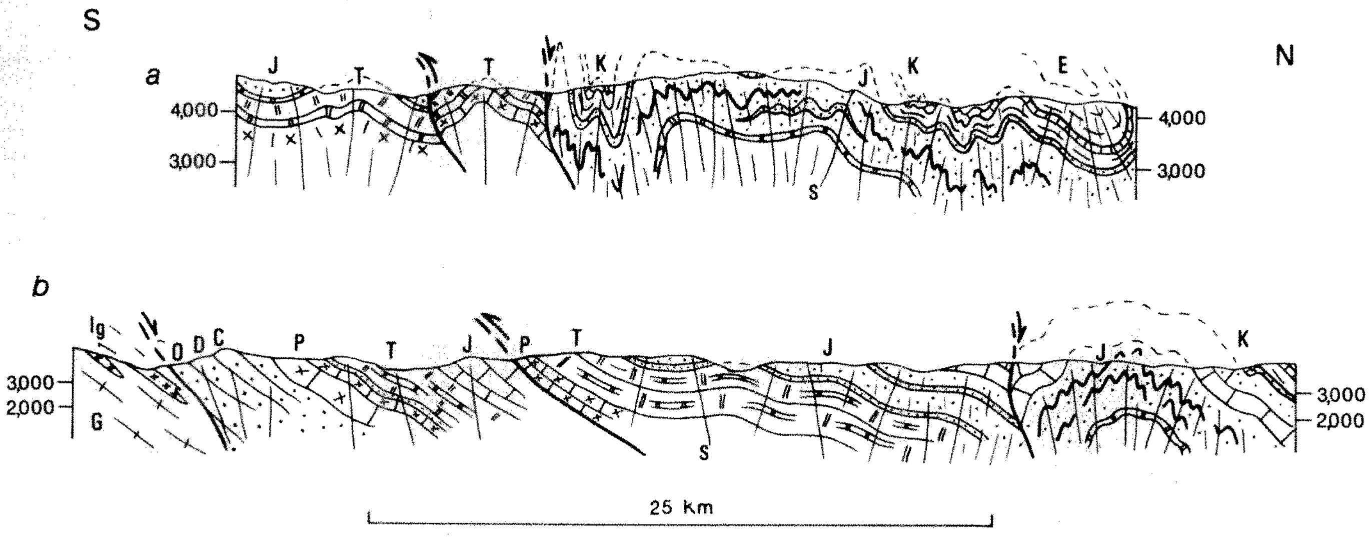

Fig. 6 Two examples of section across the south Tethyan sediments: G, gneisses of the Main Central Crystalline Sheet intruded by lg, Miocene leucogranites; O, Ordovician; D, Devonian; C, Carboniferous; P, Permian reef limestones; T, Triassic; J, Jurassic limestones, shales and sandstones; K, Cretaceous calcschists and limestones; E, Eocene nummulite-bearing limestones; S, weak spaced cleavage.

have been thickened before the India–Asia Collision. The Lhasa Block and the ophiolites which carry the Xigaze series represent the overriding plate in which magmatism terminated in the Eocene. At this time, the deformation of the overriding plate was substantially less than that of the subducted plate except along its southern edge. The southward obduction of the suture rocks took place while the wildflysch was deposited (Maestrichtian–Palaeocene?). The bulk strain of this age increases upwards in the suture region with the development of a subhorizontal cleavage and roughly north–south stretching lineation. A deformation pause may be represented by the unconformity between north Tethyan sediments and the wildflysch, although it is not necessarily an orogenic pause as thrusting and associated shearing may develop in lower parts of the crust. Post-collision deformation involved intracontinental thrust zones in the subducted plate, associated with intermediate pressure metamorphism, two-mica granite intrusions and widespread upright folding. In the North Indian Margin, intracontinental thrust zones with upward decreasing deformation create deformation belts different in ages though having the same fabric feature because they result from persistent north–south compression. Later events include the rejuvenation of the suture into transcurrent movements and post-Miocene backthrusting.

This article is a digest of J.P.B.'s thesis presented in Montpellier in May 1983. The work was carried out within the Cooperative Research Project of the Chinese Geological Academy, Chinese Academy of Sciences, French CNRS and Institut National d'Astronomie et de Geophysique. J.P.B. thanks all his colleagues who participated in the fieldwork in southern Tibet, during which time some of the ideas presented here evolved. We thank C. J. L. Wilson for help with the English and I. Munro who typed the manuscript.

Information for the dorsal–ventral pattern of the *Drosophila* embryo is stored as maternal mRNA

Kathryn V. Anderson & Christiane Nüsslein-Volhard

Friedrich-Miescher-Laboratorium der Max-Planck-Gesellschaft, Spemannstrasse 37–39, 7400 Tübingen, FRG

Maternal-effect mutations in 10 loci in Drosophila *produce totally 'dorsalized' embryos. Injection of RNA isolated from wild-type embryos into mutants at six loci partially restores dorsal–ventral polarity. For the mutant* snake, *injection of poly(A)$^+$ RNA restores a complete dorsal–ventral pattern.*

DESPITE decades of research, the molecular mechanism underlying pattern formation have eluded developmental biologists. Although several molecules have been identified which clearly elicit specific morphogenetic responses, including retinoic acid, *Dictyostelium* DIF and hydra head activator[1–3], it is not clear whether these are normal *in vivo* morphogens. More significantly, even the identification and characterization of an *in vivo* morphogen cannot, in isolation, explain the position-dependent activity of that molecule within an embryonic field. The genetic dissection of pattern-forming processes provides a means of defining specific morphogenetically active substances, and, at the same time, permits studies of interactions between components of the system which are required for position-dependent development.

The establishment of the dorsal–ventral pattern in the *Drosophila* embryo is a genetically defined system both for the identification of the *in vivo* morphogenetically active molecules and for the study of interactions between regulatory components[4]. The dorsal–ventral embryonic pattern is directed by a defined group of maternal-effect genes dispersed throughout the genome, which have been identified in recent saturation screens for female sterile mutations (refs 5–7; T. Schüpbach, personal communication; C.N.-V., K.V.A., G. Jürgens and R. Lehmann, unpublished observations). Ten loci have been found which are required for the production of lateral and ventral pattern elements. For each locus, lack of gene function in the mother, results in an embryonic phenotype identical to that described for the maternal-effect mutation *dorsal*, where all

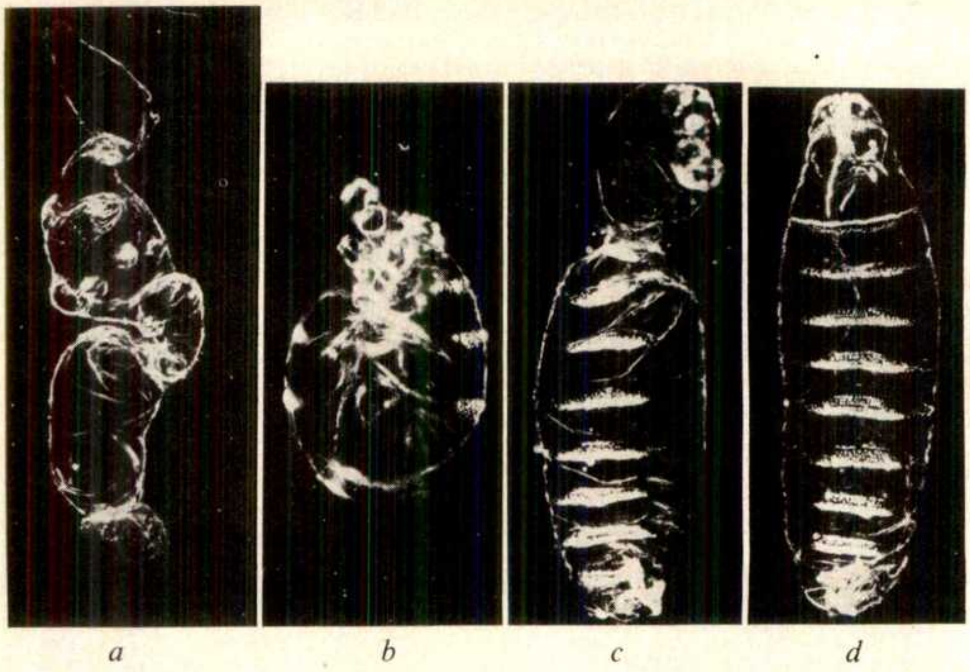

Fig. 1 Rescue by injection of wild-type cytoplasm into *easter*, *tube* and *snake Drosophila* mutants. Cuticle preparations of uninjected *easter*, *tube* and *snake* embryos all show the same tube-like form of dorsal cuticle (*a*, uninjected *snake* embryo). The maximal extent of the phenotypic rescue for each locus, shown here, is characteristic for each locus. Of these three, *easter* (*b*) responds the most weakly to injection, generally developing only filzkörper in addition to dorsal cuticle and occasionally narrowed rows of ventral denticles, as shown here; *tube* (*c*) responds more strongly, typically developing ventral denticles in addition to filzkörper; *snake* embryos (*d*) show a total restoration of dorsal–ventral pattern elements after injection. The embryo in *d* had hatched before being mounted.
Methods: For injection, both mutant embryos and wild-type Oregon R donor embryos were collected for 1 h at 18 °C, dechorionated in 50% bleach and mounted on double-sided sticky tape. Embryos were dried for 20–25 min at 18 °C in a silica gel-containing chamber and were then covered with Voltalef 10S oil. Injections were done at 18 °C with a 5–7 μm diameter glass micropipette. The total content of a single wild-type donor was used to inject into ~30 mutant hosts, thus the volume of cytoplasm injected corresponds to ~3% of the total egg volume. The cytoplasm was injected into the central yolk at a posterior position. Embryos which had formed pole cells and older embryos were not used as donors or hosts. Embryos were allowed to develop for 3 days at 18 °C, and cuticle preparations were made[9]. Mutant *easter* embryos were obtained from ea^{IIR65} homozygous females, *tube* embryos from tub^{238}/tub^{118} females, and *snake* embryos from snk^{073}/snk^{229} females.

embryonic cells develop like the dorsal-most cells of the wild-type embryo[4,8]. The common phenotype produced in the absence of any one of these gene functions indicates that each is an essential component of one pattern-forming process.

The recent demonstration that the phenotype of embryos produced by homozygous *dorsal* females can be partially rescued by injection of wild-type cytoplasm[9] established a specific assay for the molecules required for expression of the embryonic dorsal–ventral pattern. Here we use this phenotypic rescue assay to demonstrate that the information from several of the 'dorsalizing' maternal-effect genes is found in the wild-type egg in the form of poly(A)$^+$ RNA.

Phenotypic rescue of dorsalizing loci

During a saturation screen for female sterile mutations on the third chromosome of *Drosophila*, we identified mutants falling into eight complementation groups which produced dorsalization of the embryo (Table 1). For all loci, the embryonic mutant phenotypes are indistinguishable from those of the previously described loci *dorsal*[8,10] and *gastrulation defective*[11]. Embryos produced by females homozygous for amorphic alleles of any of these genes show no polarity in the dorsal–ventral axis and all cells differentiate like the dorsal-most cells of the normal embryo. The dorsalized phenotype can be seen in cuticle preparations of differentiated, unhatched larvae, where the cuticle is a long tube covered with the fine hairs normally found only dorsally. Early in development, in contrast to the highly asymmetric pattern of normal gastrulation, the mutant pattern of folding at gastrulation is totally symmetrical in the dorsal–ventral axis. As previously shown for *dorsal*[12], this embryonic phenotype apparently results from a shift in the position-dependent fate of cells along the dorsal–ventral axis of the blastoderm embryo.

Pursuing the observation that injection of wild-type cytoplasm partially rescues the *dorsal* phenotype[9], we found that injection of wild-type cytoplasm into young mutant embryos modifies the mutant phenotype for six of the eight newly identified third-chromosomal loci (Fig. 1 and Table 1). Although the phenotypic rescue in all cases results in a partial restoration of the dorsal–ventral pattern, mutants at each locus show a characteristic degree of response to injected cytoplasm. Differentiation of filzkörper was used as the minimum criterion of rescue. This structure, normally derived from a dorso-lateral position in the blastoderm fate map, is easily identifiable in cuticle preparations. Ventral denticles, which are normally derived from a ventro-lateral position, were taken as evidence of stronger rescue. The

Table 1 Maternal-effect dorsalizing loci

Locus	Map position	Cytological localization	No. of recessive alleles	Phenotypic rescue by cytoplasm	by RNA
gastrulation defective	1–37	11A1–7	8	–	ND
dorsal	2–52.9	36C	11	+	–
nudel	3–17	–	8	ND	ND
tube	3–47	–	2	+	+
pipe	3–47	–	2	–	ND
snake	3–52	87D10–12	4	+	+
easter	3–57	88EF	13	+	+
Toll	3–91	97D	28	+	+
spätzle	3–92	97E	2	+	+
pelle	3–92	97F	6	+	+

Gastrulation defective and *dorsal* have been described previously[8,11]. Most alleles of the third chromosomal loci were recovered during a systematic screen for female steriles, described elsewhere (refs 5, 6; T. Schüpbach, personal communication; C.N.V., K.V.A., G. Jürgens and R. Lehmann, unpublished observations) Rice[7] isolated two alleles of *nudel* (his alleles *mel*(3)2 and 5), one allele of *snake* (*mel*(3)4), two alleles of *Toll* (*mel*(3)9 and 10), one allele of *spätzle* (*mel*(3)7), and one allele of pelle (*mel*(3)8). Twenty-four of the *Toll* alleles were recovered as revertants of the dominant female sterile *Toll* mutations (refs 4, 10 and K.V.A., unpublished). Ten alleles of *easter* were isolated by F. Müller-Holtkamp. The cytological location of *snake* is defined by its inclusion in Df(3R)ry^{36} and exclusion from DF(3R)kar^{1G27} (ref. 12); *easter* maps by recombination between *jvl* and *sbd*[23], and is included neither in Df(3R) sbd^{105} (ref. 25) nor in the deficiency from T(3;1)kar^{51} (ref. 26). *Toll*, *spätzle* and *pelle* are defined primarily by aberrations isolated as revertants of the dominant *Toll* alleles (K.V.A., unpublished). ND, not determined.

Table 2 Phenotypic rescue of *snake* by injection of cytoplasm and RNA

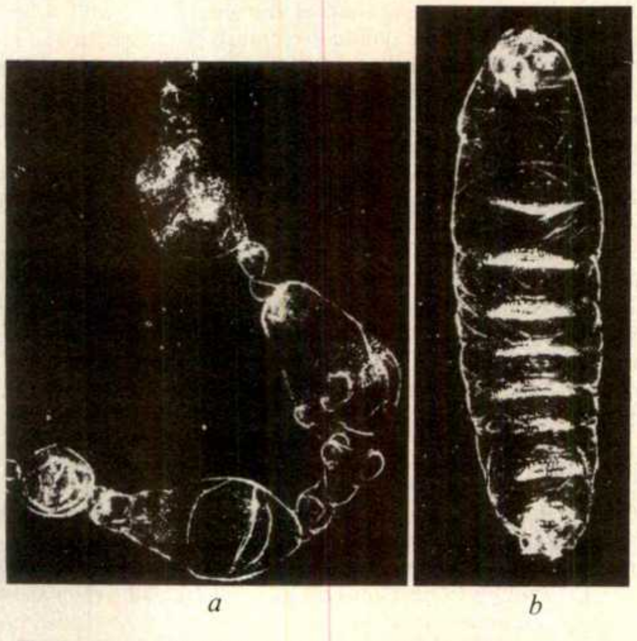
Maternal genotype of donor embryos	Material injected	No. of recipient embryos Total	Differentiated	Rescued	% Rescued (of differentiated embryos)
+/+	Cytoplasm	439	122	119	98
snk/snk	Cytoplasm	102	36	0	0
+/+	Total RNA, 18 mg ml^{-1}	116	60	46	77
+/+	Total RNA, treated with RNase A*	97	33	0	0
+/+	Total RNA, alkaline hydrolysate*	113	34	0	0
+/+	Poly(A)$^-$RNA, 16 mg ml^{-1}	166	61	0	0
+/+	Poly(A)$^+$RNA, 6 mg ml^{-1}	208	61	54	89
+/+	Poly(A)$^+$RNA, treated with RNase A*	174	57	0	0
snk/snk	Polt(A)$^+$RNA, 9 mg ml^{-1}	141	54	0	0

Injection and RNA isolation methods are described in the legends to figs 1 and 2. Embryos were considered differentiated when the cuticle phenotype could be unambiguously scored for filzkörper and ventral denticles. Rescue was defined as the development of filzkörper.

* A single RNA preparation was split and used for the samples with and without RNase treatment. RNA was incubated with 2 μg ml^{-1} RNase A for 20 min at 25 °C. RNase was removed by phenol-chloroform extraction. For alkaline hydrolysis, an aliquot of the same RNA sample was incubated for 10 min in 0.2 M NaOH at 25 °C, then neutralized and reprecipiatated with ethanol before injection.

response of *spätzle* is similar to that seen with *dorsal*[9], with many injected embryos developing filzkörper. Most injected *easter* embryos develop filzkörper, and, in addition, ventral denticles are also seen occasionally. Injected *tube*, *pelle* and *Toll*^{rec} embryos respond more strongly: many develop well-organized rows of ventral denticles in addition to filzkörper. The most dramatic effect is seen with *snake*: this is the only case where injection of wild-type cytoplasm completely restores the normal dorsal–ventral pattern.

The characteristic response of mutants in each locus to injected cytoplasm indicates that different components of wild-type cytoplasm produce the rescue response in the different mutants. This is shown directly by the fact that in all cases examined so far, cytoplasm from dorsalized embryos resulting from mutations at one locus can rescue the phenotype of dorsalized embryos from mutations at other loci. For example, *snake* embryos, although not rescued by cytoplasm from other mutant *snake* embryos, are rescued by cytoplasm from mutant embryos of all nine other dorsalizing loci.



a *b*

Fig. 2 Rescue of *snake* by injection of poly(A)$^+$ RNA. *a*, Cuticle of uninjected *snake* embryo; only the dorsal cuticle is differentiated. *b*, Cuticle of *snake* embryo injected with 10 mg ml^{-1} poly(A)$^+$ RNA isolated from wild-type embryos, showing a full dorsal–ventral pattern including ventral denticle belts of normal width. RNA was isolated from 0–2-h Oregon R embryos by phenol–chloroform extraction and proteinase K treatment[15]. Poly(A)$^+$ RNA was isolated by one cycle of binding to oligo(dT)-cellulose as described elsewhere[15], except that SDS was omitted from the buffers. The concentration of RNA was measured by absorbance at 260 nm. The injection procedure was similar to that described for cytoplasm. RNA was injected in 25 mM KCl, 2.5 mM PIPES, 0.5 mM EDTA, 25% glycerol.

Total rescue of *snake*

A typical dorsalizing maternal-effect gene, both genetically and phenotypically, is *snake*. Four alleles of *snake* have been isolated, three in our laboratory and one by Rice (*mel*(3)4) (ref. 7). By deficiency complementation, *snake* maps in the polytene bands 87D10–12. Only two complementation groups in this cytological interval, *rosy* and *l(3)S12* (ref. 13), have been identified in saturation screens for lethal and visible mutations. Mutants in *snake* are viable, have normal eye colour and are female fertile in *trans* to *rosy* and all alleles of *l(3)S12*, thus it is probable that there are no visible or lethal alleles of *snake*. *Snake* is a pure maternal-effect gene: all allele combinations and all alleles in *trans* to deficiency are fully viable, male fertile, and mutant females produce totally dorsalized embryos, even when fertilized by sperm carrying two copies of the *snake*$^+$ gene.

Snake embryos show a dramatic response to injection of wild-type cytoplasm. Although the total volume of cytoplasm injected is only 3% of the total egg volume, a completely normal dorsal–ventral cuticular pattern is restored in nearly all differentiating embryos (Fig. 1). Over 20% of the rescued embryos hatch into larvae, which can develop further into normal adults. This complete restoration of the dorsal–ventral pattern can be observed within 2 h after injection, when nearly all developing embryos gastrulate normally, including the formation of a ventral furrow. This dramatic response contrasts with the other loci studied, where hatching larvae have not been obtained. The strong response of *snake* to injected cytoplasm makes it ideal for the investigation of the molecular nature of the rescuing activity.

Poly(A)$^+$ RNA rescues *snake*

Mutant *snake* embryos can be rescued by wild-type cytoplasm up to the stage of pole cell formation, indicating that the function of the *snake* gene is required after that time. The information encoded by the *snake* gene is thus synthesized during oogenesis, stored in the egg, and becomes necessary for embryonic pattern formation only some time after fertilization. This observation suggested that the *snake*-rescuing activity might be stored in the egg in the form of maternal mRNA.

In order to test whether the *snake*-rescuing activity is RNA, cytoplasmic RNA purified from cleavage stage wild-type embryos was injected into *snake* embryos. The injection of RNA

Table 3 Characteristics of rescue by cytoplasm and RNA for *snake*, *tube* and *easter*

Maternal genotype of recipient embryos	Stage of wild-type donor embryos	Material injected	% Of differentiated embryos			
			with Filzkörper	with ventral denticles	hatched	(*n*)
snake	Cleavage	Cytoplasm	98	98	20	(122)
		Total RNA	77	15	0	(60)
		Poly $(A)^+$ RNA	85	57	0	(204)
	Extended germ band	Cytoplasm	34	0	0	(139)
		Poly$(A)^+$ RNA	45	0	0	(53)
tube	Cleavage	Cytoplasm	89	48	0	(65)
		Total RNA	59	0	0	(69)
		Poly$(A)^+$ RNA	77	17	0	(100)
	Extended germ band	Cytoplasm	72	49	0	(67)
		Poly$(A)^+$ RNA	18	0	0	(61)
easter	Cleavage	Cytoplasm	83	6	0	(219)
		Total RNA	67	0	0	(67)
		Poly$(A)^+$ RNA	65	1	0	(86)
	Extended germ band	Cytoplasm	0	0	0	(47)
		Poly$(A)^+$ RNA	15	0	0	(34)

For cytoplasmic injections, cytoplasm was taken from wild-type embryos before pole cell formation (cleavage) or from embryos 1–2 h after the onset of gastrulation (extended germ band). Cleavage-stage RNA was isolated from 0–2-h embryos and extended germ band-stage RNA from 3–7-h embryos. The concentration of injected RNA, measured by absorbance at 260 nm, was 18 mg ml^{-1} for total RNA and 6–9 mg ml^{-1} for poly$(A)^+$ RNA preparations. The disappearance of *snake*- and *easter*-rescuing activities from cytoplasm begins at the onset of gastrulation (3.5 h) and falls off steadily to the value shown here 1–2 h later. The extended germ-band RNA was made from 3–7-h embryos, which should be a mixture of embryos that still have significant cytoplasmic rescuing activity and those that do not.

dramatically rescued the *snake* phenotype; the injected embryos developed filzkörper and ventral denticle bands (Fig. 2). The observed rescue is not due to some non-RNA contaminant, because the purified rescuing activity is protease-insensitive, RNase-sensitive and alkali-sensitive (Table 2).

To test whether the rescuing RNA is mRNA, the cytoplasmic RNA was separated on oligo(dT)-cellulose into poly$(A)^+$ and poly$(A)^-$ fractions, and both were tested for rescuing activity. The rescuing activity was recovered exclusively in the poly$(A)^+$ fraction; the *snake*-rescuing RNA is therefore polyadenylated and most probably mRNA (Table 2).

The phenotypic response seen depends on the concentration of the injected RNA. Injection of high concentrations of poly$(A)^+$ RNA restores the complete range of dorsal–ventral pattern elements in *snake* embryos. Although we have not observed hatching, many of these larvae have a full set of ventral denticle belts of normal width, and they exhibit movement inside the egg case. As the concentration is decreased, most rescued embryos have either clearly narrowed ventral denticle belts or develop only filzkörper. Another drop in concentration produces embryos which do not form ventral denticles, but still develop filzkörper. With yet further decreases in RNA concentration, the fraction of injected embryos developing filzkörper falls (Fig. 3). Thus, the highest degree of 'ventralness' achieved is proportional to the concentration of rescuing RNA, with a continuous increase in the qualitative nature of the response over a 50-fold range of RNA concentration. This dose–response curve for *snake* is the biochemical correlate of gene dosage studies with *dorsal*, where the presence of ventral structures is a function of the number of copies of the dl^+ gene[8,14].

The measurement of the dose-dependence of the response makes it possible to compare concentrations of rescuing activity in different preparations. For example, because rescuing activity can still be detected in a 50-fold dilution of poly$(A)^+$ RNA, the absence of activity from the corresponding RNase-treated sample means that more than 98% of the rescuing activity in that sample is RNase-sensitive. As equivalent responses are seen with total RNA and a 10-fold more dilute sample (in mg ml^{-1}) of poly$(A)^+$ RNA, the poly$(A)^+$ fraction is roughly 10-fold enriched in *snake*-rescuing RNA.

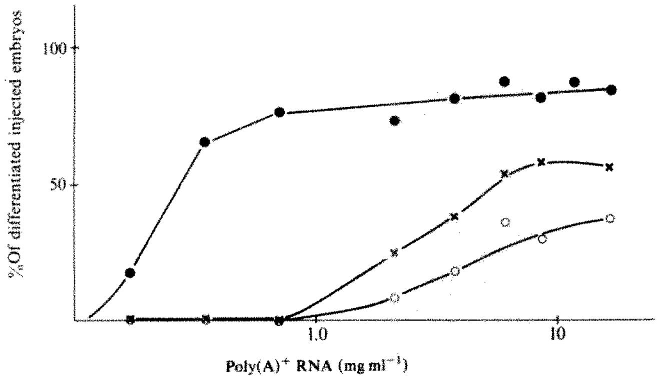


Fig. 3 Dose–response relationship for rescue of *snake* by poly$(A)^+$ RNA. At 0.2 mg ml^{-1} poly$(A)^+$ RNA, filzkörper (●) are developed by 40% of the differentiated injected embryos. At a 10-fold higher concentration, ventral denticles (×) (in addition to filzkörper) are developed by 40% of the differentiating embryos. At even higher RNA concentrations, a high percentage of embryos show a normal cuticular pattern (○), characterized by a full set of thoracic and abdominal ventral denticle belts of normal width in addition to filzkörper and head structures. The poly$(A)^+$ RNA fraction injected was purified by only one cycle of binding to oligo(dT)-cellulose and certainly still contains ribosomal RNA. The concentrations given here, measured by UV absorbance, should therefore be considered as relative, and are not directly comparable with the *in vivo* concentration of poly$(A)^+$ RNA. Each point represents the mean of at least 20 differentiated embryos.

Rescue of other dorsalizing mutants

Table 1 shows that six of the eight third-chromosomal dorsalizing maternal-effect mutants can be partially rescued by the injection of wild-type cytoplasm, with five loci responding strongly enough to develop ventral denticles. All five of these strongly responding loci (*snake, tube, easter, Toll* and *pelle*) are rescued not only by cytoplasmic injection but also by injection of RNA from cleavage stage wild-type embryos. In each case, the rescuing RNA is enriched in the poly$(A)^+$ fraction and is therefore probably mRNA. The rescuing RNA is locus-specific: while poly$(A)^+$ RNA isolated from *snake* embryos does not rescue *snake* embryos, the same preparation does rescue embryos mutant for *tube, easter, Toll* and *pelle.*

Each mutant shows a characteristic degree of response to injected RNA, which shows some parallels with the response of each mutant to cytoplasm. Of the three loci studied in greatest detail (*snake, tube* and *easter*), *snake* responds most strongly to injection of both cytoplasm and RNA (Table 3). The *in vivo* concentration of total RNA is 18 mg ml^{-1} (ref. 15), comparable to the concentration of total RNA injected in the experiment shown in Table 3. Comparing the rescue obtained with cytoplasm and total RNA, it is clear that a large amount of the *snake*- and *tube*-rescuing activities are not recovered in purified RNA, while most of the *easter*-rescuing activity is retained in the RNA. We estimate that 10% of the *snake*- and *tube*- and 70% of the *easter*-rescuing activities are recovered in purified RNA.

The *easter*-rescuing RNA also apparently differs from both the *tube* and *snake* RNAs in its degree of polyadenylation. Both *snake* and *tube* RNAs are roughly 10-fold enriched in the poly(A)$^+$ fraction, while the *easter* RNA is only 3-fold enriched. This is supported by the observation that the poly(A)$^-$ fraction rescues *easter* only slightly more weakly than total RNA (data not shown).

The concentrations of the poly(A)$^+$ RNAs that rescue *snake*, *tube* and *easter* all decrease rapidly during early development. The *tube*- and *easter*-rescuing activities are barely detectable in poly(A)$^+$ RNA isolated from 3–7-h embryos and the rescuing activity for *snake* is 20-fold reduced (by comparison with the dose–response curve of Fig. 3). This loss of rescuing activity in RNA parallels the loss of *snake*- and *easter*-rescuing activities from cytoplasm after the onset of gastrulation. For *tube*, in contrast, cytoplasm from extended germ band stage donors continues to rescue as effectively as cleavage cytoplasm, although RNA isolated from that stage not longer rescues significantly.

Conclusions

Maternal mRNA in *Drosophila* includes messages for abundant proteins like histones, actin and tubulin which are needed in large amounts early in development, as well as a high sequence complexity class of less abundant messages[16–20]. Maternal mRNA could also code for proteins specifically required in early embryonic morphogenesis. Indirect evidence from several systems supports the hypothesis that maternal mRNA is a source of morphogenetic information. In *Smittia* embryos, for example, an RNase-sensitive component prevents double abdomen formation[21]. It has also been shown that poly(A)$^+$ RNA can restore the ability to form pole cells in UV-sterilized *Drosophila* embryos[22]. It is difficult, however, to assess the specificity of these experimental manipulations and their relation to normal pattern-forming processes.

The maternal-effect mutations described here each remove a single, genetically defined component required in embryonic pattern formation. The phenotypic rescue of these mutants by injection of RNA provides a specific assay to probe the molecular basis of the establishment of the embryonic dorsal–ventral pattern. As poly(A)$^+$ RNA isolated from cleavage wild-type embryos rescues *snake*, *tube*, *easter*, *pelle* and *Toll*, these five different RNAs are a normal storage form of the morphogenetic information from these genes.

It is reasonable to assume that the rescuing RNAs are the protein-coding transcripts from the respective mutant genes. In the case of *snake*, the molecular analysis of this hypothesis should be relatively straightforward, because deficiency mapping has localized the *snake* gene within the DNA cloned in the *rosy-Ace* region[23].

The availability of a purified rescuing substance provides a probe for studying the nature of this pattern-forming system. The dose–response relationship between the amount of RNA injected and the phenotypic response of *snake* embryos shows that the level of ventral development achieved in the embryo is a direct, continuous function of the amount of *snake*-rescuing RNA present in the embryo. The rescue responses of *tube* and *easter* show analogous dose–response relationships, although more RNA is required for the same level of response. Thus *snake*, *tube* and *easter* are all essential components of a system of graded, positional information, and, at limiting amounts of gene activity, the effective morphogen activity becomes proportional to the amount of that gene product.

The cytoplasmic rescuing activity of each gene has a unique set of characteristics, which must reflect their unique roles in the establishment of the dorsal–ventral pattern. Not only are there large, quantitative differences in the responses of the mutants to the injection of wild-type cytoplasm, but the molecular nature of the rescuing activity is also characteristic for each mutant. Because more than two-thirds of the cytoplasmic rescuing activity for *easter* is recovered in purified RNA, and as the presence of rescuing activity in cytoplasm is paralleled by the rescuing activity in RNA during development, we suggest that the cytoplasmic rescuing activity for *easter* is exclusively RNA. Only about 10% of the cytoplasmic rescuing activities for *tube* and *snake* are recovered in RNA. Because the RNA could have been subject to differential degradation during purification or after injection, the *snake*-rescuing activity could be either exclusively RNA or a mixture of RNA and protein. Cytoplasm from the extended germ band stage of wild-type embryos rescues the *tube* mutant phenotype (at this stage almost no rescuing activity in RNA can be detected), suggesting that there is also a non-RNA component of the rescue with younger cytoplasm. We have been unable to detect any response of mutant *dorsal* embryos to the injection of RNA, although the *dorsal* RNA is present in young embryos[24]. The response of *dorsal* embryos to cytoplasmic injection is relatively weak, so if the RNA were preferentially labile, or if RNA is only a small fraction of the normal rescuing activity, we might not have detected it in our assay. In contrast *spätzle* embryos also respond weakly to cytoplasmic injection, but are nevertheless rescuable by RNA (F. Müller-Holtkamp and H. Jäckle, personal communication).

The demonstration that a group of morphogenetic mRNAs is present in early wild-type embryos suggests that control of the translation of these mRNAs may be a significant aspect of the mechanism of establishing dorsal–ventral pattern. The investigation of this possibility will require specific molecular probes for both the RNAs and the protein products of these genes. Such probes should elucidate the interaction between the members of this defined group of gene products that give rise to the dorsal–ventral pattern.

We thank Liselotte Bokla for technical assistance, Felix Müller-Holtkamp and Herbert Jäckle for communicating unpublished results, and Renate Brodbeck for typing the manuscript. K.V.A. was supported by the Deutsche Forschungsgemeinschaft.

A role for clathrin light chains in the recognition of clathrin cages by 'uncoating ATPase'

Sandra L. Schmid, William A. Braell, David M. Schlossman & James E. Rothman

Department of Biochemistry, Stanford University Medical School, Stanford, California 94305, USA

A cycle of clathrin assembly and disassembly drives the formation of coated vesicles, intermediates in intracellular protein transport. The heavy chain of clathrin is needed for assembly, but the function of the clathrin light chains has remained obscure. An enzyme has now been purified which uses ATP hydrolysis to power the release of clathrin from coated vesicles, presumably recycling the coat protein for repeated rounds of vesicle budding. This 'uncoating ATPase' requires clathrin light chains for its action.

COATED vesicles have a central role in intracellular protein transport[1-3]. Clathrin, the major coat protein, forms a three-legged structure termed a triskelion[4,5] which can self-assemble into cages resembling coats[6-8]. Each triskelion contains three clathrin heavy chains of 180,000 molecular weight (180K) and three noncovalently bound light chains. The molecular weights of the light chains from different species and tissues varies between 30K and 40K (refs 9, 10). Two different light chains are present, LC_α (36K in bovine brain) and LC_β (33K in bovine brain), in a constant molar ratio of 1:2. Both types of light chain can rebind to the same site on heavy chains near the vertex[11-13] and are found randomly distributed among these sites[13].

The function of the light chains has been obscure. The lack of assays in which the *in vivo* functions of clathrin and other coated vesicle proteins are reconstituted has made it difficult to elucidate the role of these components in the clathrin-coated vesicle cycle of assembly and disassembly which drives selective protein transport[14]. Therefore, we have attempted to reconstitute these processes. Here we report that light chains are required for the enzymatic disassembly of clathrin cages.

As an entry point into the cycle, we chose the uncoating step in which clathrin is released for use in repeated rounds of vesicle budding. We found that crude cytosol contained an ATP-dependent activity capable of releasing clathrin from coated vesicles and clathrin cages[15]. Based on this assay, we purified to homogeneity the active 70K protein from bovine brain cytosol[16,17]. This protein, an 'uncoating ATPase', uses ATP hydrolysis to power the release of clathrin from coated vesicles (or from cages reconstituted from triskelions). Clathrin is released as trimers containing stoichiometric amounts of noncovalently bound uncoating ATPase. ATP is hydrolysed in a coupled fashion during this release. Uncoating protein will only hydrolyse ATP when clathrin is also present; that is, uncoating protein is a clathrin-dependent ATPase. Assembled clathrin cages will elicit this ATPase activity but unassembled triskelions will not, as would be appropriate for an uncoating protein.

Clathrin-coupled ATP hydrolysis

The clathrin cage-dependent ATPase activity of the uncoating protein can be exploited as an assay to determine the structural aspects of clathrin needed for its recognition as a substrate. To test for a possible requirement for light chains, we prepared clathrin cages that either contained or lacked light chains, and tested these as substrates for uncoating ATPase.

Figure 1 is an SDS-polyacrylamide gel of these various clathrin substrates and demonstrates the selective removal of light chains in the appropriate forms of clathrin. Heavy chains free of detectable light chains were prepared by limited proteolysis[18,19] of clathrin cages using chymotrypsin or elastase (Fig. 1, lane *b*), or from triskelions following extraction of light chains with NaSCN (Fig. 1, lane *h*) according to Winkler and Stanley[12]. Light chain-depleted coated vesicles (Fig. 1, lane *f*) could be similarly prepared by limited proteolysis using chymotrypsin. Both proteolysis and extraction were used because recent evidence[12] shows that clathrin heavy chains prepared by limited proteolysis lack native assembly properties. Light chains will bind back to light chain-depleted 'heavy chain' cages with high affinity in near stoichiometric amounts to form 'reconstituted' cages, as reported previously[11-13,18]. The heat-stable light chains (Fig. 1, lane *d*) were prepared from supernatants of boiled clathrin[18,21]. Reconstituted cages were prepared by incubating these light chains with chymotrypsin-digested cages (Fig. 1, lane

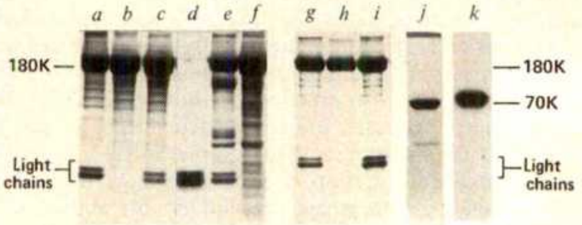

Fig. 1 SDS-polyacrylamide gel of clathrin substrates. Clathrin was purified from bovine brain by the method of Schook *et al.*[23] as previously described[16]. Lanes *a*, *g*, empty cages (12 μg) prepared by overnight dialysis of clathrin (1 mg ml^{-1}) into buffer A (20 mM methane ethane sulphonate, 2 mM $CaCl_2$, 1 mM EDTA *p*H 6.2) at 4 °C and preincubated in buffer B (40 mM HEPES, 75 mM KCl, 4.5 mM MgOAc, 0.8 mM dithiothreitol *p*H 7.0) as described previously[17]. Lane *b*, chymotrypsin-digested cases (12 μg) prepared by incubation of empty cages (1 mg ml^{-1}) in buffer A with 1.5 μg ml^{-1} TLCK-treated α-chymotrypsin (Sigma) for 45 min at 25 °C. Digestions were stopped by addition of phenylmethylsulphonyl fluoride (PMSF) to 1 mM. Chymotrypsin-digested cages were washed twice by centrifugation in a Beckman Airfuge at 100,000 *g* for 10 min and resuspended in buffer A containing 1 mM PMSF. Lane *c*, reconstituted chymotrypsin-digested cages (12 μg) prepared by recombination with light chains as described previously[18,11]. A ratio of 1:0.4 (w/w) heavy chains to light chains (~2-fold molar excess of light chains) was used to obtain stoichiometric reconstitution of light chains. Lane *d*, clathrin light chains (4 μg) prepared by boiling purified clathrin as previously described[18,21]. Lane *e*, coated vesicles (15 μg) purified from bovine brain using D_2O-Ficoll gradients as described by Pearse[24]. Lane *f*, chymotrypsin-digested coated vesicles (15 μg) prepared as described for chymotrypsin-digested empty cages. Lane *h*, clathrin heavy chains (10 μg) derived from NaSCN-extracted triskelions exactly as described by Winkler and Stanley[12]. Lane *i*, reconstituted SCN$^-$-extracted cages (12 μg) prepared by recombination with light chains, as described for lane *c*. Lane *j*, Coomassie blue stained gel and lane *k*, corresponding autoradiograph of ^{3}H-labelled uncoating ATPase (3 μg) prepared by the procedure of Tack *et al.*[22], as described in Fig. 4 legend. SDS-polyacrylamide gel electrophoresis minigels shown were 10% acrylamide and 3.5 cm in length. Samples were boiled in sample buffer and electrophoresed as described by Laemmli[25]. Gels were stained with Coomassie blue.

c) and SCN$^-$-extracted heavy-chain cages (Fig. 1, lane *i*). These various substrates were tested for their ability to elicit ATP hydrolysis by the uncoating enzyme.

Figure 2*a* shows the clathrin-dependent ATP hydrolysis by uncoating protein when intact cages are provided as substrate. The very low rate of clathrin-independent ATP hydrolysis (< 10% of the total) has been subtracted[17]. When cages depleted of light chains (by limited chymotrypsin digestion) were assayed (Fig. 2*a*), little or no hydrolysis was detected above enzyme-only backgrounds. To ensure that this difference was due to removal of light chains and not to some other effect of chymotrypsin, we determined whether adding back light chains would restore clathrin function. We found indeed that reconstitution with light chains quantitatively restored clathrin-dependent ATP hydrolysis (Fig. 2*a*). Uncombined light chains, added in equivalent amounts, did not elicit ATP hydrolysis (Fig. 2*a*). Qualitatively, but not quantitatively, the same results were obtained when we tested cages depleted of light chains by SCN$^-$ extraction (Fig. 2*b*). Again, clathrin function was restored on recombination with light chains (Fig. 2*b*).

The greater residual activity in Fig. 2*b* compared with Fig. 2*a* could be explained by a greater residue of light chains in the SCN$^-$-extracted clathrin, not easily detectable by Coomassie blue staining. To test this, we prepared ^{3}H-labelled clathrin by reductive methylation[16] and used this clathrin to prepare light chain-depleted cages as described above. Even though no residual light chains were detected in stained gels (Fig. 3, lanes *b*, *c*), autoradiography revealed that the SCN$^-$-extracted clathrin (Fig. 3, lane *f*) still retained up to 15% of its light chains (almost exclusively LC$_B$). No such residue could be detected in the chymotrypsin-treated heavy-chain cages (Fig. 3, lane *e*).

The apparent requirement for light chains could be trivially explained if the light chain-depleted cages had dissociated in assay conditions, for we have already shown[17] that dissociated triskelions do not elicit ATP hydrolysis. That the various cage substrates remain assembled during incubation to a comparable degree is demonstrated in Table 1*a*.

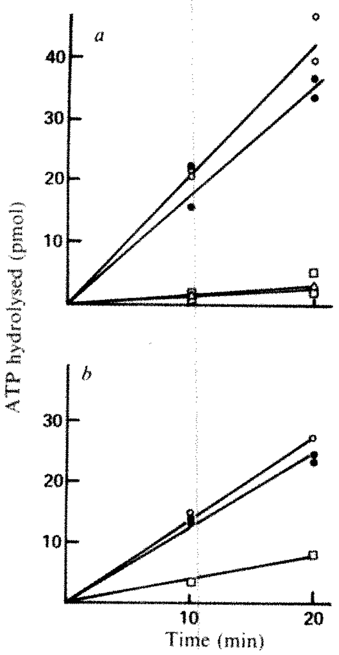

Fig. 2 ATPase activity of uncoating ATPase using various clathrin substrates. ATPase assays were performed as previously described[17]. Each assay contained 160 pmol ^{3}H-ATP, 4 μg clathrin substrate (prepared as described in Fig. 1 legend) or 1.5 μg of free light chains, and 0.2 μg uncoating ATPase in 20 μl buffer B. Data were corrected for backgrounds as described elsewhere[17] and thus reflect clathrin-dependent levels of ATP hydrolysis. Substrates used in *a*: empty cages (●), chymotrypsin-digested empty cages (□), free clathrin light chains (△) and chymotrypsin-digested cages whose light chains had been restored (○). Substrates used in *b*: empty cages (●), cages formed from NaSCN-extracted clathrin (□) and those cages recombined with light chains (○).

Clathrin release from cages

Given that ATP hydrolysis indeed precedes and is a prerequisite of clathrin release[17], uncoating protein-facilitated cage disassembly should also be light chain-dependent. Table 1*b* demonstrates that cages depleted of light chains by chymotrypsin digestion are poor substrates for ATP-dependent dissociation by uncoating ATPase (25 ± 17% of untreated controls). However, when light chains are added back, the ability of the cages to be dissociated by uncoating ATPase is restored (79 ± 16% of untreated controls).

Light-chain dependence is less evident when SCN$^-$-extracted cages are used as substrate (41 ± 9% release relative to controls). Because a few ATP-dependent enzymatic 'hits' may well be all that is needed to disassemble the cages[16], this assay is likely to be much more sensitive to the presence of residual light chains than is the ATPase assay. The 15% residual light chains present in SCN$^-$-extracted cages (~16 light chains per clathrin cage) may therefore be sufficient to facilitate uncoating protein-catalysed cage fragmentation and ensuing clathrin release.

Uncoating ATPase and clathrin cages

The requirement of light chains in clathrin cages to elicit the ATPase activity of uncoating protein implies that they are needed for the productive association of uncoating protein with

Table 1 Release of clathrin cages as a function of their light-chain content

a, Spontaneous release	
Substrate	Clathrin released* (% of total)
Control cages	6.5 ± 1.4 (6)
Chymotrypsin-digested cages	14.6 ± 7.6 (5)
Chymotrypsin-digested cages recombined with light chains	13.7 ± 7.8 (5)
SCN$^-$-extracted clathrin cages	17.7 ± 6.6 (6)
SCN$^-$-extracted clathrin cages recombined with light chains	12.5 ± 4.6 (6)
b, Uncoating ATPase-promoted release	
Substrate	% Release (relative to control cages)
Control cages†	[100]
Chymotrypsin-digested cages	25 ± 17 (7)
Chymotrypsin-digested cages recombined with light chains	79 ± 16 (7)
SCN$^-$-extracted clathrin cages	41 ± 9 (5)
SCN$^-$-extracted clathrin cages recombined with light chains	71 ± 22 (7)

Uncoating assays were performed as described previously[16]. Each assay contained 10 μg of clathrin substrate (prepared as described in Fig. 1 legend), 3 μg of uncoating ATPase and 50 μM ATP in 50 μl buffer B. After incubation at 37 °C for 10 or 20 min, the reaction was stopped by addition of yeast hexokinase (to 10 U ml^{-1}) and glucose (to 5 mM) and centrifuged in a Beckman Airfuge, as described previously[16]. A sample of each supernatant (20 μl) was electrophoresed on 10% polyacrylamide minigels. Release of clathrin into the supernatant was quantitated as described elsewhere[14,16], from densitometric tracings of the 180K clathrin band on the Coomassie blue stained gels. In *a*, incubations were performed in the absence of uncoating enzyme to test the intrinsic stability of each cage substrate to incubations in assay conditions. In *b*, incubations contained 3 μg uncoating ATPase. The rate of ATP-dependent clathrin release is expressed relative to release from untreated cages in parallel incubations to allow comparison between experiments.

* Values are mean ± s.d.

† Uncoating protein-dependent clathrin release from control cages was 46.7 ± 25% ($n = 10$) during 10 min incubations in buffer B.

Table 2 Light chain-dependent association of uncoating protein with clathrin cages

Clathrin substrate	ATP	Uncoating protein bound (% of total)†
None	+	4.5 ± 2.2 (4)
	−	5.3 ± 1.6 (2)

Column elution profiles generated as described in Fig. 4 legend were quantitated by integration of void and included peaks. Data are expressed as the ^{3}H counts recovered in the void peak as a per cent of the total ^{3}H eluted. The mean ± s.d. from several independent experiments is shown. The number of experiments is given in parentheses.

* ATP regenerating system[15] was used instead of ATP.

† Recovered in the void volume of Biogel A1.5m.

cages. The uncoating protein plus bound ATP[17] must clearly interact with cages before ATP hydrolysis and subsequent clathrins release. This interaction could occur first, independently of light chains, followed by light chain-dependent ATP hydrolysis. Alternatively, light chains might be required for the initial recognition of cages by the uncoating enzyme–ATP complexes, leading to subsequent ATP hydrolysis and then clathrin release. To distinguish between these possibilities, we have devised a binding assay to detect any association between uncoating protein and clathrin cages and investigated whether we could detect any binding of uncoating protein to cages depleted of light chains.

^{3}H-labelled uncoating protein (specific activity 0.1–0.2 mCi per mg) was prepared by reductive methylation[22] and was fully active in both clathrin-dependent ATPase and ATP-dependent clathrin release assays (see Fig. 4 legend for details). Figure 1 shows a Coomassie blue stained SDS gel (lane *j*) and corresponding autoradiograph (lane *k*) of a preparation of ^{3}H-labelled uncoating ATPase. The uncoating ATPase was incubated with excess amounts of light chain-depleted clathrin cages with or without ATP, and the products were separated by gel filtration on Biogel A1.5m to distinguish free uncoating protein (^{3}H in the included volume) from that bound to clathrin (^{3}H in the void volume).

It is important to note that this assay will measure binding of uncoating protein to intact cages (when disassembly does not occur) as well as entry of uncoating ATPase into complexes with the released triskelions (when disassembly does occur), as both forms of clathrin elute in the void volume. Therefore, the assay measures any association between uncoating ATPase and clathrin, independent of clathrin release. As expected, incubation of ^{3}H-labelled uncoating protein with empty cages and ATP results in binding (Fig. 4*b*), in this case to the released triskelions (Table 1*b*). This binding does not occur in the absence of ATP (Fig. 4*a*), a condition in which clathrin is not released[16]. We showed previously[17] that preformed uncoating protein–ATP complexes can interact with cages, resulting in ATP hydrolysis. The lack of ATP-independent binding of uncoating protein to cages indicates that the ATP–uncoating protein complexes must form before interaction with cages.

When cages depleted of light chains (by chymotrypsin digestion) were used (Fig. 4*c*), little or no binding to cages occurred above minus clathrin background (Fig. 4*h*), even in the presence of ATP. Therefore, if a light chain-independent interaction of uncoating protein with clathrin cages does precede ATP hydrolysis and cage disassembly, we cannot detect it. ATP-dependent binding could be restored by adding back light chains to the chymotrypsin-treated cages (Fig. 4*d*). As with intact cages, this association represents uncoating protein present in complexes with released calthrin whose ability to be released was restored on recombination with light chains (Table 1*b*). Qualitatively similar results were obtained when we used cages prepared from SCN⁻-extracted heavy chains (Fig. 4*e*), and when these were recombined with light chains (Fig. 4*f*). Again, a greater residue of binding occurs when SCN⁻-extraction rather than proteolysis is used to deplete light chains. As expected, coated vesicles were also substrates for the formation of uncoating protein–clathrin complexes during uncoating (Fig. 4*g*). As with cages, selective chymotrypsin digestion of light chains from coated vesicles greatly reduced the yield of the released complexes (Table 2). Table 2 presents quantitative data on binding calculated as the per cent of ^{3}H-labelled uncoating protein recovered in the void volume.

Altogether, we have found no evidence for interaction of uncoating protein with light chain-free clathrin cages. These experiments suggest that light chains are required by uncoating protein for the initial recognition of clathrin cages as substrate.

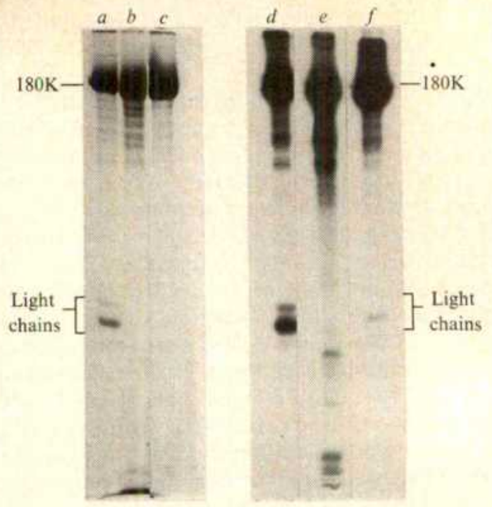

Fig. 3 SDS-polyacrylamide gel and corresponding autoradiograph of ^{3}H-clathrin substrates. ^{3}H-clathrin (~0.2 mCi per mg) was prepared by reductive methylation with formaldehyde and NaB[^{3}H]$_4$ as described previously[16]. ^{3}H-labelled empty cages were prepared by dilution of labelled clathrin with unlabelled clathrin to a final specific activity of 16,000 c.p.m. per μg and dialysis against buffer A as described in Fig. 1 legend. Chymotrypsin-digested cages and SCN⁻-extracted cages were prepared from ^{3}H-labelled empty cages or from the diluted ^{3}H-clathrin. Lanes *a–c*, Coomassie blue stained; lanes *d–f*, the corresponding autoradiograph. Lanes *a*, *d*, ^{3}H-labelled empty cages; lanes *b*, *e*, ^{3}H-chymotrypsin-digested cages; lanes *c*, *f*, ^{3}H-labelled SCN⁻-extracted cages. Each lane contained 25 μg of protein and 400,000 c.p.m.

Conclusions

Our studies of the mechanism of ATP-dependent uncoating in a cell-free system reconstituted from pure components has revealed that light chains are required on clathrin cages for the activation of uncoating ATPase. This is the case for all facets of its activity that we can presently measure—clathrin-dependent ATP hydrolysis, ATP-dependent clathrin release and ATP-dependent enzyme–clathrin complex formation. Two lines of evidence suggest that light chains are needed at an early stage in the uncoating reaction for initial recognition of clathrin cages

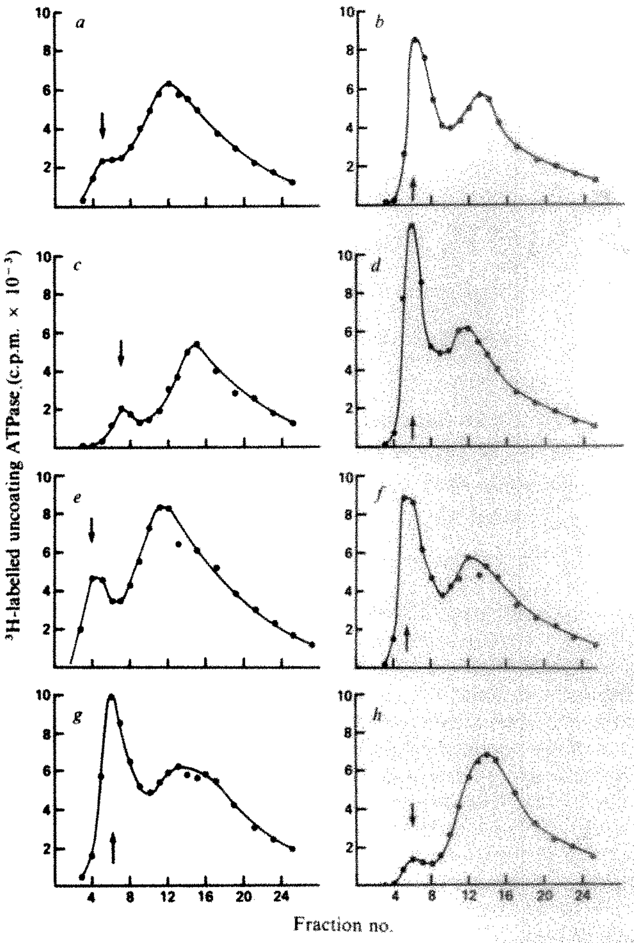

Fig. 4 Gel filtration assay for binding of ^{3}H-uncoating ATPase to clathrin substrates.

Methods: *a*, Empty cages in the absence of ATP which was replaced in the incubation by yeast hexokinase (10 U ml^{-1}) and glucose (5 mM); *b*, empty cages as substrate in the presence of ATP; *c*, chymotrypsin-digested cages, with ATP; *d*, chymotrypsin-digested cages recombined with light chains (with ATP); *e*, cages prepared from SCN$^-$-extracted clathrin; *f*, SCN$^-$-extracted clathrin cages after recombination with light chains; *g*, bovine brain-coated vesicles as substrate with ATP; *h*, incubation of uncoating ATPase in the presence of ATP, without any clathrin. The arrow indicates the void volume. Uncoating ATPase was tritiated using the Tack procedure for reductive methylation[22]. Typically, 150 μg of uncoating ATPase (1–2 mg ml^{-1}, 2.1 nmol) in 0.2 M Na borate *p*H 8.9 was incubated with 0.4 μmol formaldehyde and 0.1–0.2 μmol ^{3}H-NaBH$_4$ (Amersham, 8.7 Ci mmol^{-1}) for 10 min on ice. Free radiolabel was removed by exhaustive dialysis against two changes of 1,000 vols each of buffer B. ^{3}H-labelled uncoating ATPase (~ 0.1 mCi per mg) retained full ATPase and uncoating activities (data not shown) and was stable for 4–6 days at 4 °C and for several months after freezing in liquid N$_2$ and storage at −70 °C. Incubations contained 20 μg clathrin substrate, 1.3 μg of ^{3}H-labelled uncoating ATPase (diluted with unlabelled uncoating protein to achieve a final specific activity of ~30,000 c.p.m. per μg) and 1.25 nmol ATP in 25 μl of buffer B. After 20 min at 37 °C, incubation mixtures were chilled on ice and quickly loaded onto Biogel A1.5 m columns (15 × 0.3 cm) equilibrated in buffer B containing 0.5% bovine serum albumin (BSA) at 4 °C. Columns were eluted at 1.5 ml h^{-1}, collecting 55-μl fractions which were counted for ^{3}H. Representative elution profiles using various clathrin substrates are shown here. The ATP dependence of binding, as well as uncoating[16], varied with uncoating ATPase preparations but was high and reproducible following storage at 4 °C for 1–2 days or after being subjected to the discharging procedure described elsewhere[16]. We believe that ATP independence reflects a variable amount of tightly bound nucleotide obtained on elution of the enzyme from ATP–Sepharose with ATP during purification[16].

by the uncoating enzyme. First, we can detect no interaction of uncoating protein with cages lacking light chains (Fig. 4, Table 2) and second, light chains are required for ATP hydrolysis (Fig. 2), which precedes clathrin release[16,17]. In the simplest view, uncoating protein would bind directly to the light chains on the surface of cages. However, as free light chains do not substitute for whole clathrin (Fig. 2), either light chains exist in a different conformation (recognized by uncoating protein) when bound to heavy chains, or sites on both heavy and light chains are needed for productive binding, or both. In any case, it is clear that light chains are required for the function of clathrin in enzymatic uncoating.

The reason clathrin has two distinct species of light chains is unknown. We found that cages reconstituted so as to contain exclusively LC$_\alpha$ or LC$_\beta$ (refs 11, 12) are equivalent to native cages as substrates for ATPase activity (W.A.B. and J.E.R., unpublished data). This suggests that the functional distinction between LC$_\alpha$ and LC$_\beta$ cannot be detected by the limited assays available, and that additional roles of these components remain to be elucidated. For example, light chains may well function in other stages of the clathrin-coated vesicle cycle. If so, this will only become apparent through the creation of assays that represent reconstitutions of these steps. Such an approach will lead to an understanding of how clathrin and coated vesicles function in the dynamic process of membrane transport.

We thank the Helen Hay Whitney Foundation and Jane Coffin Child Memorial Fund for their support (of D.M.S. and W.A.B., respectively). This research was carried out under NIH grant GM 25662.

Mutations that alter the DNA sequence specificity of the catabolite gene activator protein of *E. coli*

Three mutations that alter the DNA sequence specificity of the catabolite gene activator protein (CAP) from AA-TGTGA--T---TCA-ATW to AA-TGTAA--T---TCA-ATW have been isolated. All three mutations affect the same amino acid of CAP, glutamic acid 181. We propose that it is this amino acid of CAP that makes contacts with base pairs 7 and 16 of the symmetrical recognition site.

THE catabolite gene activator protein (CAP; also referred to as the cyclic AMP receptor protein, CRP), when complexed with cyclic AMP, binds to specific DNA sites at or near promoters, where it stimulates the initiation of RNA synthesis[1,2]. Figure 1 shows 18 DNA sequences that have been demonstrated to bind to CAP by nuclease protection analysis. The last line presents a consensus sequence (AA-TGTGA--T---TCA-ATW), indicating those bases that are conserved at a statistically significant frequency. The chemical-protection[3,4] and genetic[5–8] data confirm that the bases specified in this sequence are in fact important points of contact between DNA and CAP.

Ultimately we hope to understand how, at the atomic level, each base pair (bp) in the consensus DNA site is recognized by CAP. Our approach here is to isolate a mutationally altered CAP (CAP′) that binds tightly and selectively to a DNA site that differs by one nucleotide from the wild-type recognition site. A mutation that confers this phenotype will do so by altering, directly or indirectly, the contact made by CAP with the base that differs in the 'new' and wild-type recognition sites (Fig. 2). In principle, therefore, this approach has the potential to define individual direct contacts between CAP and DNA.

We describe here a genetic selection that yields mutations of this type. We also describe the characteristics and DNA sequences of three mutations isolated using this selection. The implications of the results for CAP–DNA recognition, and for protein–DNA interaction in general, will be discussed briefly here and in detail elsewhere[9].

Selection procedure

The strategy we used relies on two facts: (1) *lac*, *mal*, *ara*, *rbs*, *tna*, *uhp* and *glpT* are all genes or operons whose expression is dependent on CAP plus cyclic AMP[1,10]. Each of these contains an intact wild-type site for recognition by the CAP–cyclic AMP complex. (2) The *lacL8* mutation is a $G \rightarrow A$ nucleotide substitution within the *lac* recognition site for CAP (Fig. 3)[5,6]. CAP binds to the *lacL8* sequence only $\frac{1}{70}$th as tightly as to lac^+; therefore, strains bearing the *lacL8* mutation exhibit a Lac$^-$ phenotype[5,11].

The objective of our experiments was to obtain a mutationally altered CAP (CAP′) able to bind tightly and selectively to the *lacL8* sequence. We reasoned that the desired class of mutations would confer two identifiable properties: (1) a pleiotropic defect for recognition by CAP of wild-type sequences and (2) the ability to activate *lacL8* (Fig. 2).

We have devised a genetic selection that, on a single plate, imposes both of these criteria. Our selection consists of two steps. In the first step, we select from a *lacL8* parent a pool of 1,000–5,000 independent colonies defective for activation by CAP of the wild-type *uhp* and *glpT* sequences. To do this, we select resistance to the antibiotic phosphonomycin[10,12] on plates containing cyclic AMP. In the second step, we identify the rare colonies within this pool that exhibit a Lac$^+$ phenotype (that is, those that activate *lacL8*). To identify these, the selection with phosphonomycin/cyclic AMP is performed on Lac-EMB (ref. 13) indicator plates; Lac$^+$ colonies are purple on this medium, whereas the Lac$^-$ parent is white.

Isolation of crp′

A population of *lacL8 gal thi* cells was mutagenized by exposure to UV light, grown for 6.5 h at 37 °C and plated (1×10^8 cells) onto selective media of the type described above. Selective plates were Lac-EMB, to which were added 5 μM phosphonomycin, 0.5 mM glucose 6-phosphate, 0.5 mM glycerol (to de-repress *uhp* and *glpT*, respectively), 0.3 mM cyclic AMP and 3 mM thiamine. Eight independent mutageneses/selections were performed, resulting in the isolation of approximately 20,000 independent phosphonomycin-resistant colonies.

Among these, two purple (Lac$^+$) colonies were detected. These isolates, designated *crp′L8-1* and *crp′L8-2*, were found to be

Fig. 1 DNA sites known to bind to CAP. 18 DNA sequences are shown to which CAP has been demonstrated to bind using nuclease-protection experiments; the last line is a consensus sequence indicating those bases that are conserved at a statistically significant frequency ($P < 0.05$). (W indicates a position that can be either A or T.) The sequences were aligned, and statistical significance calculated, by the method of Ebright[36], where 11 of these sequences were tabulated (compare ref. 2). References for the sequences are supplied in ref. 36, except for *malT* (ref. 37), *araE* (ref. 38), *tna* (ref. 39), *bglR* (A. Wright, A. Reynolds and S. Le Grice, personal communication), *ilvB* (ref. 40), *crp* (ref. 41) and *crp*-site 2 (ref. 41).

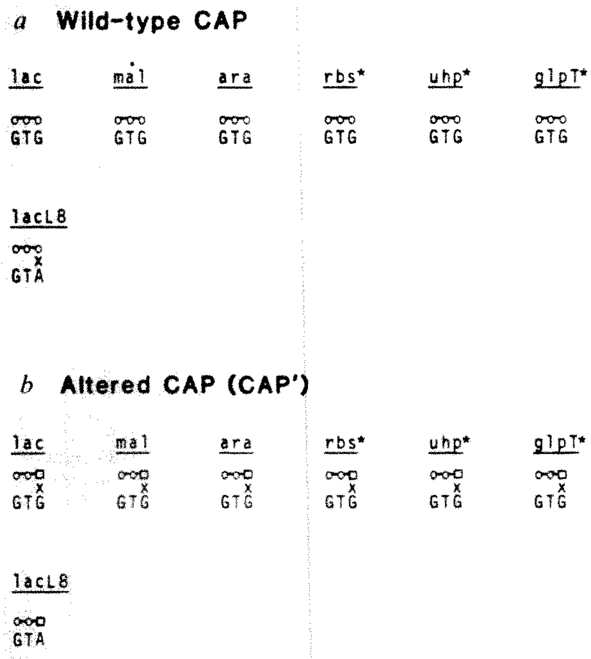

Fig. 2 Logic of the experiment. *a*, Line 1: Wild-type CAP binds tightly to sites contained in *lac*$^+$, *mal*, *ara*, *rbs*, *tna*, *uhp* and *glpT* (refs 1, 2, 10). The sequence GTG is the most highly conserved portion of the consensus recognition site (Fig. 1), the three nucleotides being present in, respectively, 18, 13 and 17 of the 18 known sites. (The actual sequences of *rbs*, *uhp* and *glpT* are not known, but we expect that they will contain this triplet.) The contacts CAP makes with the three nucleotides are illustrated schematically as circles. Line 2: Wild-type CAP does not interact tightly with the *lacL8* site, which contains a G → A nucleotide substitution at position '3' (refs 5–7). The low affinity (1/70th that for *lac*$^+$)[6,11] apparently reflects the inability of the contact CAP makes with position 3 to be satisfied by A. *b*, The object of our experiments was to obtain a mutationally altered CAP, CAP', that exhibits the opposite specificity of binding: that is, defective for interaction with wild-type sequences (line 1), but binds tightly to *lacL8* (line 2). A mutation of this type will alter, directly or indirectly, the contact CAP makes to position 3—changing this contact from one that confers specificity to G, as in wild-type CAP, to one that confers specificity to A.

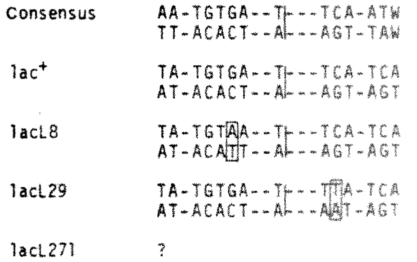

Fig. 3 Sequences of wild-type and mutant *lac* recognition sites. Line 1 shows the consensus site (Fig. 1), indicating both DNA strands. (W indicates a position that can be either A or T.) The axis of 2-fold symmetry in the sequence is located between positions 11 and 12. Lines 2–5 show the *lac*$^+$ site, which is very similar to the consensus, and three mutant recognition sites. Note that the base changes in *lacL8* and *lacL29* (boxed) are symmetrically identical[5,6]. *LacL271* is a *lac* promoter mutation isolated using the same selection that yielded *lacL8* and *lacL29* (ref. 42), but not yet sequenced (sequence analysis presently in progress; W. Reznikoff, personal communication). By two genetic criteria, the mutation is a substitution within the recognition site for CAP: (1) inability to recombine with the *lacL1*[5,6] deletion, and (2) same β-galactosidase level as *lac*$^+$ in a *crp*$^-$ genetic background[42]. However, from its β-galactosidase level in a *crp*$^+$ background (304 units), it is clear that *lacL271* is a different nucleotide substitution from either *lacL8* or *lacL29* (93 and 109 units, respectively). Our results in Table 2 substantiate this point.

Fig. 4 Sequences of the *crp'* mutations. The amino acid sequence of CAP between residues 169 and 191 is illustrated[43,44], along with the amino acid substitutions in CAP'L8-1, CAP'L8-2 and CAP'L29-2, as deduced from the DNA sequences. All three mutations affect glutamic acid 181 (GAA) of CAP, substituting it by lysine (AAA), leucine (TTA) or valine (GTA). The positions of α-helices E and F in the crystallographic structure of CAP[17] are also indicated.

Mal$^-$ Ara$^-$ Rbs$^-$ Tna$^-$ Uhp$^-$ and GlpT$^-$, as assessed on indicator plates (Table 1). To quantify the effect on Lac expression in the two isolates, β-galactosidase assays were carried out. Table 1 shows that the two isolates exhibit 2.2 and 34 times the β-galactosidase level of the *lacL8 crp*$^+$ parent. Note that the β-galactosidase level in the *lacL8 crp'L8-2* isolate (3,200 units) actually exceeds that obtained in a *lac*$^+$ *crp*$^+$ strain (2,350 units, Table 2). This suggests that CAP'L8-2 may interact with the *lacL8* site equally or more tightly than wild-type CAP interacts with the *lac*$^+$ recognition site.

A selection identical in scale and protocol was carried out using the *lacL29* (refs 5, 6) mutation (Fig. 3). In this case, from ~18,000 phosphonomycin-resistant colonies, two Lac$^+$ colonies were isolated. One isolate was found to be Mal$^+$ Ara$^+$ Rbs$^+$ Tna$^+$ GlpT$^+$, and therefore was not characterized further. The other isolate, designated *crp'L29-2*, exhibited a pleiotropic Rbs$^-$ Tna$^-$ Uhp$^-$ GlpT$^-$ phenotype (Table 1). Table 1 shows that the *lacL29 crp'L29-2* isolate has 24 times the β-galactosidase level of the *lacL29 crp*$^+$ parent (a level comparable with that obtained in an isogenic *lac*$^+$ *crp*$^+$ strain).

Mapping and transfer to a phage vector

The phage λY1079 (λ *Bam*λ1° *srI*λ[1, 2]Δ cIts857 *int crp*$^+$; S. Adhya, personal communication) carries a 3.5-kilobase (kb) *Bam*HI insert containing the complete *crp* structural gene and promoter. Because λY1079 is *int*$^-$, it integrates into and excises from the chromosome only by homologous recombination within the 3.5-kb insert. We have used this property to demonstrate that the *crp'* mutations in fact map within *crp*. This was done in two ways.

In the first type of experiment, λ$^-$ recombinants ('cures') were selected from *crp'*/λY1079 lysogens by cultivation at 40 °C. For each *crp'* allele, approximately one-half of the cures were Rbs$^+$ (that is, *crp*$^+$), and inspection of 16 of these verified that all were also Lac$^-$. These data demonstrate that both the Lac$^+$ and Rbs$^-$ phenotypes of the three mutants are contained within the region defined by the 3.5-kb *crp* insert of λY1079.

In the second type of experiment, recombinant phage that carry *crp'* were isolated. This was accomplished by thermoinduction of *crp'*/λY1079 lysogens. The procedure gave rise to mixed lysates, each containing approximately equal numbers of λ*crp*$^+$ and λ*crp'*. It was possible to identify λ*crp'* either by plaque colour on a lawn of *lacL8* (or *lacL29*) cells on Lac-tetrazolium plates, or by inability to complement the Rbs$^-$ phenotype of *crp'L29-2*.

Effects on DNA sites

Table 2 presents the results of analyses with the *lac*$^+$ and three mutationally altered *lac* recognition sites. The striking result is that each CAP' interacts approximately equally well with *lacL8* and *lacL29*. Note from Fig. 3 that the base changes in *lacL8* and *lacL29* are symmetrically identical: each is a G → A substitution located 5 bp from the axis of 2-fold symmetry in the recognition site (that is, at base pairs 7 and 16)[6]. The ability of CAP′ to interact tightly with both the *lacL8* and *lacL29* sequences, but not with wild-type sequences (Table 1), indicates that the contact made by CAP to base pair 7 of the recognition site may be identical in detail to the contact it makes to the symmetrical position, base pair 16. The simplest interpretation of the data is that in the CAP–DNA complex the 2-fold axis of the CAP dimer is superimposed on the 2-fold axis of the recognition site (see ref. 9 for detailed discussion).

The control experiments which support this conclusion are presented in Table 2. Column 3 shows that each CAP′ interacts with *lacL271* even less effectively than does wild-type CAP. By both biochemical and genetic criteria, *lacL*271 is a mutation within the recognition site for CAP in *lac*, but is a different nucleotide substitution from either *lacL*8 or *lacL*29 (Fig. 3, legend). The inability of CAP′ to suppress the *lacL271* defect, despite its strong effects on *lacL8* and *lacL29*, is evidence for allele specificity. Thus, the data indicate that CAP′ alters, and does not merely relax, DNA sequence specificity.

Table 2, column 4, shows that each CAP′ is defective for interaction with the wild-type lac^+ sequence. In the case of CAP′L8-1, the quantitative defect for interaction with lac^+ is fivefold. CAP′L8–2 and CAP′L29-2 show a more modest defect, 1.3–1.5-fold, but these effects are reproducible. We point out that the *in vivo* concentration of CAP may approach or exceed the amount required to saturate the lac^+ site. Thus, our *in vivo* data may underestimate the actual defect in affinity of CAP′ for lac^+. The greater defect observed for the interaction of CAP′L8-2 and CAP′L29-2 with the rbs^+ site (7.5- and 2.5-fold; R.H.E. and J. Lopilato, unpublished data) is consistent with this possibility. A rigorous determination of this parameter must await measurement of the binding affinities *in vitro*. Such experiments are in progress.

CAP′ requires cyclic AMP

To assess *in vivo* the dependence of CAP′ on cyclic AMP, we have introduced a cya^- (adenylate cyclase) mutation into each *crp′* strain. Table 3 shows that, in each case, introduction of the cya^- mutation reduced β-galactosidase expression to the basal level of ~130 units. These data demonstrate that, like wild-type CAP, CAP′ requires cyclic AMP, which suggests that the *crp′* mutations alter only DNA sequence recognition, and not the binding of cyclic AMP to CAP or the cyclic AMP-mediated allosteric change.

Fine-structure mapping

To map more precisely the locations of the *crp′* mutations, we used a deletion mapping system, the details of which will be discussed elsewhere. Briefly, the system consists of 20 deletions generated by *Bal*31 (ref. 14) digestion, starting either at the *Hpa*I site located upstream of the *crp* promoter, or at the *Bcl*I site located within *crp* at the position corresponding to isoleucine 51. In addition to the deletions generated *in vitro*, the mapping experiments have also used a *lacZ* insertion–deletion mutation, *D2*, located at the 3′ end of the *crp* gene.

To map the mutations, spot crosses on Rbs-minimal plates were carried out between HfrG6 Δ*crp* strains and the three F^- *crp′* recipients. The data indicate that all three *crp′* mutations map to a single deletion interval within *crp*. This interval, defined by deletions *T22* and *D2*, corresponds to amino acids 122–192 of CAP.

DNA sequence analysis

The entire DNA nucleotide sequence of the region defined by deletions *T22* and *D2* was determined for each mutation. The source of DNA for this analysis was the 3.5-kb *Bam*HI *crp* fragment purified directly from high-titre stocks of λ*crp′*. The sequences were determined by the method of Maxam and Gilbert[15].

Remarkably, all three mutations affect the same codon of *crp*: GAA, corresponding to glutamic acid 181 of CAP (Fig. 4). The *crp′L8-1*, *crp′L8-2* and *crp′L29-2* mutations convert this codon to AAA (lysine), TTA (leucine) and GTA (valine), respectively. No other changes were detected in the appropriate deletion interval or up to 60 bp to either side. This result demonstrates that it is possible to alter the specificity of CAP by a single amino acid substitution. It indicates further that residue 181 is important in determining the specificity of CAP for lac^+ compared with *lacL8* or *lacL29*.

Table 1 Pleiotropic effects of *crp′*

Markers	Lac	Mal	Ara	Rbs	Tna	Uhp	GlpT
Δ*gal165 lacL8* crp^+	−(93)	+	+	+	+	+	+
Δ*gal165 lacL8 crp′L8-1*	+(209)	−	−	−	−	−	−
Δ*gal165 lacL8 crp′L8-2*	+(3,200)	−	−	−	−	−	−
Δ*gal165 lacL29* crp^+	−(108)	+	+	+	+	+	+
Δ*gal165 lacL29 crp′L29-2*	+(2,620)	+	+	−	−	−	−

+ Indicates wild-type phenotype as determined in plate tests; − indicates a defect in expression. The numbers in parentheses are induced β-galactosidase levels expressed in Miller units[32] and are the means of three independent determinations. For *crp′L8-2* and *crp′L29–2*, we have also determined β-galactoside levels in Δ*lac* strains containing a rbs^+–*lacZ* operon fusion (R.H.E. and J. Lopilato, unpublished data). The quantitative data verify that the *crp′* strains are defective for *rbs* expression (144 and 516 units, compared with 1,070 for crp^+).

Methods: Strains contained the Δ*gal165* mutation in order to avoid the complicating effects of *gal* expression, which is CAP-regulated[1,2], on the Lac phenotype. (Lactose is metabolized to glucose and galactose; therefore, in gal^+ strains, colour on Lac indicator plates reflects a composite of lactose and galactose metabolism.) Each strain also contained a thi^- mutation. Lac, Mal, Ara and Rbs phenotypes were assessed on tetrazolium[33] indicator plates; − indicates dark-red colour. Tna phenotype was determined in spot tests on tryptone media using Kovacs' reagent (ref. 34 and J. Felton, personal communication); − in this case refers to white colour. Uhp and GlpT phenotypes were determined by sensitivity to phosphonomycin (ref. 10) and GlpT was independently verified by growth on α-glycerophosphate. β-Galactosidase assays were carried out according to the method of Miller[32], using cells grown in the presence of 1 mM isopropyl-1-thio-β-D-galactoside (IPTG) and 3 mM thiamine.

Model building has previously implicated this region as being involved in DNA recognition. Figure 4 shows that amino acid 181 is the second residue of α-helix F of CAP. In the crystallographic structure of CAP, this helix protudes from the surface of each of the two subunits of the dimer, and is separated across the molecular 2-fold axis by 34 Å from the same helix of the other subunit[16,17]. These features led Steitz and co-workers to propose that helix F could interact with two successive major grooves of either left[16] or right-handed[18] B-DNA. In support of this analysis, is has been shown that the conformation of the 24 α-carbon atoms comprising helices E and F is similar to that of a helix-turn-helix motif contained in both cro and λ-repressor[19,20]. As in the case of CAP helix F, the second of the two α-helices in cro and repressor protrudes from the surface of the molecule, is separated from the same helix in the other subunit by 34 Å across the 2-fold axis, and therefore is a potential candidate to interact with base pairs in successive major grooves of DNA[21,22]. Furthermore, the amino acid sequences of the relevant regions show striking homologies in CAP, cro and repressor, and also in a variety of other prokaryotic DNA-binding proteins[23–25]. From these theoretical considerations, it has been proposed that the helix-turn-helix motif (helices E and F in CAP) is central to the sequence-specific interactions of CAP and other proteins to DNA. The sequences of our three mutations provide strong support for this hypothesis.

In addition, biochemical experiments support the idea that this part of CAP is important for interaction with DNA. Proteolysis by *Staphylococcus aureus* V8 protease removes amino acids 172–209 of CAP, while leaving the rest of the molecule intact[26,27] This treatment has been shown to destroy the DNA-binding activity of CAP, and has been interpreted to imply that amino acids 172–209 may participate in contacts to DNA.

Glutamic acid 181

We have demonstrated that substitution of glutamic acid 181 by lysine, leucine or valine alters the DNA sequence specificity

Table 2 Effects of CAP′ on wild-type and mutant recognition sites

Markers	*lacL8*	*lacL29*	*lacL271*	*lac*$^+$
crp$^+$	93	109	304	2,350
crp′L8-1	275	544	141	504
crp′L8-2	3,110	3,560	189	1,810
crp′L29-2	3,920	2,710	179	1,500

The data are β-galactosidase levels (means of four independent assays) determined as in Table 1. Strains were constructed in two steps. In step one, *lacL8*, *lacL29*, *lacL271* or *lac*$^+$ recipients were lysogenized with λY1079 *crp′* (see text). In step two, λ$^-$ cures were selected from the lysogens by cultivation at 40 °C. Rbs$^-$ (that is, *crp′*) cures were identified on Rbs–tetrazolium agar and were verified to be Uhp$^-$ GlpT$^-$, and where appropriate also Mal$^-$ and Ara$^-$. In addition to the markers indicated, the strains also contained *Δgal165* and *thi*.

Table 3 Dependence of CAP′ on cyclic AMP

Markers	*cya*$^+$	*Δcya854*
lacL8 crp′L8-1	196	132
lacL8 crp′L8-2	2,250	138
lacL29 crp′29-2	2,220	127

The data are the means of four assays of β-galactosidase (method in ref. 32). Cells for the assays were grown in media containing 1 mM IPTG, 3 mM thiamine, 0.5 mM isoleucine and 1.2 mM valine. *Δcya854*, a deletion of the gene for adenylate cyclase[35], was introduced into recipient strains from Table 2 by Pl co-transduction with *ilv*::Tn*5*. The tested strains also were *ilv*::Tn*5* *Δgal165 thi*.

of CAP. The mutationally altered proteins preferentially recognize A·T base pairs at positions 7 and 16 of the symmetrical recognition site, rather than G·C base pairs as is the case with wild-type CAP. The simplest explanation of these results is that amino acid 181, wild-type or mutant, is the side chain of CAP that makes direct contact with base pairs 7 and 16 in the recognition site. By this hypothesis, glutamic acid 181 makes hydrogen bonds to G·C base pairs, whereas lysine leucine and valine at this position selectively hydrogen bond or otherwise interact with A·T base pairs.

In principle, it is possible that the mutations instead could alter DNA sequence recognition through an indirect, conformationally transmitted effect. However, based on several lines of evidence, we consider this alternative hypothesis unlikely.

(1) All three *crp′* mutations affect the same residue of CAP (amino acid 181). This result implies that there is a limited number—possibly only one—of targets at which amino acid substitutions can confer this phenotype. It is difficult to reconcile this result with possible alterations in specificity due to conformational effects, particularly long-range effects, which one would expect on structural grounds to have multiple targets.

(2) In the crystallographic structure of CAP, the side chain of glutamic acid 181 is completely exposed to solvent (ref. 17 and T. Steitz and I. Weber, personal communication). Glutamic acid 181 is located in an α-helix that protrudes from the surface of the protein, and it interacts neither with neighbouring amino acid side chains nor with other parts of the peptide backbone. Model building suggests that the three mutant side chains would similarly be fully exposed. The absence of interactions between amino acid 181 and other CAP residues argues that the mutant side chains would not perturb either local or global CAP conformation (see refs 28, 29).

(3) Glutamic acid 181 in wild-type CAP is in an α-helix[17] (helix F; Fig. 4). By the assignments of Chou and Fasman[30], the mutant side chains lysine, leucine and valine exhibit a probability comparable with that of glutamic acid to maintain α-helical conformation. Thus, the identified mutations are unlikely to alter CAP conformation through peptide backbone effects. (Examples of amino acids that would not fulfil this criterion are proline and glycine.)

Therefore, we propose that the *crp′* mutations alter sequence specificity by substituting the amino acid of CAP that makes direct contact with base pairs 7 and 16 of the DNA site. This conclusion is consistent with previous model building[16,18] and biochemical[27] analyses (see preceding section) which indicate that amino acid 181 is in the region of CAP expected to make contacts with DNA. The implications of our results for the molecular basis of CAP–DNA recognition will be discussed in detail elsewhere[9].

Conclusion

We have devised a simple genetic approach that enables us to identify amino acids of CAP which are directly involved in making sequence-specific contacts with DNA. The advantage of this experiment is that it not only identifies these amino acids, but also correlates them to the specific base pairs within the recognition site with which they make contact.

The genetic techniques described here could be applied with only minor modifications to a variety of other prokaryotic or eukaryotic DNA-binding proteins. In fact, Youderian and co-workers have used a closely analogous approach to isolate a mutant of P22 Mnt protein with altered DNA-binding specificity[31].

We acknowledge S. Adhya for the gift of λY1079 before its publication. We thank M. Ptashne and his co-workers for critical discussion and encouragement, I. Weber and T. Steitz for discussion, unpublished data and comments on the manuscript, Ms. A. McIntosh for typing, and G. Cohen and A. Ullmann for their constant interest in this research. Molecular hydrogen jets from the Orion nebula

The environs of interstellar space in which star formation takes place involve high-velocity gas flows. Channelled by embryonic dust toroids, these gas flows culminate in energy-losing shock processes at the interface with the ambient interstellar cloud. The excitation of molecular hydrogen transitions in this gas provides one means of observing these shocked regions and their relation to the well-known indicators of star formation such as the Herbig Haro objects and T Tauri stars. In an attempt to understand the relationship of the recently discovered complex of Herbig Haro objects in Orion[1] to the IR sources in this region, we have carried out a survey of the molecular hydrogen S(1) line distribution. These observations have led to the discovery of a previously unsuspected structure of finger-like filaments of H_2 emission extending radially outwards from a common centre at IRC9.

This survey was carried out using the Anglo-Australian Telescope in conjunction with the IR photometer and spectrometer. Areas of the sky were observed by scanning the telescope in a raster pattern, using the imaging mode with an aperture of 2 arc s diameter and a scan interval (1 pixel) of 1 arc s. The circular variable filter (CVF, resolution 100) was set to the wavelength of the peak of the S(1) transition at 2.12 μm. A total integration time per pixel of 0.2 s produced a limiting detectable flux (3σ level) at S(1) of $\sim 10^{-13}$ erg cm^{-2} s^{-1}. The images obtained in this manner indicate the distribution of the net emission at this wavelength arising from both the continuum and S(1) radiation. A subsequent image at a continuum wavelength (2.09 μm), or at worst a series of spectra taken at strategic positions in the object, can then be used to derive the molcular hydrogen distribution.

Two 100-arc s square images of Orion were obtained, centred on the BN object. One of these was obtained in the S(1) line wavelength and the other was taken to provide a map of the continuum emission. Further images were obtained at 2.12 μm at locations to the north of the BN object (one 100 × 100 arc s centred 90″N, 15″W and a second 64 × 64 arc s centred 72″N, 68″E). Time limitations prevented us from obtaining a continuum map at these new locations; however, we were able to obtain several spectra in the brighter H_2 knots to establish the local S(1) line-to-continuum intensity ratio at these points and also a broad K-band image of the 64-arc s square region. The seeing at the time of these observations was ~1 arc s and our observations resulted in the highest spatial resolution map of H_2 yet obtained for this complex.

The combined images at 2.12 μm taken from the computer graphics display are shown in Fig. 1. Regions of significant continuum emission (2.09 μm) in the southern section are shown. The localized emission sources at 2.12 μm which do not appear on the continuum map are emphasized. In addition, the locations of the known Herbig Haros are indicated. Finally, the positions at which spectra in the 2-μm band were obtained are also shown. The spectra themselves are given in Fig. 2, fluxed with respect to the star BS2007 which was used as a standard[2].

Two immediately striking features are evident from Fig. 1: first, the large spatial extent over which a complex distribution

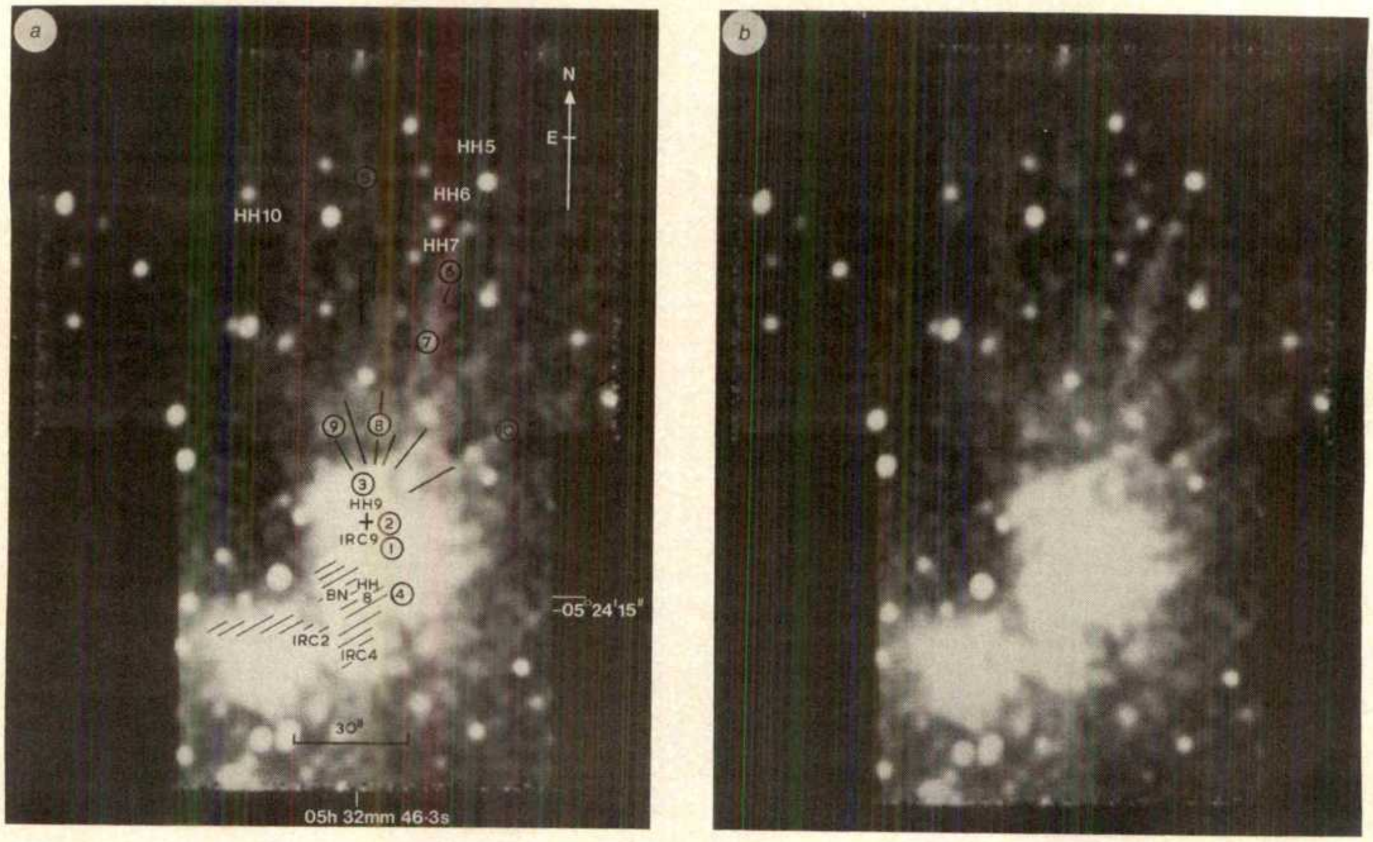

Fig. 1 Photographs of the computer graphics display of a montage of the three images of the molecular hydrogen distribution. The image has been smoothed over five pixels and the display levels have been set to emphasize the low-intensity jet region of the final picture. *a* is annotated, while *b* is untouched to avoid biasing the apparent orientation of the jets. Scale bar, 30 arc s. Regions of significant extended continuum emission are shown hatched. The locations of the Herbig Haro objects HH5, 6, 7, 8, 9 and 10 in M42 are shown along with the sources IRC1, 4 and 9. The positions at which the 2–2.5 μm spectra were obtained are shown by a circled number.

appears at 2.12 μm, which is not, however, evident in the continuum map and second, and more importantly, the appearance of the long fingerlike structures extending radially outwards from the main body of molecular hydrogen.

Although an understanding of the detailed nature of the overall H_2 distribution is of considerable importance to our knowledge of this region, below we only concentrate on the previously unknown, and unsuspected, jet-like structures. That at least a significant fraction of the total emission in these jets arises from the S(1) transition is evident from the spectra of Fig. 2.

While the Orion region is experiencing a bipolar outflow of material[3–7], it has previously been assumed that the envelope of this flow is in the form of a smooth, continuous, bubble. In view of our observations this can only be a broad generalization of the real structure, and there are several explanations for the jet-like structures of Fig. 1. We suggest four below:

(1) The formation of the expanding bipolar bubble by the stellar winds from the central object has resulted in considerable structure on the inner face. Because of the internal dynamics, such structure can take the form of channels initiated by local density fluctuations in the cloud. The outflowing hot gas then illuminates this structure as it strikes the interface. Such a model would require the outer limits of the bipolar flow to extend beyond the limits thought (K. Taylor and D. Axon) to include the Herbig Haro objects M42 HH5, 6, 7 and M42 HH10[1].

(2) The fingers are hot, dense gas breaking through weaker regions of the outer cool material and extending into jets as it penetrates the ambient cloud.

(3) In agreement with the 'interstellar bullet' model of Herbig Haro formation[8–10], small dense clumps of the interstellar medium have been accelerated by the wind from the central star and are now leaving trails of shock-excited molecular hydrogen in their wake.

(4) The structures represent local enhancements in the dust density and the molecular hydrogen is seen by reflection of the emission from the core of the molecular cloud.

In each case, the emission is due to shock excitation rather than UV photoexcitation of the molecular hydrogen, consistent with the observed ratios of the $v = 1$ and $v = 2$ S(1) lines[5].

One feature then remains to be considered. If the lines of the jets of Fig. 1 are extended backwards into the molecular cloud they appear to intersect at IRC9 rather than at IRC2. This is significant, as IRC2 is believed to lie at, or near to, the origin of the bipolar outflow[6]. The possible role of IRC9 in this phenomenon requires further study, a conclusion supported independently by the work of Beck[11].

Furthermore, high-velocity resolution spectra are now needed to allow us to distinguish between the models proposed for those jets, and corresponding searches for similar structures are needed to establish whether this is a general feature of bipolar outflows in star forming regions. Similarly, observations of other molecules normally associated with shocked molecular hydrogen could reveal the ambient conditions of density and temperature at the jets. Finally, a relation between the jets and the Herbig Haro objects M42 HH5, 6 and 7 seems likely and could be verified by measurement of the Doppler-shifted velocities of the S(1) and nebular emission lines.

We thank the Australian Time Allocation Committee for awarding time on the telescope and members of the observatory for their valuable assistance. We also thank David Allen for encouragment, and a referee for drawing our attention to the preprint by Beck (1984) dealing with the object IRC9.

Received 18 April; accepted 3 July 1984.

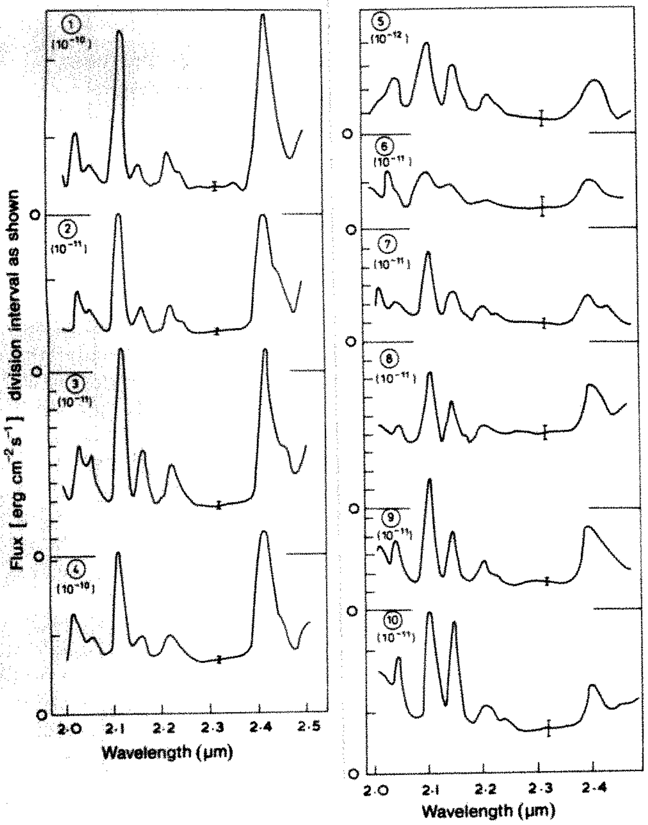

Fig. 2 The 2–2.5 μm spectra taken at the various points shown in Fig. 1. Spectra 1–4 were taken within the extended molecular cloud while spectra 5–10 were observed in the vicinity of the molecular hydrogen jets. The apparently anomalous Q branch to S(1) line ratio almost certainly arises because of rapid fluctuations in the atmospheric absorption which lead to incomplete cancellation when ratioing to the standard star. The 3σ levels are indicated in the continuum region of each curve.

Observations from IRAS (the Infrared Astronomical Satellite) have shown that the peculiar galaxy Arp220 (=IC4553) has extreme IR properties[1]. Its IR luminosity is 100 times greater than normal spirals and nearly equals that of the most luminous Seyfert known, Mkn231. Its optical appearance suggests that it is either

a recent merger or that it has a prominent central dust lane. Soifer *et al.*[1] have discussed whether a starburst or a Seyfert nucleus can better explain their observations. We report here 20-, 350- and 760-μm observations which constrain the mass and size of the emitting region and compare Arp220 with the archetypal starburst galaxy M82.

The submillimetre observations were made with the United Kingdom Infrared Telescope on 1 May, and the 20-μm observations on 3 June 1984. At 350 μm we find 8.7 ± 1.2 Jy in a 55 arc s beam and at 760 μm a 3 σ upper limit of 3.2 Jy in a 58-arc s beam. The total uncertainty in the 350-μm flux density, including the calibration as well as statistical uncertainties, is 1.9 Jy. The beam sizes used should contain all the submillimetre flux from Arp220 whose size was determined by IRAS as < 25 arc s (ref. 1). At 20 μm we find 1.7 ± 0.2 Jy in a 4-arc s beam, and no significant flux in adjacent 4-arc s beams.

Figure 1 shows the measured submillimetre and IRAS[1] flux densities fitted, except at 12 μm, with a thermal dust spectrum; the absorption coefficient of the dust was taken to vary as frequency squared, which is appropriate for those wavelengths beyond which the source is found to be optically thin[2]. (We did not fit the IRAS 12-μm point because its colour correction[3] is strongly temperature dependent at these low temperatures.) With 1 d.f. the value of χ^2 was 1. The fit yields a value of 61 K for the temperature parameter and a solid angle filled by the source of 3.8×10^{-11} sr. The optical depth is 1 at 180 μm and 0.26 at 350 μm. The IR luminosity is $2 \times 10^{12} L_\odot$ assuming a distance of 90 Mpc (ref. 1).

Assuming that the properties of dust, and the gas-to-dust ratio, are the same in Arp220 as summarized by Hildebrand for the Galaxy[2], our model fit determines the mass of gas in the IR emitting region to be $7 \times 10^9 M_\odot$. Bearing in mind the uncertainties in the properties of the dust, we believe this estimate to be accurate to within a factor of two. Presumably most of this gas is in molecular form.

A lower limit to the size of the emitting region is set by assuming that the observed solid angle is that subtended by a single spherical lump of material; this gives a diameter of 1.4 arc s. Our 20-μm flux density measured in a 4-arc s beam is consistent with extrapolation of our fit to the IRAS 25-μm flux density measured with a much larger beam, and our 20-μm mapping shows no evidence for significant 20-μm flux outside one 4-arc s beam diameter. We conclude, therefore, that the emitting region is between 0.6 and 1.7 kpc in diameter, giving a molecular gas density of between 1×10^2 and 2×10^3 nucleons cm^{-1}.

At the density and temperature deduced for the cloud we would expect star formation to take place. The suggested presence of many OH masers[4] is consistent with this idea. It is interesting to compare Arp220 with the starburst galaxy M82 (ref. 5), whose luminosity is $3 \times 10^{10} L_\odot$ and whose spectrum[6] is similar to many H II region/molecular cloud complexes in our Galaxy. The spectra of the two galaxies are very similar at long wavelengths but at shorter wavelengths the much greater optical depth of A220 is apparent (Fig. 1). The luminosity per nucleon for Arp220 of 9×10^{-29} W per nucleon is similar to the value of 7×10^{-29} W per nucleon in M82 (ref. 7). The ratio of the 6-cm radio flux density (which is a measure of supernova formation and Lyman continuum photon production rates) to the 100-μm flux density is also similar for the two galaxies[1]. It is, therefore, tempting to interpret the IR luminosity of Arp220 as arising from a starburst involving the order of 100 times as much material as that in M82. The equally high IR luminosity of the galaxy NGC6240 has been interpreted as an interaction-induced starburst[8].

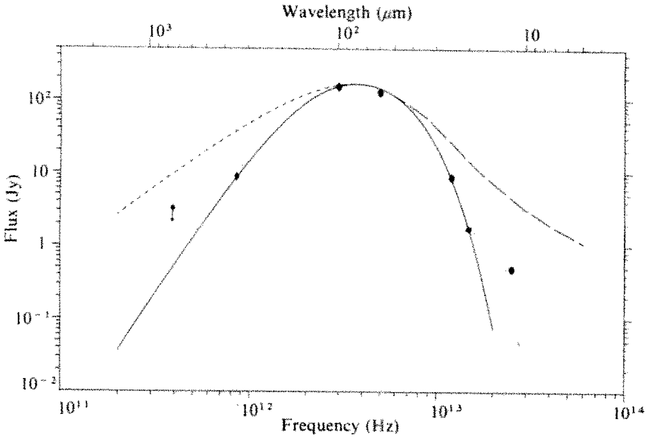

Fig. 1 The IR spectrum of Arp220. Data from: ◆, this paper; ● IRAS flux densities. Solid curve, model fit (see text). Short dashed curve, extrapolation of a 61-K black body. Long dashed curve, short-wavelength spectrum of M82 normalized to 60-μm flux denisty of Arp220.

We thank the SERC's PATT for the allocation of observing time. G.G. and L.M.J.B. acknowledge research studentships and M.J.G. a research assistantship from SERC.

Accurate atomic positions from electron microscopy

Sven Hovmöller*, Agneta Sjögren*, George Farrants*, Margareta Sundberg† & Bengt-Olov Marinder†

* Department of Structural Chemistry, and † Department of Inorganic Chemistry, Arrhenius Laboratory, University of Stockholm, S-106 91 Stockholm, Sweden

Modern electron microscopes have resolutions in the range 1.8–2.4 Å which is, in principle, sufficient for structure determination at atomic resolution. High-resolution electron microscopy (HREM) has been widely used for studies of inorganic materials[1], and computerized image processing of electron micrographs has been used for structure determinations of biological macromolecules[2,3]. Klug[4] suggested that image processing could also be applied to electron micrographs of inorganic crystals. By combining the two powerful methods, HREM and computerized image processing, we have determined atomic coordinates (in projection) of metal atoms in a thin inorganic crystal, to an accuracy of 0.1 Å. This high accuracy is mainly due to the noise reduction achieved through averaging over many identical unit cells.

A sample with composition $K_{8-x}Nb_{16-x}W_{12+x}O_{80}$ (where $x \sim 1$) was ground to a fine powder and dispersed in *n*-butanol. A drop of this suspension was collected on a holey carbon film supported by a copper grid and examined in a JEOL JEM 200CX/THG 2 electron microscope equipped with a top entry ultrahigh resolution goniometer and operated at 200 kV. HREM[1] was used to examine a crystal with a very thin edge. The crystal was oriented so that the short unit cell axis was parallel to the electron beam by using the criterion that the electron diffraction pattern should be symmetrical (Fig. 1*a*). In this way, the two longer unit cell axes were both in the plane of projection. Several HREM images were recorded at different defocus values.

The electron micrographs were analysed by eye and in an optical diffractometer equipped with a laser. The diffraction Hpattern of the micrograph is seen in the back focal plane of the objective lens of an optical diffractometer and can be used

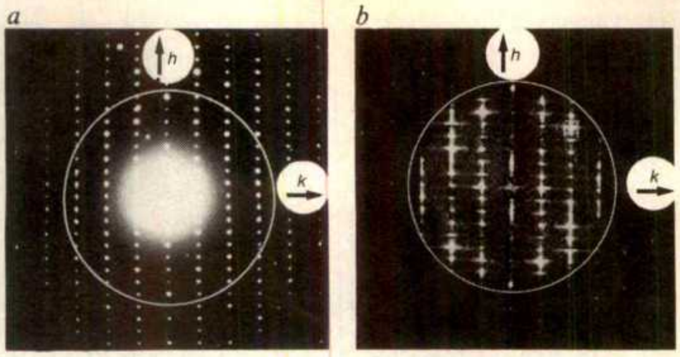

Fig. 1 Diffraction patterns from $K_{8-x}Nb_{16-x}W_{12+x}O_{80}$. Reflections with k odd are systematically absent. The fine rings correspond to 2.4-Å resolution. *a*, Electron diffraction of the microcrystal, a small part of which is shown in Fig. 2. *b*, Amplitude part of the diffraction pattern calculated by computer as the Fourier transform of the digitized electron micrograph. The picture has been photographed from the computer graphics screen. The contrast transfer function is visualized in the background noise. The boxed area is shown in greater detail in Fig. 3*a*.

to evaluate quantitatively the quality of the micrograph. The level of defocus can be determined by the positions of the nodes of the contrast transfer function, which are seen as dark rings in the pattern[5]. The shape of the rings shows the presence or absence of astigmatism in the picture—a non-astigmatic picture will have circular rings, an astigmatic picture will have elliptical rings. The micrographs taken at different defocus values were examined in the optical diffractometer, and one which had been taken very close to Scherzer focus was selected for further analysis. In this micrograph the first node occurred at 2.4 Å resolution.

The contrast in a HREM image, taken at optimum defocus (Scherzer focus), of a properly oriented crystal thin enough to approximate to a phase object, may be directly interpreted in terms of the local projected structure of the crystal[6]. In these conditions, the black features in the micrograph (Fig. 2) represent scattering atoms. This has been verified by computed crystal structure images of the model in Fig. 4*b*. Good agreement was obtained between observed (Fig. 2) and calculated images at a defocus of −633 Å (Scherzer focus) and a crystal thickness of $5\times3.9\sim20$ Å (ref. 7).

The thin area of the crystal showed both a constant local average optical density and a constant optical diffraction pattern, indicating that variations in thickness, structure and orientation were very small in the processed region. These conditions are necessary for applying our method. An area corresponding to 90 unit cells was digitized using a Joyce-Loebl Microdensitometer 6. A raster size of 50×50 μm was used and 256×256 points were scanned. At a magnification of 690,000 times, this corresponds to a sampling interval of 0.72×0.72 Å^2. Such sampling preserves the details of the structure to at least 2.0 Å resolution. The information in the electron micrograph, present as a variation in optical density, was transferred in digital form to a VAX 11/750 computer.

The Fourier transform of the digitized image was calculated. The digital transform is closely related to the analogue optical diffraction pattern. If the optical diffraction pattern is recorded on photographic film, the phase information is lost, whereas the calculated diffraction pattern contains both the amplitude and the phase information of each diffraction point. The amplitude part of the complex numbers of the Fourier transform was displayed on a Digital VS11 raster graphics system (Fig. 1*b*), and the lattice indexed with the aid of a cursor. The diffraction spots were very sharp, and the phases constant over the whole spot (Fig. 3). Lattice parameters were refined from accurate positions of 12 strong diffraction spots. The cell parameters obtained were $a=22.1+/-0.3$ Å, $b=17.8+/-0.3$ Å, $\gamma=89.9+/-0.4°$. The amplitudes and phases for all 47 reflections in the unique half of the diffraction pattern within a resolution of 2.4 Å were obtained automatically by computer. Amplitudes were calculated by integrating over the 3×3 points closest to the predicted position of the lattice point in the Fourier transform followed by subtraction of the local background, and the phases were taken as the phase value of that point in the Fourier transform which was closest to the predicted lattice point. The accuracy of this method was evaluated by comparing the amplitudes and phases from two scans of the same area of the micrograph, one scanned in a direction parallel to the crystal axes, and the other along the diagonal of the unit cell. The two sets of amplitudes and phases were virtually identical.

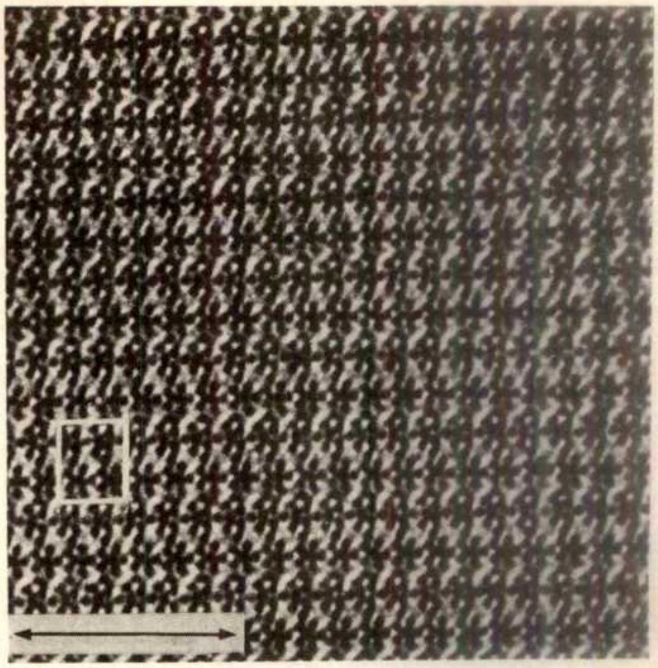

Fig. 2 Electron micrograph of a thin crystal of $K_{8-x}Nb_{16-x}W_{12+x}O_{80}$, projected over a hole in the carbon film. The defocus was about −630 Å. The area shown is the one used for computerized image processing. Atoms appear dark in the picture, and the pentagonal arrangements are clearly visible. One unit cell is indicated. Scale bar, 50 Å. Magnification, $\times4.6\times10^6$.

For the method to be valid, the specimen in the microscope should behave as a weak phase object—a first-order (kinematical) approximation must be sufficiently accurate to describe the image formation process, and the second-order (dynamical) effects should be small. When this condition is satisfied the product of each Fourier component with the zero-order term ($F(000)$) will be much greater than the products of the Fourier terms with each other.

The validity of this assumption was examined using the method described by Erickson and Klug[8]. The difference

Table 1 Atomic coordinates for the heavy metal atoms (Me) in $K_{8-x}Nb_{16-x}W_{12+x}O_{80}$ as determined by electron microscopy and image processing, and in $Na_7Nb_{15}W_{13}O_{80}$ as determined by X-ray diffraction[10]

	Fractional atomic coordinates					
	Electron microscopy		X-ray diffraction		Difference EM/X-ray	
Atom	x/a	y/b	x/a	y/b	x/a	y/b

Fig. 3 Extract from the Fourier transform around one diffraction point ($h=5$, $k=4$). This area corresponds to the boxed area in Fig. 1*b*. *a*, Amplitude part, scaled such that the $F(000)$ term has a magnitude of 20,000. *b*, Phase part relative to an arbitrary phase origin, given as (phase in degrees)/10. The predicted position of the lattice point ($X=39.77$, $Y=-43.41$) falls between four sampling points of the Fourier transform. The amplitude is spread over these four sample points, and the phase is constant over the whole diffraction point. The theoretical shape of the diffraction point is a $\sin(x)/x$ function for a perfect single crystal. Deviations from this shape show lack of order in the crystal lattice. It can be seen that the $\sin(x)/x$ behaviour is accurately followed, with the phase changing by 180° in a series of rings around the central maximum. The period of x is two transform units.

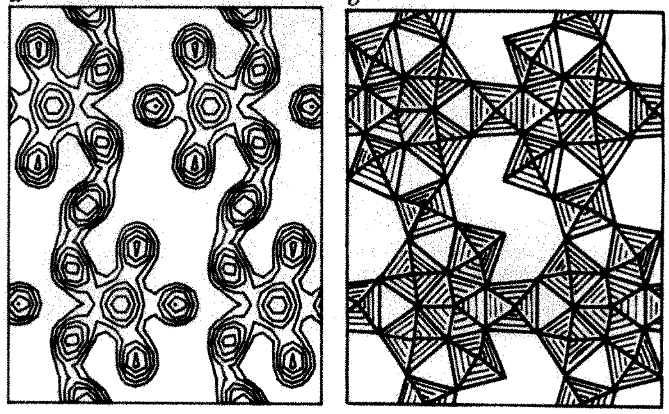

Fig. 4 *a*, Contour map of $K_{8-x}Nb_{16-x}W_{12+x}O_{80}$ after averaging over the 90 unit cells digitized from the electron micrograph, and over the four asymmetric units in the unit cell. One unit cell is shown. The density map was contoured at nine equidistant levels. The five contour levels corresponding to the highest density are shown. The MeO_7 bipyramids and MeO_6 octahedra are seen as circular features of high density. Scale 5 mm per Å. *b*, Model of $Na_7Nb_{15}W_{13}O_{80}$ determined from X-ray diffraction. The MeO_7 bipyramids and MeO_6 octahedra are drawn such that the heavy metal atoms are at the centre of each bipyramid and octahedron. The sodium atoms are not shown. Scale 5 mm per Å.

between the average optical density of the thin area used for reconstruction and the average optical density of the background was used to place the magnitudes of the Fourier components on a scale relative to an $F(000)$ term of 1.00. The strongest reflection is then the (3, −4) with a magnitude of 0.084. The strongest second-order diffraction effect would then be the interaction of this reflection (and equivalent reflections), with a magnitude of $0.084\times0.084=0.0071$. This value is small when one takes into account the fact that 28 out of the 47 reflections had magnitudes greater than 0.01. Thus, any second-order interaction will be small compared with the first-order interactions, and the weak phase object approximation is valid.

The symmetry of the crystal is orthorhombic, space group *Pmab* (no. 57 in ref. 9), as determined from electron diffraction patterns of the three orthogonal views (h, k, 0), (h, 0, l), (0, k, l). Very weak reflections indicating a doubling of the c-axis were observed, but since the processed image represented the projected atomic structure along the c axis, these reflections are unobserved and have no effect on the image processing. Thus, we use here the space group appropriate for the basic structure. In this space group, there is a two-fold axis parallel to the c-axis, a mirror plane perpendicular to a, and 2_1 screw axes parallel to the a and b axes. The effects of these symmetry elements on the amplitudes and phases of the diffraction points are the following: the amplitudes show *mm* symmetry, that is, $|F(hk0)|=|F(\bar{h}k0)|=|F(h\bar{k}0)|=|F(\bar{h}\bar{k}0)|$, all phases are centric with phases of 0° or 180°, $(hk0)$-reflections with k odd and $(h00)$-reflections with h odd are systematically absent, and the phases of the reflections $(hk0)$ and $(\bar{h}k0)$ are equal if h is even, and differ by 180° if h is odd.

The presence of a two-fold axis along c was investigated quantitatively by examining the phase residual between the observed phases and centric values. The phase residual, R, was calculated as:

$$R=\frac{\sum_i w_i\phi_i \ (\mathrm{mod}\ 180)}{\sum_i w_i}$$

where, for i reflections, w_i is a weighting factor (here set to be equal to the amplitude of the reflection), and ϕ_i is the observed phase of the reflection. When the origin of the unit cell is positioned exactly on a two-fold axis, all the reflections have phases of 0° or 180°. The arbitrary origin which comes from the starting position of the densitometer is unlikely to correspond to this two-fold axis, and the observed phases will then take on arbitrary values between 0° and 360°. A computer program moves the position of the origin stepwise along both a and b to a total of 120 × 120 evenly spaced points within the unit cell. For each of these positions, the deviation from the nearest of 0° or 180° is calculated for all reflections. The phase residual is printed out in the form of a map, and the position of the lowest residual is found. For this crystal the lowest phase residual was 17°, which should be compared with the average residual of 45° for positions other than the two-fold axes. The origin of the unit cell was shifted to coincide with this two-fold axis, and the phases of all reflections were recalculated relative to this origin, by applying proper phase shifts to the reflections.

Before calculating the final map, the space group symmetry, determined as outlined above, was imposed. Imperfections in the imaging process, noise in the electron micrograph and deviations from the exact crystallographic orientation with the electron beam going along c, cause the experimentally-determined amplitudes and phases to deviate from the symmetry-constrained values. The phases of all reflections with experimentally-determined phases in the range −90° to +90° were set to 0°; otherwise the phases were set to 180°. Approximate *mm* symmetry was made exact by averaging the amplitudes of the two symmetry related observations of a reflection ($h, k, 0$) and ($h, \bar{k}, 0$). The final map of the unit cell was obtained by calculating the inverse Fourier transform of the symmetry averaged centrosymmetric set of structure factors.

The map was calculated on a grid of 32×32 points along the unit cell edge and contoured at nine equidistant levels. The five contour levels corresponding to the highest scattering potential are shown in Fig. 4*a*. All 28 heavy metal atoms in the unit cell are clearly visible as peaks of density arranged in four pentagons. The symmetry of the crystal is such that there are only five unique heavy metal positions in the unit cell. The coordinates of the heavy metal atoms were determined from the density map. To check the accuracy of the structure determination by image processing, these coordinates were then compared with those found independently by X-ray crystallographic methods on the isostructural sodium compound[10] (Table 1). The structure is built up of pentagonal MeO_7-bipyramids and MeO_6-octahedra (Me = Nb or W) as shown in Fig. 4*b*. Each bipyramid is linked by equatorial edge-sharing to five octahedra forming a star-shaped cluster of polyhedra. Along the *a* axis the units are linked by an MeO_6-octahedron through corner sharing. Four of the 10 atomic coordinates are fixed by symmetry to be 0 or 1/4. All the other six positional parameters agree to within < 1/100 of a unit cell. The average difference in positions found by the two methods was 0.10 Å, with the largest difference being 0.14 Å.

The X-ray structure determination of the isostructural sodium compound showed that the niobium and tungsten atoms were distributed over all five positions, with different site occupancies. In the map reconstructed by image processing, all peaks have the same height to within 10%, but the significance of these differences has not been examined.

We have demonstrated, therefore, that, for a thin and unbent crystal, it is possible to determine the positions of metal atoms in the crystal lattice with an accuracy of 0.1 Å, by combining high-resolution electron microscopy and computerized image processing, without using any previous information about the crystal structure.

This investigation was carried out with financial help from the Swedish National Science Research Council (NFR). A grant from the Knut and Alice Wallenberg Foundation for the electron microscope is gratefully acknowledged.

Bouguer images of the North American craton and its structural evolution

R. E. Arvidson, D. Bindschadler*, S. Bowring, M. Eddy, E. Guinness & C. Leff

McDonnell Center for the Space Sciences, Department of Earth and Planetary Sciences, Washington University, St Louis, Missouri 63130, USA

Processing of existing gravity and aeromagnetic data with modern methods is providing new insights into crustal and mantle structures for large parts of the United States and Canada[1–3]. More than three-quarters of a million ground station readings of gravity are now available for this region. These data offer a wealth of information on crustal and mantle structures when reduced and displayed as Bouguer anomalies, where lateral variations are controlled by the size, shape and densities of underlying materials. We have used digital image processing techniques to generate Bouguer images that display more of the granularity inherent in the data as compared with existing contour maps. A dominant NW–SE linear trend of highs and lows can be seen extending from South Dakota, through Nebraska, and into Missouri (Fig. 2). The structural trend cuts across the major Precambrian boundary in Missouri, separating younger granites and rhyolites from older sheared granites and gneisses. This trend is probably related to features created during an early and perhaps initial episode of crustal assembly by collisional processes. The younger granitic materials are probably a thin cover over an older crust.

Our processing technique, which is based on local arithmetic averages of Bouguer values, was chosen specifically to preserve local details[4], thus enhancing short wavelength anomalies of probable crustal origin. The data were reduced to Bouguer anomalies using the 1967 International Gravity Formula and a slab density of 2.67 $g\,cm^{-3}$. The interpolated results are displayed in a shaded relief form in Fig. 2 for an area centred on the midcontinent. We concentrate on delineating and interpreting NW–SE trending features in the midcontinent, covering the Dakotas, Nebraska, and Missouri. This area is one where gravity and magnetic data can provide considerable information on crustal structure as much of the region is covered by Phanerozoic sedimentary rocks.

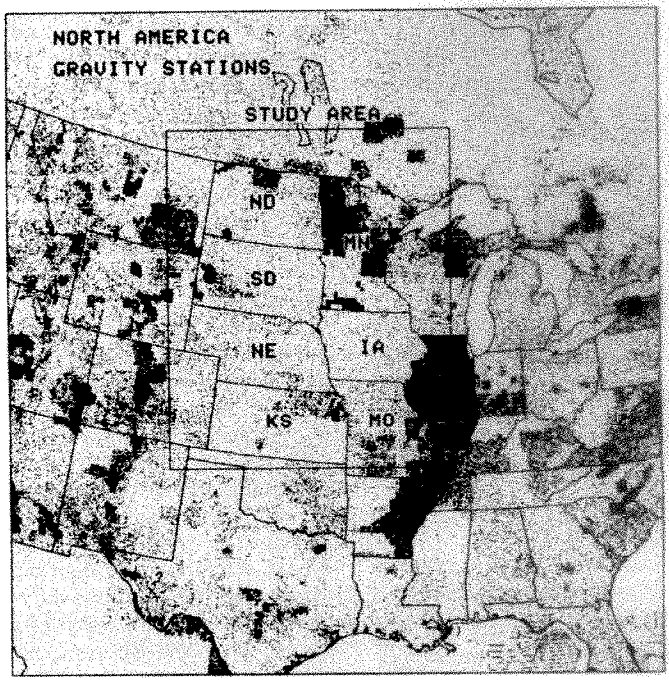

Fig. 1 Gravity station locations are shown as dots in this Lambert equal area projection of part of the United States and southern Canada. Bouguer anomalies for the station locations were utilized with the interpolation technique discussed in the text to generate the Bouguer images shown as the shaded relief map in Fig. 2. ND, North Dakota; SD, South Dakota; NE, Nebraska; KS, Kansas; MN, Minnesota; IA, Iowa; MO, Missouri.

Figure 3 is a sketch map compiled from the Bouguer images and from available geological data. This area includes the Superior Province (2,500–2,700 Myr (ref. 5)), the Churchill

---

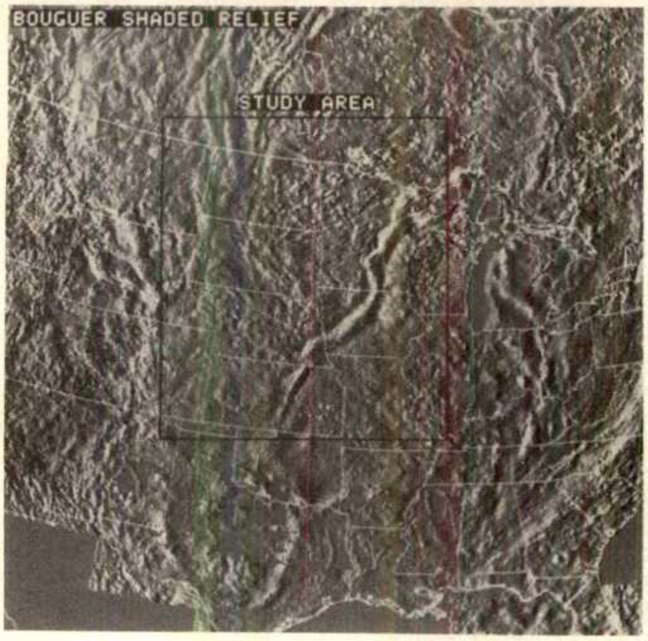

Fig. 2 Shaded relief map of Bouguer anomalies, with simulated sun placed at 20° above the western horizon. The flat, grey areas in the southern United States are places where the areal density of data was too low to allow meaningful interpolations.

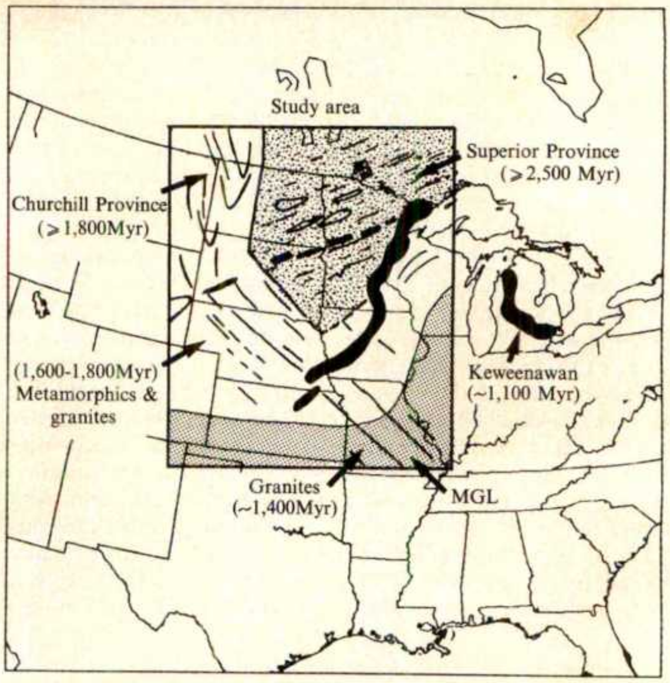

Fig. 3 Interpretation map of the study area. The Great Lakes Tectonic Zone is shown as a series of thick lines running NE–SW in Minnesota. Also shown is the projection of the tectonic zone into Wyoming. The continuity in trend and form of NW–SE structures to the south of the linear zone suggests a common origin. The deep-seated Missouri Gravity Low (MGL) has apparently been covered with a veneer of younger granites in southern Missouri.

Province (1,800–1,900 Myr, with residual Superior ages[5]), and areas to the south. We have included part of Canada because large parts of the Superior and Churchill Provinces are exposed, thereby allowing the Bouguer trends to be interpreted in concert with extensive geological data. Trends within the Superior Province are largely NE–SW, reflecting the presence of belts of mafic metavolcanic rocks[6]. The western boundary between the Superior Province and the younger Churchill Province shows up clearly in the images, partly because the structural fabric has very different wavelengths and trends in the two provinces. The Churchill Province exhibits structures that trend in N–NW directions. These structures consist of curvilinear belts of metamorphic and igneous rocks that are thought to have formed in a series of collisional events associated with convergent plate margins[7,8].

The Churchill trend appears to be truncated along a linear zone extending NE–SW from Minnesota, through South Dakota, and into Wyoming. This zone corresponds to the Great Lakes Tectonic Zone in Minnesota and to the Wyoming Shear Zone in Wyoming[9,10]. The structures to the south of the zone strike more towards the NW and have a finer texture than do the structures in the Churchill Province. Our presentations show that this NW–SE trending fabric extends from South Dakota to the southeastern section of Missouri. The NW–SE trending fabric extending into Missouri has clearly been cut by the younger ∼1,100 Myr basalts emplaced during the Keweenawan rifting event[11]. Within the zone of NW–SE trending fabric, the Precambrian terranes consist of igneous and metamorphic rocks that range in age from 1,600 to 1,700 Myr in South Dakota and Nebraska, to undeformed granitic rocks 1,300–1,400 Myr in age in southern Missouri[12]. As shown in Fig. 3, the northern boundary of the younger granitic rocks runs in an E–W to NE–SW direction, roughly perpendicular to the NW–SE trending fabric.

The dominant NW–SE trending feature in Missouri, the 'Missouri Gravity Low' (MGL)[13,14], is 700 km long, 120 km wide, and has a maximum amplitude of ∼−40 mGal. It is best modelled as a 4–6 km crustal excess at the Moho[15]. The gravity signature of the Missouri feature is similar to those for modern rift valleys. On the other hand, negative Bouguer rift signatures arise because of sediment fill or because of low-density magma ponded at the base of the crust[16]. Neither hypothesis seems valid for the Missouri feature, since: (1) no Precambrian sediments are associated with the gravity low, and (2) the last major magmatic activity was associated with mafic dykes and sills that are unconformably overlain by Cambrian sediments[15]. It is equally difficult to explain the Missouri feature as a shear zone, given the amplitude of the low[15]. The most plausible origin is one involving crustal thickening due to events associated with convergent plate margins[17]. In fact, the signature is not unlike the pattern found in selected regions within the Churchill and Superior Provinces[7,8].

The preservation of the deep-seated MGL beneath the granitic basement of southern Missouri is consistent with the younger granitic rocks being a veneer emplaced over an older igneous and metamorphic crust. Neodymium–samarium data imply that the Missouri granites and rhyolites formed by partial melting of crustal rocks that have a mantle separation age of ∼1,800–1,900 Myr (ref. 18). The mantle separation age is similar to the age of the hypothesized collisional events to the north that produced the Penokean, Trans-Hudson and Wopmay Orogens[5]. Given the cumulative evidence, it is not inconceivable that the NW–SE trends in South Dakota, Nebraska, and Missouri formed by collisional processes similar to those that occurred to the north, during approximately the same time period. We treat such a hypothesis as intriguing and one deserving further scrutiny and evaluation. If true, much of the original Proterozoic craton was assembled in a similar manner over a relatively brief interval.

Periodic gravity changes at Poás volcano, Costa Rica

H. Rymer & G. C. Brown

Department of Earth Sciences, The Open University, Walton Hall, Milton Keynes MK7 6AA, UK

The measurement of gravity over active volcanoes is usually aimed either at the development of sub-surface structural models[1–4] or the investigation of temporal changes in gravity associated with magma movements[5–13]. The positive gravity anomaly over Poás volcano, Costa Rica[4] indicates the presence of a cylindrical pipe of denser material extending to several kilometres depth. Although the volcano is active, this feature has remained apparently stable for at least the past four years. However, our programme of high-precision microgravity studies indicates changes with amplitudes of 120 μGal at the crater rim and 50 μGal on the flanks with a periodicty of ~30 days. These data are interpreted in terms of either relative movements of several metres between the magma body and the stable volcanic edifice or of cyclic density change related to the degree of vesiculation or crystallization of the magma: there is a possibility that these variations are tidally induced. Such studies may have wider relevance in analysing previously unrecognized components of microgravity change and in the monitoring of active volcanoes.

Theoretical considerations[8,14,15] may be used to describe mathematically the vertical and horizontal elastic deformation of the crust due to hydrostatic pressure changes associated with sub-volcanic magma movements. In gravitational terms, we may anticipate a cyclic sequence involving pre-eruptive inflation of a volcanic cone, associated with gravity decrease according to the free-air gradient, followed by post-eruptive deflation and gravity increase. Coupled microgravity–elevation studies related to eruptions at Kilauea volcano, Hawaii[7,8], at Pacaya volcano, Guatemala[9,10] and at the Icelandic rift near Krafla[11] record parts of this cycle and show that high precision measurements provide a powerful method for monitoring and locating active areas in a volcanic system. More significantly, in terms of our results on Poás, Eggers[10] has reported evidence for sub-surface magma density changes at Pacaya. In contrast, small changes of gravity and elevation at Etna[12,13] do not record a major inflation–deflation cycle but were related to magma movements through sub-terranean fissures. The gravity–elevation data for these volcanoes raise two interesting questions: (1) how typical are the large (hundreds of μGal) gravity changes associated with eruptions that have been observed at Kilauea, Pacaya and Krafla, and (2) to what extent are the smaller changes (tens of μGal) observed at Etna unambiguously related to magma movements?

Situated at 10°11′ N, 84°13′ W, Poás is the only active member of a NNW–SSE oriented line of dominantly pyroclastic calc-alkaline volcanic centres comprising the Cordillera Central of Costa Rica (see Fig. 1*a*). The volcano is apparently in a state of equilibrium where thermal gains and losses are balanced, yet magma must be present at a shallow depth. A full gravity and elevation survey at 45 stations covering the summit area in February 1979 revealed a closed positive residual Bouguer anomaly of 10 mGal amplitude[4] centred over the north-east corner of the crater (Fig. 1*c*). The anomalous area is approximately circular with the strongest gradients to the north and west but with lesser gradients where the gravity contours extend towards the old crater (south-east). The tight gravity contours define the cross-section of a shallow sub-surface cylindrical pipe extending to several kilometres depth and with a positive density contrast ($>250\ \mathrm{kg\ m^{-3}}$) compared to the ash–lava sequence of the Poás cone (surface density $\sim 2{,}100\ \mathrm{kg\ m^{-3}}$). It has been argued[16,17] that the cylindrical pipe is largely solidified lava but, in view of the geological evidence of shallow magma beneath the dome (Fig. 1*a*), we suggest that unvesiculated magma (density $\sim 2{,}500\text{–}2{,}600\ \mathrm{kg\ m^{-3}}$) may more plausibly occupy much of the cylinder.

Gravity measurements were repeated at selected stations on the crater rim and along a traverse 20 km south of the volcano (Fig. 1*b*) during February 1979, January 1981, at regular inter-

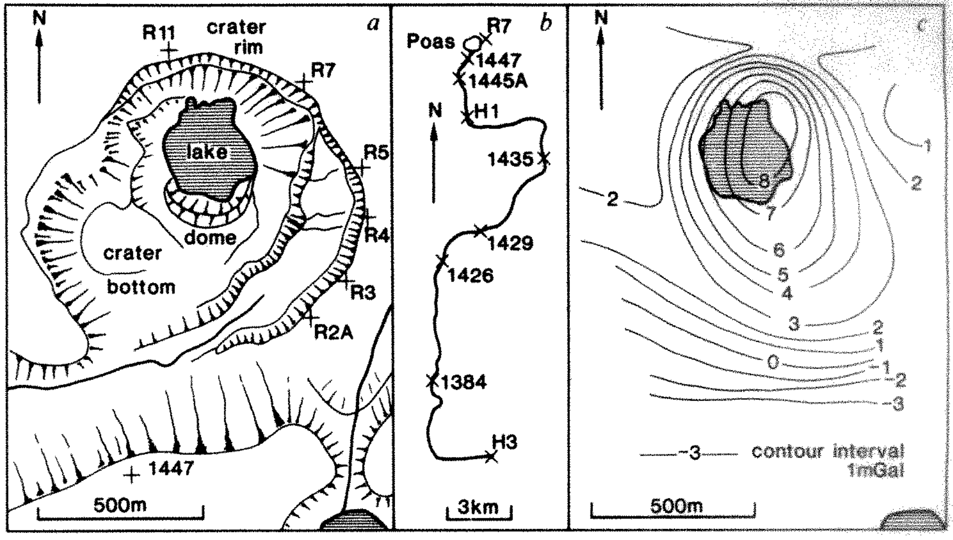

Fig. 1 *a*, Summit morphology of Poás volcano, Costa Rica. The area is characterized by the eroded remains of several calderas and includes an active crater with a steaming convecting lake (top centre) and a prehistoric crater with a cold water lake (bottom right). The active crater is three-sided and, with a floor at 2,320 m elevation, lies some 120 m below the surrounding plateau, or crater rim, where six gravity stations included in Tables 1 and 2 are marked. Activity is centred on an elongate pyroclastic dome (25 m high) with vigorous fumaroles, that stands on the south shore of the lake. The most recent large pyroclastic eruption was in 1953 when the crater floor dropped to its present level[21]; subsequent activity has involved geyser-like plumes of steam and mud, centred on the lake, with occasional ejection of lava blocks and juvenile material[16]. Since 1979, no major eruptions have been recorded although fumarole temperatures rose in 1980 and cracks in the dome have since glowed dull red after dark. *b*, Distribution of gravity stations along the road to the south of Poás used in the April–May 1983 survey. As the volcano approximates to a cone shape, basal diameter 25 km, rising to 1,200 m above the surrounding terrane, stations 1447 to 1435 are classified as flank stations, whereas 1429 to H3 are 'remote' stations. *c*, Residual gravity map of the Poás summit covering the same area and at the same scale as *a*.

Table 1 Gravity data in mGal, corrected for Earth tides and drift, and given with respect to 1445A

vals on 10 occasions throughout April–May 1983, and again in December 1983. All readings were corrected for theoretical Earth tides using the potential prediction programme of Broucke *et al.*[18] and a gravimetric factor for all constituents of 1.16. They were expressed first as gravity differences relative to a base station outside the volcano area, and gravity changes at individual stations were then calculated. The accuracy of the tidal prediction programme at this geographical location was tested by measuring the semidiurnal tide at one location for several days. Residual differences between observed and predicted gravity are a sum of any small programme errors combined with precision errors in meter reading, long-term drift and the effect of ocean loading tides. The standard error of these residual differences was 15 μGal, from which it follows that observed gravity changes exceeding 45 μGal have a 99.7% chance of being significant. A further source of error arising from disturbances due to movement of the meter on survey days is difficulty to assess, but from repeated readings at the base station, it appears to have been similar to the errors quoted above. Our total standard errors are likely to be <30 μGal (compare with the estimate of 35 μGal for Lacoste and Romberg meters[19]), although these exceed those reported in the high precision Etna work[12,13] partly because the meter used on Etna had an electrical readout, whereas G-513 is manual, and also because the observed accuracy of the tidal programme is included in our error estimate.

Gravity data measured in 1979, 1981, early 1983 and late 1983 at eight stations for which we have taken records on at least three occasions are summarized in Table 1. The maximum variation between any two sets of readings at a single station is 0.076 mGal at station R3. No systematic gravity changes occurred either with time or distance from the volcano over four years and it follows that no long-term changes in the Poás magma chamber can be resolved on this time scale. These data confirm the overall equilibrium state of the volcano and the small changes in Table 1 are attributed to the randomizing effect of reading errors (above)—only single readings are represented in the 1981 and December 1983 columns—and disturbance to the meter due to use elsewhere between visits to Poás. The more intensive higher precision studies at 11 stations during April–May 1983, however, have yielded some interesting results (Table 2). Assuming first that gravity is invariant with time, the r.m.s. deviations about the means for each station show a clear systematic decrease with distance from the crater—averages of 58, 48 and 33 μGal respectively for crater rim, flank and remote stations. These observations are statistically significant and imply that the invariant hypothesis is not valid, particularly for stations close to the volcano.

Because a degree of periodicity is observed in the data (Table 2), various simple sine waves were fitted to the data by choosing a period and calculating the amplitude and phase giving the minimum r.m.s. difference between observed and calculated values. From a range of periods, that for 30 days gave the optimum fit for all seven rim and flank stations (Table 2), the r.m.s. differences being distinctly less than for the straight line of the invariant hypothesis. We suggest, therefore, that an anomalous response with an ~30-day period is being recorded (Fig. 2). The effect is larger (~120 ± 60 μGal) at the crater rim stations than at flank stations (~50 ± 25 μGal). If these gravity changes were wholly attributed to elevation changes, then given a Bouguer-corrected free air gradient of 0.2 mGal m^{-1}, rim and flank stations would be rising and falling over 60 and 25 cm respectively during the 43 days of observation. Local tiltmeter data however, constrains elevation changes at rim stations to a few centimetres.

Having excluded elevation changes as the major source of

Table 2 Tidally corrected gravity data (in μGal) relative to values measured on 13 April 1983 which, therefore, are zero for every station

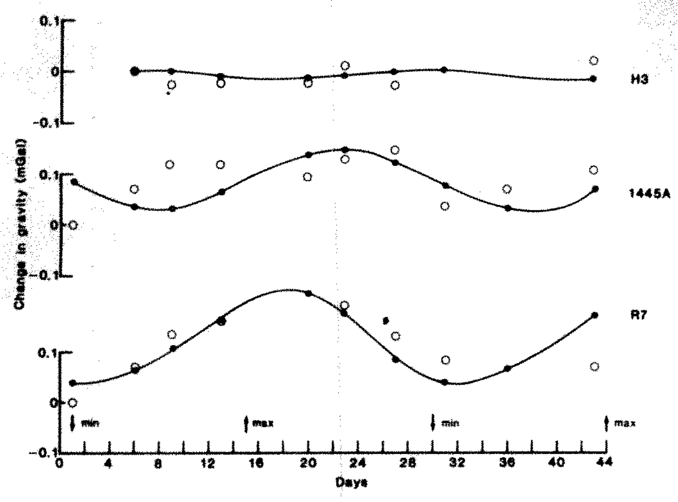

Fig. 2 Observed gravity changes with time at three selected stations (one for each group in Table 2); open circles, observed points; curves with solid circles, the calculated best-fit sine waves (unconstrained amplitude and phase) with a 30-day period. Note that the arrows indicate the maximum and minimum points on the predicted lunar synodic-tide (period 29.53 days) and that these are broadly in phase with the observations at R7. Whether this correlation between gravity change and the synodic tide is purely coincidental remains to be evaluated.

the observed gravity changes we consider next the possible sub-surface causes. (1) Assuming 30% porosity for the volcanic edifice, vertical water table movements of 10–20 m could produce the observed gravity changes. However, observations were made during the dry season; moreover, the crater lake level remained constant, so water table fluctuations are rejected as the cause. (2) A periodic change in shape of the shallow magma body is a possibility, but the similarity of observed gravity changes at the rim stations makes this less likely than changes in the depth and/or density of the magma body. (3) Given a maximum density contrast of 500 kg m^{-3} for the unvesiculated magma of the cylindrical body and the surrounding ash–lava sequence, and a probable depth of 100 m, then a rise and fall of the density interface through 10 m would produce the observed gravity change at R7. However, the contrast in density between the magma body and the overlying solidified rubble is probably less, so that the gravity changes can be explained only partially in terms of independent vertical movement between the magma body and surrounding volcanic cone. (4) The final possibility is that the overall density of the magma body is varying: changes of 5–10 kg m^{-3} throughout the entire body, or greater changes confined to the upper parts are required. In the interpretation of gravity changes related to eruptions at Pacaya, Eggers[10] noted that variations in the degree of vesiculation of the magma (related to the periodic rise of gas bubbles) or in its crystallinity, may cause changes of density, and hence gravity, of the magnitude observed at Poás.

While a more complete analysis would be premature, we conclude that periodic gravity changes at Poás volcano are due to a combination of depth and density changes in the sub-surface magma chamber: the process is cyclic with a period of ~30 days. However, the only appropriate external driving force, the lunar synodic tide, is weak compared with the diurnal and fortnightly tides for which we do not observe a response. The observed periodicity is, therefore, either a primary feature of the Poás volcanic plumbing system, unrelated to tides (compare with natural gravitational oscillations observed elsewhere but of random periodicity[20]), or is due to tidal resonance at a synodic period (Fig. 2).

This work has shown that previously-unrecognized periodic changes in gravity, unrelated to eruptions, can occur over a stable volcano. There are clear implictions for monitoring non-stable volcanic systems in which, for example, catastrophic build-up of pressure may be recorded in dramatic changes to the amplitude and periodicity of steady-state gravitational change.

We thank many friends and colleagues who contributed to this work, particularly R. S. Thorpe, C. A. Locke and M. Randal for field assistance, R. Edge (IOS, Bidston) for discussion of tidal gravity, and A. W. Shelton and A. Eggers for stimulating reviews of an earlier manuscript. Financial assistance from the Royal Society and the co-operation of the Servicio de Parques Nacionales de Costa Rica are gratefully acknowledged.

Timing the increase in atmospheric sulphur deposition in the Adirondack Mountains

George R. Holdren Jr*, Thomas M. Brunelle*, Gerald Matisoff† & Martin Wahlen‡

The timing and magnitude of increases in the flux of atmospherically-derived anthropogenic substances to remote areas can be estimated from their distributions in lake sediments. For transition metals[1–4] or trace organics[5–7], this is done simply by comparing their distributions with that of geochronological tracers. This approach is not directly applicable to species which exhibit significant post-depositional mobility. Diagenetic mobilization must be assessed from the distribution of the species in the sediment pore waters. However, by using this and related information, loading histories can be calculated. We have done this for sulphate, the major anionic component of modern precipitation[8–11], for a watershed located in the Adirondack Mountains of New York State. Our results suggest that previous estimates for the onset of increased sulphur deposition in eastern North America[12,13] are too old by a factor of about two, and that significant increases did not occur until about 1930.

In the sediments of softwater lakes, sulphate is converted to both organo-sulphur compounds[14–16] and mineral sulphides[17,18]. In non-acidic systems[19], the rates of conversion are proportional to the sulphate concentration in the lake water[20]. Sulphate is transformed to these immobile forms over a finite interval within the sediment column[21,22]. As a result, a part of the 'modern' sulphur is transported downward to 'older' sediments before

Table 2 Model parameters, their values and the methods of evaluation

Symbols	Definition	Value	Source
$S(z, t)$	Total sedimentary sulphur concentration	Variable	Measured
$S(0, t)$	Detrital sulphur input to sediment	0.16 wt %	Estimated using model
$SO_4(x, t)$	Profile of pore water sulphate concentrations	Variable	Measured for modern values
$SO_4(0, t)$	Lake-water SO_4 concentration	t = 1982–80 μM t < 1920–10 μM	Estimated using model
ω	Sedimentation rate	0.25 cm yr^{-1}	$^{210}Pb_{xs}$
z	Depth below sediment–water interface within sediment column (positive downward)		
X_1	Depth of oxic sediment zone	≈2 cm	Measured
X_2	Depth of bioturbated zone	4 cm	Measured
D_B	Biological mixing coefficient	3×10^{-8} $cm^2 s^{-1}$	Calculated from $^{210}Pb_{xs}$, $S(z)$ and Pb_{Total} profile
D_{SO_4}	SO_4^{2-} diffusion coefficient	4.5×10^{-6} $cm^2 s^{-1}$	Ref. 30
R	SO_4^{2-} reduction rate parameter	0.38 cm^{-1}	Calculated from SO_4^{2-} profile data
Φ	Porosity	0.91	Measured
ρ	Bulk sediment density	1.11 g cm^{-3}	Measured

becoming fixed in the sediment solids. Upward mobilization of the sulphur, as sulphide, also occurs. However, this transport is only a fraction of that observed for sulphate, and, therefore, is not a significant factor in controlling the observed distributions of total sedimentary sulphur.

Because the reactions are microbially mediated—it has been demonstrated that microbial activities can be either enhanced by eutrophication[23], or depressed by acidification[19]—and because of certain constraints needed to do the following calculations, it is important that the study area be only minimally perturbed by encroaching civilization. Our study was conducted in Grass Pond, Herkimer Co., New York State (43°41.5′ N × 75°3.5′ W). The pond has a maximum depth of 5.3 m and an area of ~2 ha. The 210-ha watershed is covered by a predominantly deciduous forest and is largely undisturbed. There are no roads or human dwellings within the watershed. The *p*H of the largest perennial stream in the basin averages ~6.8–6.9, except during snow melt. The smaller, ephemeral streams tend to have lower *p*H values, with at least one which has an average *p*H of ~4.3. In spite of these acidic contributions, typical summer and autumn *p*H values in Grass Pond are in the range 6.4–6.8.

Diver-operated piston cores were retrieved from the pond in May 1981 and in August 1982. The cores were returned to Rochester, sectioned and frozen within 48 h of collection. These samples were used for the determination of several parameters including total sedimentary sulphur, total organic carbon, water content and $^{210}Pb_{xs}$. Pore water data were obtained using a peeper[24] which was placed in the pond in August 1982 and retrieved in November 1982. The results of these measurements are summarized in Table 1.

Because sulphate exhibits post-depositional mobility, it is necessary to use model calculations to extract information regarding the timing and magnitude of increased atmospheric fluxes of sulphur to this basin. This can be accomplished using a mass balance equation in which the diffusion, reaction, burial and biological mixing of the sediments are considered. We have done this using a one-dimensional, diagenetic equation[25] of the form:

$$\frac{\mathrm{d}S(z,t)}{\mathrm{d}t}=\frac{\partial}{\partial z}D_{\mathrm{B}}\frac{\partial S(z,t)}{\partial z}+\omega\frac{\partial S(z,t)}{\partial z}+P(x,t)+\frac{\partial S(0,t)}{\partial t} \quad (1)$$

where

$$P(x,t)=\frac{\Phi D_{\mathrm{SO}_4}}{\rho(1-\Phi)}\frac{\partial^2\mathrm{SO}_4(\mathrm{x},\mathrm{t})}{\partial\mathrm{x}^2} \quad (2)$$

and

$$\mathrm{SO}_4(x,t)=\mathrm{SO}_4(0,t)\exp(-R(z-X_1)) \quad (3)$$

Individual terms are defined in Table 2. Equation (2) describes the instantaneous mass accumulation of solid sulphur based solely on the observed changes in the gradients of dissolved sulphate (equation (3)). By integrating this over time, which we have done numerically, and combining the results with equation (1), a profile of total sedimentary sulphur can be computed for any given sulphate loading history.

Modern-day values for all of the parameters used in the calculations, except the detrital sulphur concentration, can be derived directly from the field data. In the absence of historical information, we have assumed that these have remained time invariant. The two most poorly known, time-dependent parameters include the detrital sulphur concentration and the lake-water sulphate concentration. The detrital sulphur concentration cannot be measured directly because sedimentary sulphur is an admixture of detrital and diagenetically-derived material at all depths in the sediment column[21,22]. The lake-water sulphate concentration is related to the atmospheric loading history, and, ultimately, is the information to be extracted from this calculation.

To evaluate these two parameters, steady-state, sedimentary sulphur profiles[26,27] (curve *a* in Fig. 1) were calculated using various combinations of detrital sulphur and lake-water sulphate concentrations. Based on the results of these mass balance computations, the most reasonable value for preanthropogenic, detrital sulphur is 0.16 wt%, and for lake-water sulphate concentration is 10 ± 2 μM. Compared with the present day sulphate concentration of about 80 μM, this suggests that loadings in the Grass Pond watershed have increased eight- to 10-fold during this century. This is in excellent agreement with estimates made by Galloway and Whelpdale[28]. Changing either of the parameters requires a concurrent change in the value of the other to maintain the mass balance. For example, if preanthropogenic lake-water sulphate concentrations averaged 20 μM, detrital sulphur concentrations would have accounted for only 20% (0.05 wt%) of the total sedimentary sulphur. Alternately, if detrital contributions accounted for 88% (0.22 wt%) of the sedimentary sulphur, then lake-water sulphate concentrations could not have exceeded about 4 μM.

To determine the timing of changes in the sulphate loading rates, presumed loading histories were incorporated into the computation. Steady-state conditions were assumed to prevail into the twentieth century when sulphate concentrations began to increase towards present day values. These modelled increases ceased in 1965, because trend analyses of sulphate loading rates in the region suggest that these values have been constant to within 20% during the past 20 yr (ref. 29).

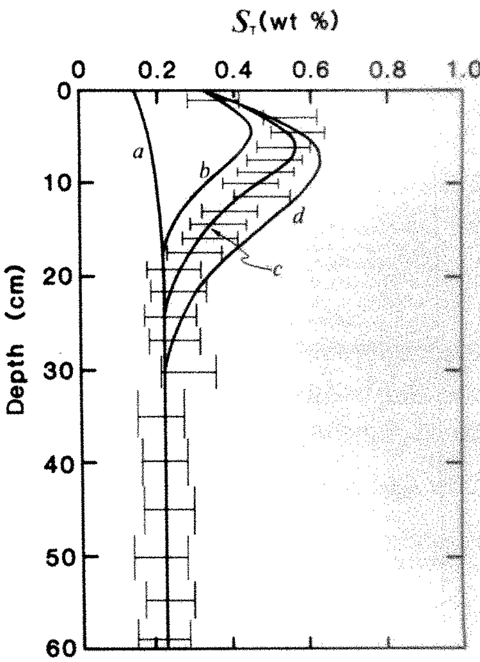

Fig. 1 Comparison of the measured versus model profiles for total sedimentary sulphur in the sediments of Grass Pond. Measured sulphur concentrations are indicated by the barred symbols. The heavy lines represent the results of the model calculations. *a*, Best estimate for the preanthropogenic, steady-state profile. *b*, *c* and *d* show the profiles computed assuming an onset of increased sulphate loading to Grass Pond beginning in 1950, 1935 and 1920, respectively.

Comparison of the model results with the field data permit a clear estimation of the timing of increased sulphur loading to the Grass Pond watershed. Curves *b*–*d* in Fig. 1 illustrate the comparison between three model curves and the field data. Curve 1*b* was calculated assuming that sulphur loading rates began to increase in 1950; curve *c* corresponds to an increase beginning in 1935; and curve *d* to 1920. From these results, it seems that increased sulphur deposition began in Grass Pond during the early to mid-1930s.

This timing estimate contrasts sharply with that which would have been made had the mobility of the sulphate not been taken into consideration. Excess sedimentary sulphur concentrations appear at a depth of ~23 cm in these sediments, or, based on the $^{210}\mathrm{Pb}_{\mathrm{xs}}$ data, in sediments which were being deposited in the 1880s and 1890s. Although these presumed dates are consistent with previous estimates for the onset of increased atmospheric deposition of 'pollution' sulphur in eastern North America[11,12], they are too old by a factor of about two when post-depositional mobility is taken into consideration.

We thank R. C. Aller, R. A. Berner, O. P. Bricker, W. Casey, G. E. Likens, and J. O. Nriagu for helpful comments. S. Matis and A. Pfordresher performed the total sulphur and carbon analyses reported.

Toluene degradation products in simulated atmospheric conditions

Bruce E. Dumdei & Robert J. O'Brien

Chemistry Department and Environmental Sciences Doctoral Program, Portland State University, Portland, Oregon 97207, USA

Atmospheric hydrocarbons have an important influence on the chemistry of the polluted lower atmosphere. Aromatic hydrocarbons or benzene derivatives comprise about 25–40% of gasoline in the US[1] and they are widely employed as solvents. Toluene is the most commonly used aromatic hydrocarbon and is often the most abundant of all non-methane hydrocarbons in urban atmospheres. Typical urban toluene concentrations range from 1 to 50 p.p.b. (parts per 10^9)[2,3] and clean-air concentrations up to 0.4 p.p.b. have been reported[4]. The aromatic hydrocarbons are destroyed by reaction with atmospheric hydroxyl radical (HO) and toluene remains in the atmosphere for about 50 daylight hours before reacting. Despite extensive study, toluene's reaction products are poorly understood[5]. Many reaction products have been identified, but most of these are ring-addition or side-chain oxidation products which retain the aromatic character of toluene. We have conducted a thorough study of toluene's oxidation products in simulated atmospheric conditions and present here an account of the products found and outline their probable formation and destruction mechanisms.

The simulated atmospheric reactions were carried out in hydrocarbon-free Pyrex vessels by black-light irradiation of toluene and nitrogen oxides (1–10 p.p.m. each) in zero-air at 50% relative humidity. This irradiation produces hydroxyl radical, and reaction conditions were adjusted to suppress ozone formation. Past failure to detect ring-opened fragmentation products of the toluene/HO reaction has been due, at least in part, to their precipitation from the gas phase onto the walls of the reaction vessel[6]. In the present experiment, products were recovered by solvent extraction from the vessel walls after 24–30 h irradiation. During this period, 60–80% of the toluene reacted. The solvent extract was concentrated and analysed by direct probe insertion into a Finnigan MAT triple stage quadrupole mass spectrometer/data system[7] (MS/MS)[8]. In addition to normal (H_8) toluene, methyl-deuterated (D_3) and perdeuterated (D_8) toluene were reacted to clarify the mass spectral interpretations. Product identifications were based on collision-induced-dissociation (CID) spectra.

Table 1 lists all compounds identified in this study. Of the 27 compounds, only 10 have been previously identified[9–15]; four others have been proposed[16–18], although never identified. The previously identified products are those amenable to gas-phase sampling and analysis by gas chromatography (GC) or gas chromatography–mass spectrometry (GC/MS).

Products missing from Table 1 are the low molecular weight gaseous compounds, such as carbon monoxide, carbon dioxide, acetylene, methylnitrate, peroxyacetylnitrate, formaldehyde, and formic acid, which have been previously identified as products of toluene. These compounds are either unlikely to partition into the solvent, are expected to be easily lost during the con-

Table 1 Identified products

* Identified. † Proposed only. ‡ Several isomers possible.

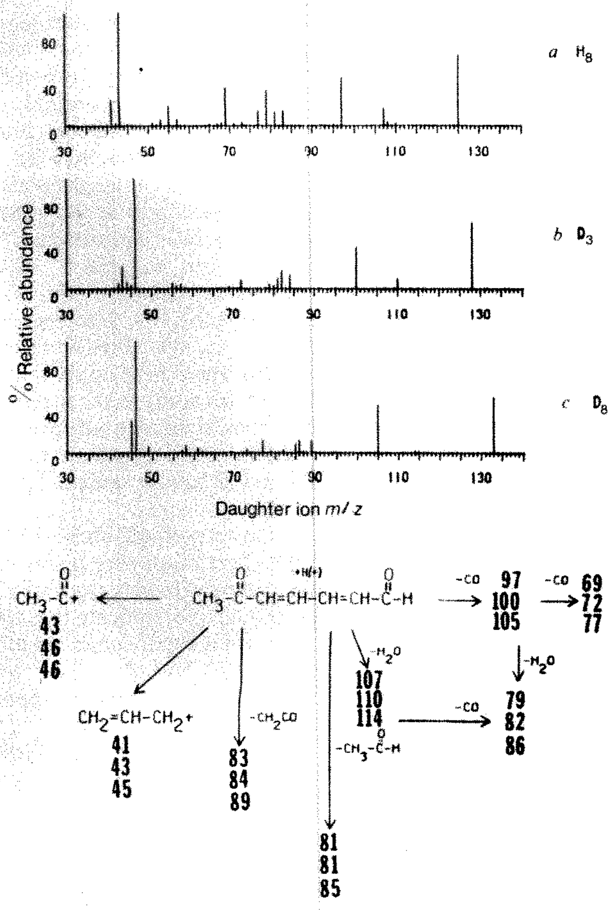

Fig. 1 Identification of 6-oxo-2,4-heptadienal. The $M+H^+$ ion was subjected to collision-induced-dissociation (CID) in its three isotopically-labelled forms. The three daughter-ion spectra are shown in *a, b, c* and the fragments are mass-shifted in agreement with the deuterium labels. *d*, A fragmentation scheme which confirms the identity of the parent molecule.

centration of the solvent, or occur at too low a mass to be scanned in all modes effectively. Six tentatively identified ring fragmentation products found by Schwartz[10] were not found in this study.

With the exception of benzylnitrate, none of the nitrate products hypothesized by Atkinson *et al.*[18] were found by this analysis. This is in agreement with a kinetic study[19] which attributed all NO_x loss before ozone appearance as being due to nitric acid formed in the reaction of HO with NO_2. Daughter spectra were taken at m/z corresponding to the major predicted nitrates. Additionally, neutral loss spectra[8] were taken at the possible major fragmentations: neutral loss of 17(OH), 30(NO), 46(NO_2), and 62(NO_3) mass units. In none of these spectra was there evidence for other nitrate products in the samples analysed. These compounds should have been detected if they were formed in yields as proposed (~25%). Benzoic acid and acetic acid were the only acids identified by MS/MS, and they were minor products. Acids as a group are easily recognized by their predominant fragmentation loss of 44 mass units (CO_2).

The product identification procedure is illustrated by the mass spectra shown in Fig. 1 for the compound 6-oxo-2,4-heptadienal. The three isotopic forms are shown: H_8 in Fig. 1*a*, D_3 in Fig. 1*b*, and D_8 in Fig. 1*c*. The deuterium mass-shifted fragments are in agreement with the proposed CID fragmentation processes shown in Fig. 1*d*. Spectra similar to these were obtained in all three isomeric forms for all compounds reported in Table 1. In some cases, the fragmentation patterns did not allow a choice to be made between several methyl- or hydroxyl-positional isomers, and more than one isomer was often present, as would be expected. Compounds with the same molecular weight but with different numbers of hydrogen atoms will have their molecular weight shifted to a different mass in the deuterium studies. The compounds will be given elsewhere[20].

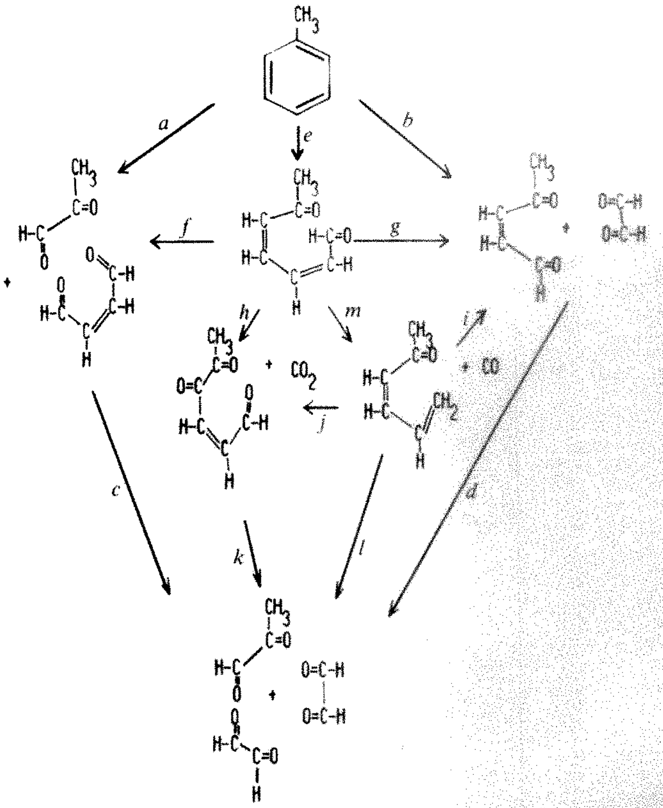

Fig. 2 Reaction pathways for the major ring fragmentation products of toluene which contain only the carbonyl moiety. All processes except *h* and *m* involve attack of hydroxyl radical at a double bond in the reactant. Process *h* involves abstraction of an aldehydic hydrogen. Process *m* is photolysis. Following the rate-determining hydroxyl attack, reactions such as shown in Fig. 3 produce the indicated products.

All of the compounds identified in this study have reasonable production pathways from toluene reacting under simulated atmospheric conditions. Following HO attack, further reactions with molecular oxygen and nitrogen oxides produce stable products and regenerate hydroxyl radicals. The specific reactions to produce the aromatic products are well understood[5,16-18]. Reactions similar to these can be used to explain the other aromatic products; hydroxybenzaldehydes, dihydroxytoluenes, nitrobenzaldehydes, nitrocresols, and dinitrotoluenes. The minor product phenol probably results from secondary reactions of benzaldehyde[17].

Figure 2 presents probable pathways for production of the major ring fragmentation products containing only the carbonyl group. Although many of the compounds in Fig. 2 have not been identified previously, several pathways have been proposed. These pathways are reactions *a–e* in Fig. 2. References for proposed formation of these and other compounds can be found in Table 1. Reactions *f–l* have not been previously proposed. They involve reaction sequences similar to those in *a–e*. Reaction *m* in Fig. 2 is the photolytic loss of carbon monoxide from 6-oxo-2,4-heptadienal. Similarly, hydroxy-5-oxo-1,3-hexadiene, 3-oxobutene and hydroxy-3-oxobutene are possible photolysis products of hydroxy-6-oxo-2,4-heptadienal, 4-oxo-2-pentenal and hydroxy-4-oxo-2-pentenal respectively. The photochemistry of these molecules is unknown. Photolytic loss of CO is common for some aldehydes, but propenal and *trans*-2-butenal do not show significant CO production at normal (25 °C) temperatures[21]. Although this pathway could explain the formation of products with a terminal methylene group, toluene's measured carbon monoxide yields are only 15% (ref. 6).

An alternative mechanism which would lead to these products is a 1,2-hydrogen shift after initial hydroxyl radical attack. This

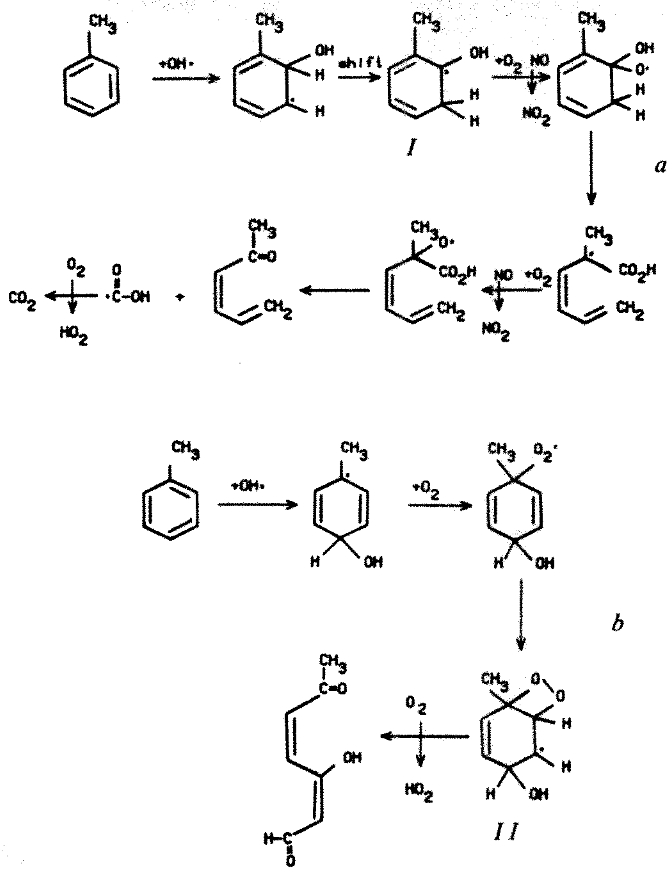

Fig. 3 New reaction pathways for two new toluene products identified. *a*, Reactions producing 5-oxo-1,3-hexadiene involve a initial hydrogen shift and ultimately produce a product containing a terminal methylene group as well as CO_2. *b*, Reactions producing 3-hydroxy-6-oxo-2,4-heptadienal. Mechanisms such as this retain the hydroxyl radical moiety in the ring-opened product.

mechanism is shown in Fig. 3*a*, where the hydrogen-shifted adduct *I* proceeds through reaction sequences similar to those proposed for the other ring fragmentation products. This reaction pathway leads to the production of 5-oxo-1,3-hexadiene and carbon dioxide. The reactions in Fig. 3*a* would help to explain the direct formation of carbon dioxide that we have observed[6]. Similar reaction sequences can be formulated for the other products containing a terminal methylene group. The 1,2-shift proposed in Fig. 3*a* has been observed in the closely related attack of $O(^3P)$ on toluene[22].

The hydroxy products identified in this study have two reasonable formation mechanisms. They may be formed from the primary product cresol reacting along similar fragmentation pathways as toluene. Because the primary cresol yield is low, only small amounts of these products would be expected from this route. An alternative reaction mechanism is shown in Fig. 3*b*. The hydroxy-product results from hydrogen abstraction from the oxygen-cyclized adduct *II*, rather than from oxygen addition leading to methyl glyoxal and glyoxal formation. Such a mechanism probably dominates over cresol reactions in forming products with the alcohol group. Although these compounds are isomeric with the corresponding acids, lack of CO_2 loss in the CID fragmentation argues against this structure.

Although the present work is basically a qualitative study, analysis[20] of the mass spectral product intensities indicates that most of the ring-fragmentation products listed in Table 1 contribute significantly to the reaction mechanism. Current mechanisms[16–18] depict a much simpler scheme, producing only a few of the products in Table 1. Although our structural assignments confirm previously proposed pathways of ring fragmentation, new pathways (Fig. 3) are required to explain the prevalent formation of products containing the terminal methylene group and containing the hydroxyl (alcohol) moiety. The latter class of compound is significantly more polar and will have a much lower vapour pressure than the corresponding carbonyl-containing species which lack the hydroxyl group. Incorporation into aerosols or precipitation may be important. Photolysis of the numerous aldehyde and ketone intermediates may be a significant source of atmospheric free radicals in the gas phase and perhaps also in aerosols or clouds. Failure to detect either nitrates or carboxylic acids in this study has implications for the acidity of precipitation. It has been suggested[23] that carboxylic acids can contribute significantly to such acidity. On the other hand, incorporation of atmospheric NO_x into organic reaction products would lessen the quantity available for oxidation to nitric acid. Note that results presented here apply to the HO/toluene reaction. The extension of this study to the reaction of ozone with the unsaturated products from toluene is desirable, due to the likelihood of acid formation in the ozone reaction[23] and nitrate formation in the reaction with nitrate radical[24] produced from NO_2 and O_3.

The significance of toluene's reactions in polluted air is widely acknowledged, primarily due to the effect of alkylbenzenes on ozone formation in photochemical smog. However, clean-air measurements[4] of toluene as high as 0.4 p.p.b. indicate that the mechanisms inferred here may have wider significance. At this upper concentration, the oxidation rate by HO of toluene represents ~20% of the methane oxidation rate. Although methane has long been presumed to dominate organic clean-air chemistry, products from toluene are more numerous and probably more reactive than the formaldehyde or methylhydroperoxide produced from methane. The very low NO_x concentrations in clean air relative to polluted air will negate formation of nitroaromatic products, and will influence the yields of the ring fragmentation products by curtailing NO reduction of peroxyl radical intermediates. For example, the processes shown in Fig. 3*b* would dominate over those in Fig. 3*a*, which require NO as a reactant. It seems safe to assume that the reactions of toluene and other nonmethane hydrocarbons are making an increasing and probably significant contribution to global tropospheric chemistry.

We thank Dr S. V. Hummel for carrying out the MS/MS analyses, Dr R. P. Yost for use of his instrument, and both for helpful discussions. R.J.O'B. thanks the University of Florida for support and the US Environmental Protection Agency for previous support of this research. P. J. Green provided invaluable assistance in earlier stages of this work.

Natural ^{15}N abundance measurements and atmospheric nitrogen standard calibration

André Mariotti

Université Pierre et Marie Curie, Biogéochimie des Isotopes stables,
Departement de Géologie dynamique T26, 4 Place Jussieu,
75230 Paris Cédex 05, France

Small differences in natural isotope ratios between two compounds can be measured easily and with high precision by using mass spectrometers fitted with double (or triple) ion collectors and dual inlet systems equipped for rapid switching between reference and sample[1–3]. The parameter used to describe these differences in natural ^{15}N abundance is:

$$\delta^{15}N‰ = \frac{R_{sample} - R_{standard}}{R_{standard}} \times 1{,}000$$

where R is the isotopic ratio of $m/z = 29(^{14}N^{15}N^+)$ to $m/z = 28$ ($^{14}N^{14}N^+$). Although an international standard for nitrogen has not yet been defined, atmospheric N_2 had been chosen through practical experience, even before the worldwide homogeneity of its isotopic composition was demonstrated[4–7]. However, the presence of argon ($\simeq 1\%$) in purified air samples may, in some circumstances, modify the apparent isotope ratio of atmospheric N_2. Two different mass spectrometers in our laboratory have been used to assess the magnitude of this 'argon effect', which seems to be essentially an instrumental, presumably pressure-related, effect. Therefore, on mass spectrometers showing this argon effect it is imperative that a correction be applied to measurements of $\delta^{15}N$ of atmospheric N_2. However, in some circumstances (different mass spectrometers, different tuning of the same instrument) this effect can be non-existent or negligible and might require no correction whatsoever.

I have previously described[7] a simple method for the preparation of atmospheric N_2 as a standard for $\delta^{15}N$ measurements. Excellent reproducibility was obtained. This work established the worldwide isotopic homogeneity of atmospheric N_2: the standard deviation in $\delta^{15}N$ of 30 air samples of various origin, measured against one air sample arbitrarily considered as reference, was 0.026‰. Thus, atmospheric N_2 seems to be a reliable standard for ^{15}N natural abundance measurements. In addition, when the variation in ^{15}N abundance is used as the basis for estimating biological N_2 fixation[8], it is essential that an accurate comparison be made between the ^{15}N abundance of plant tissue and of atmospheric N_2. I demonstrated that the various steps in the preparation of atmospheric N_2 as an isotopic standard (deoxygenation, drying, trapping on molecular sieve) did not introduce isotopic enrichments[7]. My data were obtained on a VG 602 D double inlet dual collector mass spectrometer. As it is not possible to eliminate argon in air samples by simple and non-fractionating means, I have used the same instrument to test the side effect of argon on the $\delta^{15}N$ value of nitrogen. No such effect was observed. Some authors (ref. 9 and personal communications from T. Heaton and H. Gerstenberger), however, have found that the presence of atmospheric argon may influence the results of isotopic analyses of atmospheric nitrogen. Heaton (personal communication) pointed out that there is a variable effect which depends on the ion-source focusing of the mass spectrometer. Recently, our laboratory acquired a new triple collector VG SIRA 9 mass spectrometer. During intercalibration between the VG 602 D and SIRA 9 instrument, a small but systematic difference in ^{15}N abundance between atmospheric nitrogen (prepared as described previously[7]) and a secondary working standard (pure tank N_2:99.998%) was observed between the two instruments. No difference, however, was observed between pairs of nitrogen samples without argon. An 'argon effect' was thus suspected. Although Pure tank N_2 is often used as a working standard, data are nearly always reported versus atmospheric N_2. This discrepancy is especially important for precise interlaboratory comparisons. I now suggest a simple method of correcting the measurement of tank N_2 working standard versus atmospheric N_2.

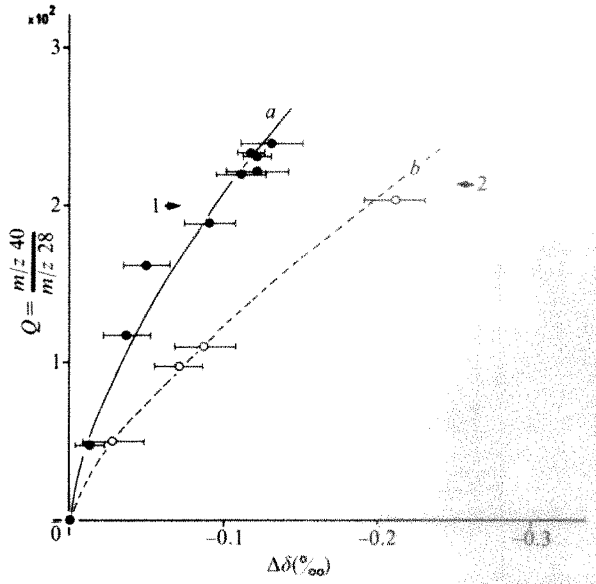

Fig. 1 Effect of increasing quantities of argon on the apparent isotope ratio of nitrogen. Cases *a* and *b* correspond to two different adjustments of the capillary conductance. 1 and 2 represent the *Q* ratio value for atmospheric nitrogen, respectively.

To establish the value of the required correction, pure tank N_2 from the same bottle taken as our daily mass spectrometer standard (N48 pure N_2: 99.998%) was admixed with different proportions (up to 1% v/v) of pure tank argon and stored in evacuated flasks. The ratio, Q, of ion beams in the mass spectrometer corresponding to $m/z = 40$ (argon) and $m/z = 28$ (nitrogen $^{14}N^{14}N^+$) is measured as:

$$Q = \frac{m/z = 40 \text{ ion beam}}{m/z = 28 \text{ ion beam}}$$

For each Q value the apparent isotopic composition of the nitrogen is determined with reference to the same nitrogen when it is argon-free. We define $\Delta\delta$:

$$\Delta\delta = \delta^{15}N \text{ (tank } N_2 \text{ spiked with argon)} \\ -\delta^{15}N \text{ (tank } N_2)$$

These measurements were made on the SIRA 9 mass spectrometer, after optimization of ion-source focusing which was kept constant thereafter. Moreover, all measurements were made with the same gas pressure in the inlet system thus giving the same ion intensity at $m/z = 28$, which is kept as 5×10^{-9}A. These measurements were made for two different capillary conductances, adjusted on both reference and sample sides by means of adjustable crimps[3]. For each Q value, seven or eight measurements of $\Delta\delta$ were made and the mean value determined (standard deviation $\sim \pm 0.02‰$).

An increasing proportion of argon in the nitrogen sample (increasing Q ratio) was associated with a modification of the apparent nitrogen isotope ratio (29/28) which, in the working conditions stated above, was reflected in a lowering of the measured $\delta^{15}N$ value. The relation is not linear (Fig. 1). From these data it is possible to derive an appropriate correction factor to convert the measured $\delta^{15}N$ value to a true $\delta^{15}N$ value. In our present working conditions, this correction is of the order of 0.09‰ for atmospheric nitrogen ($Q \simeq 2 \times 10^{-2}$). Figure 1 also shows that $\Delta\delta$ value as a function of Q is also a function of the capillary conductance. For two different values of this parameter, $\Delta\delta$ is different. In case *a* of Fig. 1 (our present working condition), the capillary conductance, measured by the $m/z = 28$ ion beam value, is 15% lower than in case *b*. On our instrument, the more the capillaries are tightened by means of the crimps, the less is the influence of argon on apparent nitrogen isotope

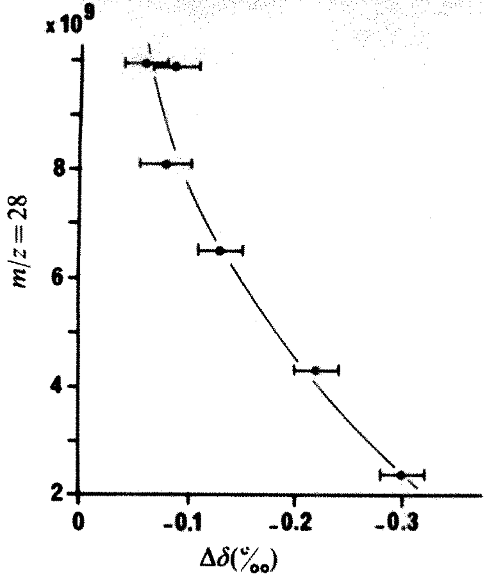

Fig. 2 Effect of the gas pressure in the mass spectrometer inlet system (estimated using $m/e = 28$ v for the ion beam) on the apparent nitrogen isotope ratio in the presence of argon.

ratio. For a pure N_2 sample spiked with argon, we have also tested the influence of gas pressure in the inlet system, adjusted by means of the variable reservoir and estimated through the intensity of ion beam $m/z = 28$. In case *b* (leak rate faster than our present conditions) the increase of gas pressure in the inlet system brings about a reduction of the argon effect on the apparent nitrogen isotope ratio (Fig. 2). With the present condition of capillary conductance (case *a*), this effect is lower. These observations suggest that this effect is presumably pressure related and emphasize the fact that calibration and successive measurements of atmospheric N_2 versus the working standard must be made at the same value of $m/z = 28$ ion current.

Finally, the argon effect may also be modified through tuning of the ion-source focusing. The measured $\delta^{15}N$ value is especially sensitive to the electron trap current (ionizing electron current regulated on the trap electrode) which must be kept at a constant value for the calibration of the correction curve and the further calibration of air nitrogen versus the working standard.

The mean value for several measurements ($n = 30$) using our VG 602 D, an instrument not subject to a detectable argon effect, is 3.4+0.026‰[7] ($\delta^{15}N$ of atmospheric N_2 versus pure tank N_2). The mean of eight different samplings of Paris air measured using the VG SIRA 9 instrument was 3.30±0.02‰ (see Table 1). Air sampled at the same time and at the same location was also measured on the VG 602 instrument (daily procedure); the mean of these measurements (3.39‰) falls within one standard deviation of the value routinely measured on this instrument.

Table 1 Isotopic composition of eight different air samples taken in Paris

Measured $\delta^{15}N_{\text{atmos. }N_2}$ versus bottle N_2	Q ratio ($\times 10^{-2}$)	Corrected $\delta^{15}N$
3.29	1.95	3.38
3.30	1.96	3.39
3.30	1.96	3.39
3.28	1.95	3.37
3.27	1.90	3.37
3.30	2.03	3.42
3.32	1.95	3.40
3.30	1.95	3.39
$\bar{m} = 3.30$		3.39
$\sigma = 0.02$		0.02

The corrected $\delta^{15}N$ is obtained according to curve *a* of Fig. 1.

The value obtained with the SIRA 9 instrument is statistically different ($P < 0.01$) from that obtained on the VG 602 instrument. However, when the argon correction discussed above is applied to the values obtained with the VG SIRA 9 instrument, the mean is 3.39±0.02‰ (Table 1); this corrected value is fully compatible with the previously reported results obtained on the VG 602 instrument.

A correction for possible effects of argon present in atmospheric N_2 prepared as deoxygenated air should be made for each mass spectrometer. Where such effects exist the appropriate steps should be taken to correct for the argon effect to make the precise calibration of a working standard (pure tank N_2 for example, which is very stable with time[7,10]) versus atmospheric N_2. This must be done each time the ion source is adjusted, for example, after a change of filament. This precaution is especially necessary to bring greater validity to the assignment of $\delta^{15}N$ values versus atmospheric N_2 based on interlaboratory comparisons of standards, especially those provided by IAEA (N_1 and N_2 ammonium sulphate[11]).

I thank Professors D. H. Kohl, R. Letolle, F. J. Bergersen and M. C. Clarke for critical reading of and improvements to the manuscript and T. H. E. Heaton and H. Gerstenberger for their personal communications.

Microplankton productivity in the oligotrophic ocean

Ralph E. H. Smith*, Richard J. Geider† & Trevor Platt*

* Marine Ecology Laboratory, Bedford Institute of Oceanography, Dartmouth, Nova Scotia, Canada B2Y 4A2

Uncertainty about the absolute levels of biological productivity over vast tracts of the world's oceans is a fundamental limitation to our understanding of the marine ecosystem[1,2]. Various workers have sought clarification through a comparison of the fluxes of oxygen and carbon in the photic layer[3–5]. A re-examination of data[4] used to compare short-term (<1 day) *in vitro* carbon assimilation with long-term (≈100 day) *in situ* oxygen accumulation at a station in the north central Pacific has shown that the molar fluxes of oxygen and carbon are, in fact, consistent within the resolution of the comparison[6]. This test, however, is lacking in discrimination[7]. A recent comparison of short-term *in vitro* carbon and oxygen fluxes off Hawaii has been interpreted[5] as indicating that short-term (≈12 h) carbon uptake in open ocean regions provides an unbiased measure of gross primary production, P_g. We show here that comparisons of short-term oxygen- and carbon-flux measurements do not provide a powerful test of the accuracy of either of the measurements, both of which can be biased by trophic interactions in the microplankton. Consideration of trophic interactions, implicit in the reported data[5], leads to the important new conclusion that the active biomass of microheterotrophic organisms was large compared with that of autotrophs, a situation which may be generally applicable to the pelagic zone of the open ocean.

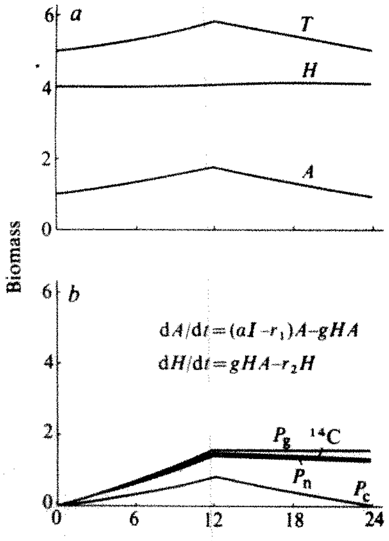

Fig. 1 *a*, The time course (t) of biomass in the total microplankton (T), in autotrophs (A) and in heterotrophs (H) as calculated from the predator–prey model (inset *b*). The photoautotrophic growth rate is αI, set equal to 0.1 h^{-1} for $0 < t \leq 12$ h and zero otherwise. Other parameters were autotroph respiration rate (r_1) = 0.01 h^{-1}; heterotroph respiration rate (r_2) = 0.013 h^{-1}; and grazing rate (g) = 0.0105 h^{-1} biomass^{-1}. Initial autotroph and heterotroph biomasses were 1.0 and 4.0 respectively. *b*, The time dependencies of calculated integral gross (P_g), net autotrophic (P_n), and net community (P_c) productivities and the corresponding productivity which would be calculated from ^{14}C accumulation in the particulate matter. All productivities are expressed in biomass units; parameter and initial values are as in *a*.

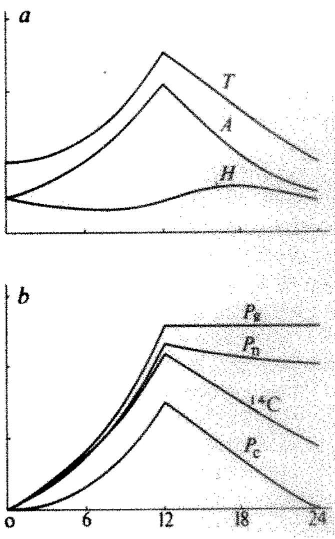

Fig. 2 *a*, The calculated time dependencies of total microplankton, microautotrophic and microheterotrophic biomass. The parameter and initial values used for this simulation are $\alpha I = 0.2\ h^{-1}$ for $0 < t \leq 12$ h and zero otherwise; $r_1 = 0.02\ h^{-1}$, $r_2 = 0.185\ h^{-1}$, $g = 0.080\ h^{-1}$ biomass^{-1}, $A = 1.0$ and $H = 1.0$. *b*, The time dependencies of calculated integral gross, net autotrophic and net community productivities and the corresponding productivity which would be calculated from ^{14}C accumulation in the particulate matter. Parameter and initial values are as in *a*.

The wrong interpretation of *in vitro* molar flux data for biological populations can result from a failure to recognize that a compartmental model of tracer flow through the population is implicit in the calculation of the results[8–10]. The ^{14}C technique[11] depends on measuring the assimilation of tracer inorganic carbon into organic form by photosynthesis, but some of the assimilated tracer carbon may itself be lost due to community respiratory processes. The variability of such losses has long been recognized as a source of uncertainty in the interpretation of ^{14}C-based production estimates[11]. If losses are very small, the ^{14}C estimate can approach P_g, but large losses may greatly reduce the ^{14}C estimate. A particular problem with *in vitro* measurement of autotrophic activity in natural assemblages of open ocean plankton is the lack of discrimination against the activity of microheterotrophs. Their interference with the tracer carbon flux is not the same as their effect on the oxygen flux, and will bias any comparison between the two fluxes. The degree of bias will vary with community structure, in particular with the ratio of the biomasses of microheterotrophs to autotrophs.

The difficulty in accepting the interpretation of Williams *et al.*[5], that 12-h of ^{14}C uptake gives an estimate of P_g, stems from the rapid turnover of microorganisms in the sample they studied. Although the specific growth rate of phytoplankton was as high as 1.2 per day (ref. 12, Table 4) the net change in both pigment biomass and oxygen during 24 h was essentially zero. In other words, the high rate of autotrophic production was in apparent, dynamic balance with consumption and respiration by microplankton. Both autotrophs and heterotrophs contribute to respiration in the incubation bottles. It is easy to show[13] that if autotrophs only were responsible for the respiration, ^{14}C assimilation after 12 h should give a biased estimate of P_g (in fact, a value of ~0.6 P_g). The bias would be less if some physiological mechanism were operating that restricted most of the respiration to the night hours, but then a large diurnal fluctuation in phytoplankton abundance would have been observed. Again, if autotrophic respiration were continuous, but recent assimilate mobilized only at night[14,15], considerable loss of ^{14}C would have been observed during the night hours, which was not the case. If ^{14}C uptake is apparently equal to P_g, as measured by oxygen evolution, the conclusion would seem to be that the high community respiration rate, as implied by a high specific growth rate of autotrophs without biomass accumulation, is predominantly due to microheterotrophs.

We have examined this conclusion using a simple predator–prey model of the Lotka–Volterra type (Fig. 1*b*, inset). We assumed that grazing takes place throughout the 24-h day, but that growth of autotrophs (photosynthesis) occurs only during the light period. The model differs from a recent treatment by Jackson[16] by including the second-order term in heterotrophic and autotrophic biomasses for carbon flow into microherbivores[17]. Both the autotroph and heterotroph pools are assumed to be well-mixed with respect to the tracer, that is, the tracer respires at rates proportional to its specific activity in the pool.

The steady-state solution for constant forcing supplies the initial relationship between the model parameters. Most of the parameters can be fixed through reference to the reported data[5,12]: (1) autotrophic growth rate averaged over 24 h is about 1.2 per day; (2) net biomass change over 24 h (net community productivity, P_c) is about zero; (3) autotrophs comprise only about one-quarter of the total microplankton biomass. Because autotroph respiration rate can be only a small part of P_g, we fixed it at 0.1 P_g, consistent with what is accepted by algal physiologists[18]. The equilibrium conditions can then be solved for the rates of grazing and respiration in the herbivores.

The time course of biomass in autotrophs and heterotrophs was simulated for a 12-h day and 12-h night, and the uptake of ^{14}C (added at the first dawn) calculated over the light–dark cycle. Our simulation reproduces the principal features reported for the natural system: small diel variation in both autotrophic and total microplankton biomass, and little net change in biomass over 24 h (Fig. 1*a*). Despite the rapid system turnover, and the close coupling between autotrophs and heterotrophs, ^{14}C uptake is roughly linear throughout the light period, and is very close to net autotrophic production, P_n, even after 24 h (Fig. 1*b*).

The simulation shows that ^{14}C uptake measured over the light period will yield an apparent carbon assimilation rate practically equal to a simultaneous estimate of P_g by the oxygen method. The oxygen estimate itself will always be too low, due to unequal biomass accumulation in light and dark bottles, which causes respiration to be underestimated (by ~10% in the present case). The considerable and unavoidable random errors in both oxygen- and carbon-flux estimates, together with uncertainty about the true value of the physiologically-variable photosynthetic quotient, will effectively mask the small difference between the two estimates. The uncorrelated, random errors are large, even compared with the difference usually expected between the true, unbiased values of P_g and P_n. It will not, in general, be possible to differentiate between the two (not exhaustive) possibilities that ^{14}C uptake rates measure P_g or P_n, where the standard for P_g derives from changes in oxygen.

Our model, although very simple, accounts for the behaviour of ^{14}C tracer in oligotrophic ocean microplankton near Hawaii. It explains how, in a strictly operational sense, ^{14}C uptake rates might be nearly equal to P_g, in apparent contradiction with the observation that the system is in a state of rapid turnover. But it also reveals that something quite different from P_g is actually measured. A large proportion of the assimilated tracer accumulates in the heterotrophic biomass during the incubation, and ^{14}C uptake measures the retention of carbon in the heterotroph as well as in the autotroph pool. The coincidence in the magnitudes of ^{14}C uptake and P_g is, therefore, a consequence not only of a low autotrophic respiration rate (that is, P_n not very different from P_g) but also of the presence of a large heterotroph population with relatively slow turnover.

Different dynamics may hold in other ocean regions. But because systematic errors scaled to plankton growth rates affect estimates of both carbon and oxygen fluxes, our simple model is not particularly sensitive to the magnitude of its parameters, in so far as the predicted magnitude of apparent photosynthetic quotient is concerned. For example, in the north equatorial current of the Atlantic[3,19,20], pronounced diel fluctuations were reported in oxygen concentration and in particulate carbon concentration. Our model shows (Fig. 2*a*) that large diel fluctuations in biomass may be expected when a relatively small heterotroph population regulates the biomass of a rapidly-growing autotroph population. During the simulated light period, ^{14}C was a reasonable estimate of P_n, in spite of the rapid turnover, but was an underestimate of P_g (Fig. 2*b*). This bias would not have been revealed in a comparison against P_g measured by O_2 evolution *in vitro*, however: respiration in the dark bottle was only ~60% of that in the light bottle, and, therefore P_g would also have been underestimated. The apparent photosynthetic quotient would have been roughly unity, even though both numerator and denominator were biased estimates of P_g. Complete understanding of such a system would require study of the dynamics of both particulate and the ^{14}C tracer throughout the entire 24-h period. Like Jackson, our simulation shows that microplankton grazing alone could not cause ^{14}C uptake during the light period to underestimate P_n by a large factor, as has been suggested[3,19,21].

Our conclusions do not depend on details of the mechanism of carbon transfer from autotrophs to heterotrophs, but on the dominance of the latter in community metabolism and the consequent delay in the respiration of tracer carbon. For example, the microheterotroph biomass at ocean sites is commonly dominated by bacteria[12,22,23] which are presumably nourished indirectly through autotrophic production by a pool of dissolved organic carbon. Despite this difference from our simple predator–prey model mechanism, we may expect that such communities will continue to act as a buffer, delaying the respiration of tracer carbon. Even the detailed kinetics of tracer movement through such communities may be difficult to distinguish from those of a predator–prey model if the coupling between dissolved organic carbon production and consumption is generally as tight as many measurements would suggest[24–26].

We have shown that the presence of a large heterotrophic component, which has been suggested to characterize oceanic plankton[27,28], has a profound regulatory effect on the dynamics of the plankton system, as judged by both the oxygen and the carbon flux. Failure to recognize this in making comparisons betweeen *in vitro* carbon uptake and oxygen·evolution will severely limit the information that can be extracted about the absolute level of productivity in the open ocean. Neither flux provides either a control for the other or an unbiased reference standard for P_g, and an apparent consistency in the observed fluxes is no guarantee that both are free from systematic errors.

Immuno-gold localization of leghaemoglobin in cytoplasm in nitrogen-fixing root nodules of pea

John G. Robertson[*,§], Brian Wells[*], Ton Bisseling[†], Kevin J. F. Farnden[‡] & Andrew W. B. Johnston[*]

Dunedin, New Zealand

A unique feature of nitrogen-fixing nodules formed by association of species of *Rhizobium* and *Frankia* with various legumes and non-legumes is that they contain leghaemoblogin (Lb), an oxygen-carrying myoglobin-like protein[1–6]. Elucidation of the function of Lb, which is thought to facilitate the flow of oxygen to the nitrogen-fixing bacteroid forms of *Rhizobium* within infected nodule cells[7,8], has been hindered by uncertainty regarding its precise intracellular location[9]. Several workers have reported that Lb is located exclusively in the plant cytoplasm in nodules of various legumes[10–12], while others[13–15] have concluded that some of the Lb is located in the peribacteroid spaces in some legumes. Using immuno-gold staining[16] of Lb on thin sections of pea nodules, we demonstrate here that Lb can be detected in the plant cytoplasm and the nucleus of infected cells but not in the peribacteroid spaces.

Good ultrastructual preservation of both nodule and root tip tissue from pea was obtained using the schedule for embedding described in Fig. 1 legend. Immuno-gold staining using anti-pea Lb as the primary antibody on thin sections of 15-day pea nodule tissue revealed specific staining of the cytoplasm of infected

---

[§] Present address: Applied Biochemistry Division, Department of Scientific and Industrial Research, Private Bag, Palmerston North, New Zealand.

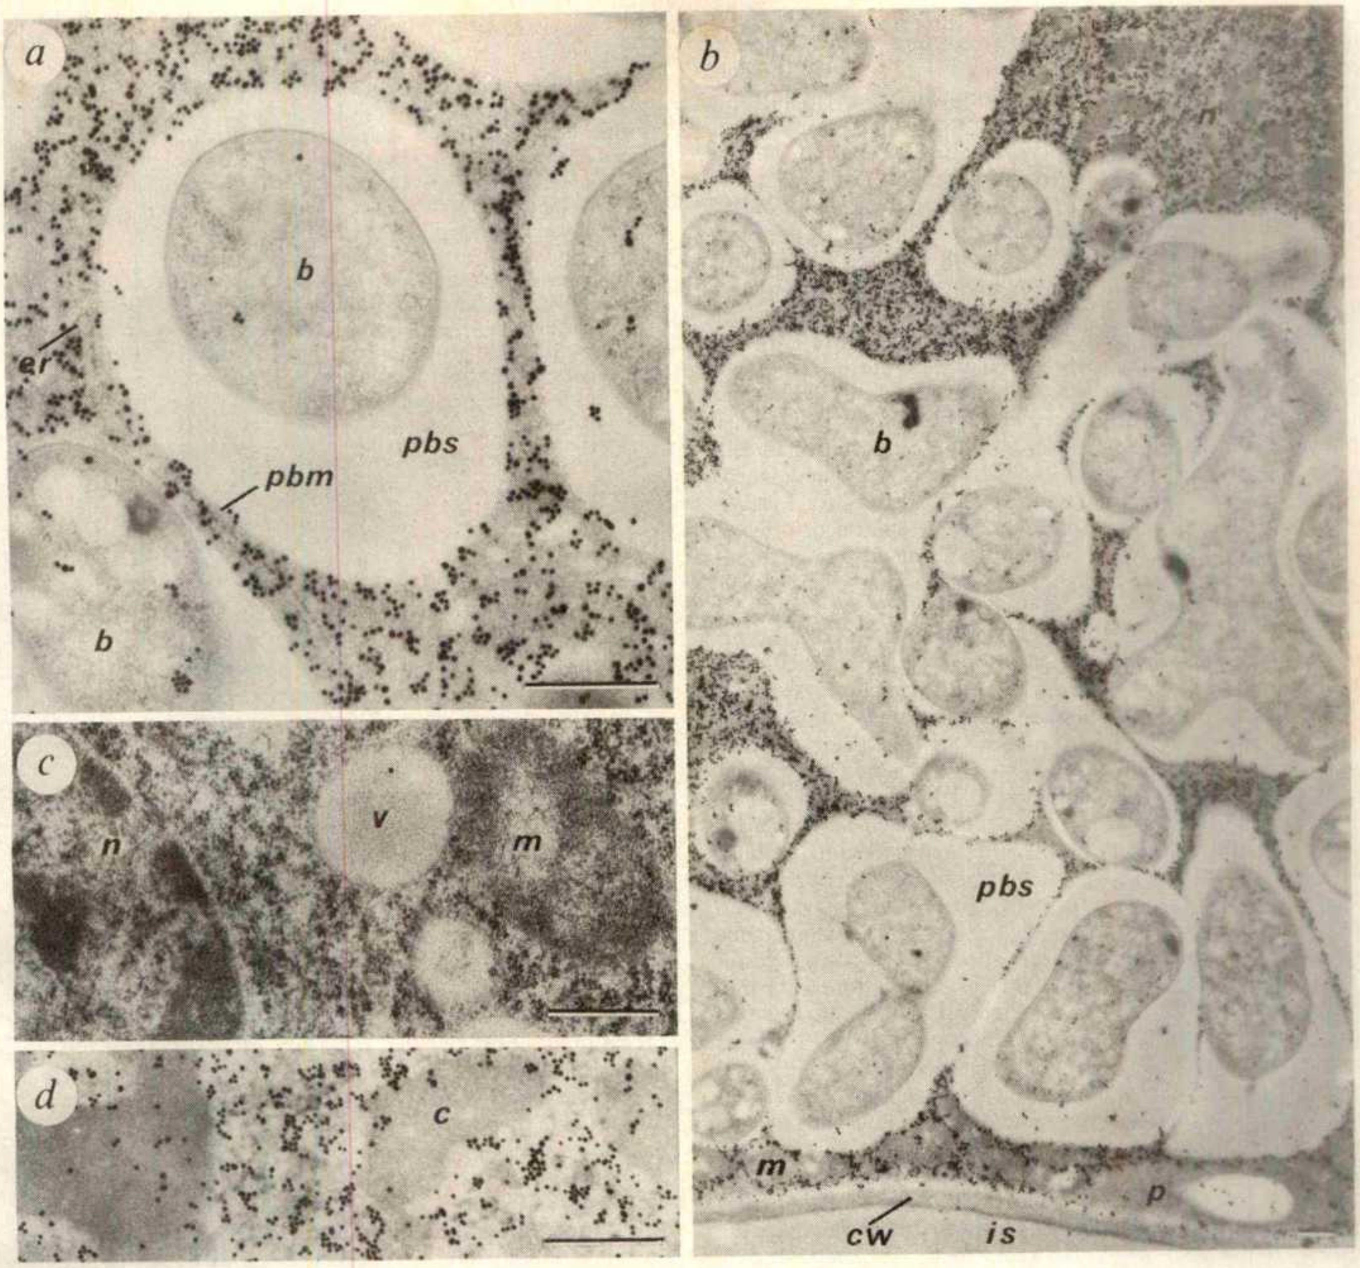

Fig. 1 Immuno-gold staining for Lb of thin sections of 15-day pea nodules and root tips prepared for electron microscopy in Lowicryl K4M. Sections were counterstained with uranium and lead. Scale bars represent 5 µm. *a*, Bacteroid (b) enclosed by a peribacteroid membrane (pbm) in the cytoplasm of an infected nodule cell. Only the plant cytoplasm shows specific immunostaining with gold particles which are sharply delineated from the peribacteroid space (pbs) by the peribacteroid membrane. The endoplasmic reticulum (er) can be distinguished as tracks in the plant cytoplasm which are not generally stained with gold. *b*, Bacteroids distributed in the plant cytoplasm of an infected cell (lower magnification). The nucleus (n) is immunostained with gold. The cell wall (cw), mitochondria (m), plastids (p) and intercellular space (is) show no specific staining. *c*, Section of a non-infected cell from the root tip of pea showing no specific immuno-gold staining of the nucleus, cytoplasm, vacuole (v), or mitochondria. *d*, Section of a nucleus of an infected nodule cell immunostained with gold. The regions of chromatin (c) do not stain as heavily as the non-chromatin regions.

Methods: Nodules were taken from roots of pea plants (*Pisum sativum* var. Wisconsin perfection) grown on agar[27] in a growth cabinet, 11 and 15 days after inoculation of seedlings with *Rhizobium leguminosarum* strain 3688. Nodules of maximum length ~1.5 mm were sliced longitudinally, evacuated and fixed in 2.5% glutaraldehyde, 50 mM cacodylate buffer *p*H 7.2, for 1 h at 22 °C. Dehydration through an ethanol series at 0 °C, −20 °C and −35 °C and infiltration with Lowicryl K4M[26], was done according to the manufacturer's recommendations (Chemische Werke Lowi) in a unit cooled with liquid nitrogen and in which the specimens were rotated at 2 r.p.m. (B.W., in preparation). Polymerization was carried out under UV light (EYE FL20S.BLB) in a −40 °C freezer for 24 h and then at room temperature for 48 h. The pink coloration associated with the presence of Lb in 15-day nodules was visible in the embedded tissue. Root tips ~1 mm long from pea plants were also fixed and embedded. Thin sections were cut on glass knives and processed as follows for immuno-gold staining on 200-mesh gold grids bearing a carbon–Parlodion film which had been glow-discharged. The sections were immersed in bovine serum albumin (BSA, Fraction V; Sigma), 20 mg ml^{-1} in Tris-buffered saline (TBS) containing 10 mM Tris-HCl *p*H 7.4, 9 mg ml^{-1} NaCl, 0.2 mg ml^{-1} NaN_3, 0.5 mg ml^{-1} polyethylene glycol (MW 20,000), for 1 h at 37 °C; immersed in anti-pea Lb antibody (freeze-dried antiserum, 100 µg ml^{-1} in BSA, 20 mg ml^{-1} in TBS) for 1 h at 37 °C; washed with gentle agitation in several changes of BSA, 2 mg ml^{-1} in TBS at room temperature; immersed in goat anti-rabbit IgG–Au(20) (Janssen Pharmaceutica) diluted 1:10 with BSA, 2 mg ml^{-1} in TBS, for 1 h at 37 °C; washed with gentle agitation in several changes of BSA, 2 mg ml^{-1} in TBS at room temperature, followed by the same solution containing 0.1% Triton X-100, and finally with distilled water. Control tests, neither of which gave specific immuno-gold staining, involved the omission of anti-pea Lb antibody from the sequence and inclusion of goat anti-rabbit IgG (Miles) between the anti-pea Lb antibody and the goat anti–rabbit IgG–Au(20). Sections were post-stained with uranyl acetate (20 mg ml^{-1} in distilled water) for 10 min, followed by lead citrate for 2 min[28], and viewed in a Siemens Elmiskop 1A at 80 kV.

Fig. 2 Autoradiogram of an immunoblot showing the specificity of the anti-pea Lb antibody for Lb when blotted against: *a*, the plant cytoplasmic fraction from pea nodules (*Pisum sativum* var. Rhondo); *b*, the peribacteroid space fraction from pea nodules. The methods for purification of Lb, antibody production in rabbits, preparation of the nodule cytoplasmic and peribacteroid space fractions, SDS-gel electrophoresis using 15% polyacrylamide gels and immunoblotting have been previously described[12,17]. 25 μg of protein were applied to each sample well on the gel. SDS-gel electrophoresis of pea Lb yields two components which are only just resolved and which both react with the antibody.

cells (Fig. 1*a*, *b*). No specific immuno-gold staining of the peribacteroid spaces, endoplasmic reticulum, mitochondria or plastids was observed. Determination of the density of gold staining in different cellular compartments (Fig. 1*b*), using a computer programme and graphics tablet (Apple) for measuring the relative areas on electron micrographs, gave a ratio for the plant cytoplasm, peribacteroid spaces and bacteroids of 44 : 1 : 1 gold particles per unit area. This result is consistent with the positive reaction for Lb obtained by immunoblotting the plant cytoplasmic fraction from nodules with anti-pea Lb, and the negative reaction obtained for the peribacteroid space fraction (Fig. 2). Immunoblotting of the bacteroid fraction against anti-pea Lb was also negative (data not shown). Control tests (see Fig. 1 legend) confirmed the specificity of the immuno-gold staining of Lb in the plant cytoplasm of infected cells. No specific immuno-gold staining was observed either in the cytoplasm of pea root tip cells (Fig. 1*c*) or in the cytoplasm of infected cells in the immature 11-day nodules, which were white in colour at the time of harvesting and which contain little Lb[17]. Furthermore, no staining was observed in the cytoplasm of infected cells showing very early signs of senescence in the late symbiotic zone of nodules[18], indicating that Lb was lost very rapidly from such cells.

One unexpected result was that specific staining for Lb occurred in the nuclei of infected cells in 15-day nodules (Fig. 1*b*, *d*). Staining appeared most dense in the non-chromatin areas of the nuclei, and in these areas the density of staining was ~70% of that in the plant cytoplasm of infected cells. Specific immuno-gold staining for Lb was observed neither in the nuclei of infected cells in 11-day nodules nor in nuclei of pea root tip cells (Fig. 1*c*). Staining of Lb in nuclei of infected cells in 15-day nodules was not observed in the control tests used to establish the specificity of immuno-gold staining of Lb in the cytoplasm of infected cells (see Fig. 1 legend). Also, staining for Lb did not occur in nuclei of infected cells in the late symbiotic zone of nodules in which the cells were showing very early signs of senescence. Therefore, it seems that Lb is able to diffuse into and out of the nuclei of the infected cells—this conclusion is consistent with the observation that proteins as large as molecular weight (MW) 150,000 and devoid of specific signal sequences for nuclear transport can penetrate the nuclear envelope[19]. Whether Lb has any functional role in the nuclei is open to conjecture.

The demonstration that Lb could be detected only in the cytoplasm and nuclei of the infected cells in the 15-day nodules substantiates the conclusions of previous studies in which the absence of Lb from the peribacteroid space was established by techniques involving the isolation of bacteroids still enclosed by peribacteroid membranes[10–12]. Localization of Lb in the cytoplasm of infected cells is consistent with studies of *in vitro* synthesis of Lb, demonstrating that newly synthesized soybean Lb does not possess a signal sequence which might allow transport across the peribacteroid membrane[20]. It is also consistent with the finding that the nodule cytosol contains enzymes essential for maintaining Lb in an active state[21,22] and that in some legumes, peribacteroid spaces are not observed[10].

It is apparent from the present results that the role of Lb in facilitating the flow of oxygen to the bacteroids[9] must be restricted to the cytoplasm of the plant cells (Fig. 1*b*). It has been shown that normal rates of nitrogen fixation in nodules from various species of legumes are limited due to resistance to the diffusion of oxygen[23]. Therefore, the spaces between the bacteroids and the peribacteroid membranes might afford a source of resistance to the diffusion of oxygen in some legumes. Also, it has been proposed that the different species of Lb in legume nodules have various functions[24]. Clearly, the mitochondria are bathed in Lb in the plant cytoplasm (Fig. 1*b*) and the implications of this in terms of mitochondrial activity require further study[9]. However, virtually complete development of infected, though non-nitrogen-fixing nodule cells can occur in the absence of functional Lb[25]; although these infected cells tend to senesce prematurely, it follows that the cytoplasmic functions of these plant cells are not strictly dependent on the presence of Lb.

Low-temperature dehydration and embedding techniques[26] coupled with immuno-gold staining[16] have been used previously to localize enzymes in animal tissues but not, to our knowledge, in plant tissues. The present work, together with immuno-gold localization of various enzymes in legume nodules (J.G.R. and B.W., unpublished results), indicates that these techniques have considerable potential for probing the sequence of both plant and bacterial gene expression during infection and nodule development in the legume–*Rhizobium* symbiosis.

We thank E. Carlemalm, J. A. Downie, G. H. Hills, Celia D. Knight and K. Roberts for valuable help and discussions. J.G.R. was supported by a grant from the Trustees of the John Innes Foundation and a Study Award from the Department of Scientific and Industrial Research, New Zealand.

Ratites as oldest offshoot of avian stem—evidence from α-crystallin A sequences

Steven O. Stapel*, Jack A. M. Leunissen*, Marlies Versteeg*, Jan Wattel† & Wilfried W. de Jong*

One of the most disputed issues in avian phylogeny is the origin of the ratites, the large flightless birds of the Southern Hemisphere (reviewed in refs 1–3). It is still not generally agreed whether the ostriches, rheas, emus and cassowaries, and probably kiwis, form a natural, monophyletic group, although much recent evidence supports this view[4–6]. Also, their phylogenetic relationship with the other avian orders remains unresolved; comparative protein sequence studies *might* shed new light on this problem. Therefore, we determined the amino acid sequence of the eye lens protein α-crystallin A in ostrich, rhea and emu, and in representatives of 13 other avian orders. Comparison of these sequences with known αA sequences of mammals, reptiles, frog and dogfish provides strong evidence that the ratites, as a monophyletic assemblage, represent the first offshoot of the avian line.

The α-crystallin A-chain is a suitable protein for comparative sequence analysis because (1) being a major eye lens constituent in all vertebrate classes[7], it can often be isolated in considerable quantities, and (2) the sequence analysis of the 173-residues αA-chain is relatively simple[8]. There is only a single gene for αA[9], which excludes the possibility of errors resulting from comparing paralogous[10] products of multi-copy genes in different species. The rate of evolution of αA is sufficiently slow to be informative in the study of more distantly related taxa[11]. Sequences of αA-chains have been determined previously in 43 mammalian species[8,9], chicken[8], alligator (W.W. de J., M.V., A. Zweers, H. Dessauer and M. Goodman, unpublished data), and tegu[11], frog[8,12] and dogfish[11]. These studies have already provided useful information about some aspects of mammalian phylogeny[11,13], and allow ample outgroup comparisons for the study of avian phylogeny. In the present study we have included, apart from the large ratites, several other avian orders for which the phylogenetic relationships are disputed. To confirm that closely related species indeed have related αA sequences, which would support the reliability of our approach, we included in our study chicken, turkey (both Galliformes), domestic duck and mute swan (Anseriformes). We obtained sufficient eye lenses to perform sequence analysis of the αA-chains from 21 avian species representing 16 orders (Table 1).

The methods of isolation and sequence analysis of the avian αA-chains and the resulting sequence information, as exemplified by the αA-chain of the rhea, are given in Fig. 1 and its legend. The sequence differences between the avian αA-chains are shown in Table 1; relevant sequence data from outgroup species are included. The six mammalian species represent the major lineages of the mammals investigated previously[11]. Table 1 immediately reveals the common occurrence in the ratite species of the unique substitution, Asp 69 → Glu. Another character shared by the ratites is residue Ala 148, which, however, also occurs in pigeon, gull and guillemot. Because Asp 69 and Ser 148 seem to be the primitive character states present in nearly all outgroups, these substitutions may be considered as shared derived (synapomorphous) characters, in support of a ratite monophyly. Equally conspicuous is the presence of Ala 122 and Pro 147 as apparently shared derived characters in all birds, apart from the ratites. Residues Ala 127 (or Thr) and Asn 135 again seem to be synapomorphies of all birds, with the exception of ratites, galliform and anseriform birds.

It is obvious that parallel and back-substitutions do occur in the evolution of αA, as in all other proteins. This complicates the interpretation of differences between homologous amino acid sequences, and necessitates the use of computer analyses to objectively assess the cladistic relationships among the investigated sequences. The objectives of such computer searches are to find the most parsimonious phylogenetic trees (that is, branching patterns that require the fewest amino acid substitutions) and to calculate the cost, in terms of additional required substitutions, of alternative topologies. By applying different

Fig. 1 Proposed amino acid sequence of the rhea α-crystallin A-chain. The characterization of avian αA chains followed the general procedures described for mammalian and chicken αA chains[8]. α-Crystallin was isolated from four rhea lenses by gel filtration of the water-soluble lens proteins, and the component αA and αB chains were separated by ion-exchange chromatography. Fragments produced by cyanogen bromide cleavage of the *S*-β-aminoethylated αA chain were separated by gel filtration and digested with trypsin. Soluble peptides were isolated by paper electrophoresis and chromatography. The core peptide (22–49) was purified by gel filtration, then subdigested with thermolysin for peptide mapping. Peptide 1–11 was obtained by tryptic digestion of the total αA chain. Amino acid compositions of tryptic (↔) and thermolytic (←- - - -→) peptides were compared with the corresponding ones of the chicken αA chain[8]. When no difference in composition was observed, we assumed identity between the chicken sequences and rhea peptide. Peptides which differed in composition from the corresponding chicken peptides were subjected to dansyl–Edman degradation (→) to localize substitutions. Residues which are different in the chicken αA chain are shown above the rhea αA sequence. Cleavage points of cyanogen bromide are indicated by ↓. The avian αA chains are *N*-terminally blocked, probably by an N^{α}-acetyl group as in bovine αA[7].

Positions shown are those which are variable in the αA chains of at least two of the species, plus the autapomorphous substitutions in the avian and reptilian sequences. Vertical lines indicate that residues are identical to the topmost sequence. Amino acid sequences have been analysed, as outlined in Fig. 1 legends, for: carrion crow (*Corvus corone*; Passeriformes), eagle owl (*Bubo bubo*; Strigiformes), budgerigar (*Melopsittacus undulatus*; Psittaciformes), domestic pigeon (*Columba livia*; Columbiformes), guillemot (*Uria aalge*; Charadriiformes), black-headed gull (*Larus ridibundus*; Charadriiformes), curlew (*Numenius arquata*; Charadriiformes), oystercatcher (*Haematopus ostralegus*; Charadriiformes), coot (*Fulica atra*; Gruiformes), buzzard (*Buteo buteo*; Falconiformes), heron (*Ardea cinerea*; Ciconiiformes), gannet (*Sula bassana*; Pelecaniformes), fulmar (*Fulmarus glacialis*; Procellariiformes), gentoo penguin (*Pygoscelis papua*; Sphenisciformes), domestic duck (*Anas platyrhynchos*; Anseriformes), mute swan (*Cygnus olor*; Anseriformes), turkey (*Meleagris gallopavo*; Galliformes), ostrich (*Struthio camelus*; Struthioniformes), rhea (*Rhea americana*; Rheiformes), and emu (*Dromaius novae-hollandiae*, Casuariiformes). The αA sequences and scientific names of the mammals, chicken, tegu, frog and dogfish have been given previously[8,11]. The alligator is *Alligator mississippiensis*. The sequences of chicken and turkey αA were found to be identical, as are those of duck and swan. Some αA sequences have been incompletely determined (·). Thr 127 in heron αA has not been ascertained by Edman degradation, and is therefore not taken as a synapomorphy with penguin αA. In sloth αA there is a deletion of three residues (–). The one-letter notation for amino acids is: A, Ala; C, Cys; D, Asp; E, Glu; F, Phe; G, Gly; H, His; I, Ile; K, Lys; L, Leu; M, Met; N, Asn; P, Pro; Q, Gln; R, Arg; S, Ser; T, Thr; V, Val; Y, Tyr.

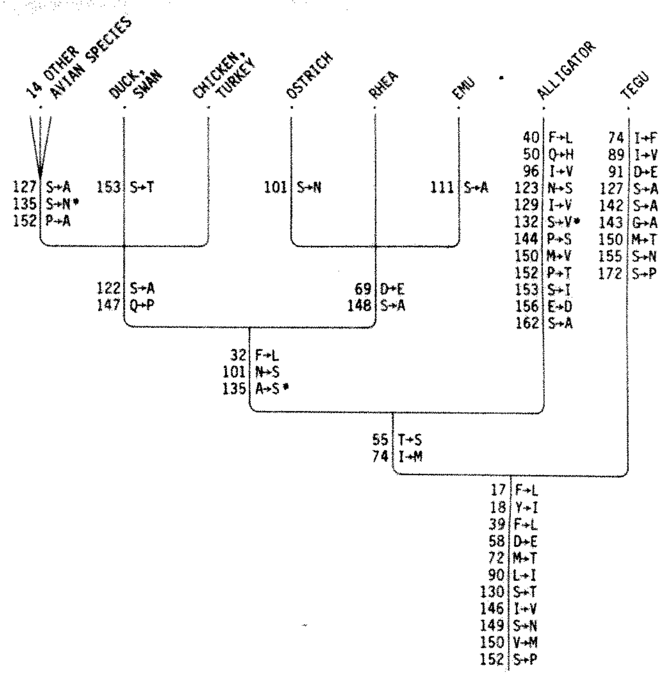

Fig. 2 Avian and reptilian branches of the maximum parsimony tree constructed on the basis of the αA sequence data in Table 1. The procedure starts with the calculation of a matrix of minimum mutation distances for the αA sequences[14], followed by a tree construction programme which begins with an unrooted three-sequence tree to which the other sequences are added one at a time, using a branch-swapping procedure, until a tree of minimal length is found (essentially according to Fitch and Margoliash[14], as modified by J. Felsenstein). The tree construction procedure was repeated several times using different input orders of the αA sequences; this resulted in the same topology in all instances, apart from equally parsimonious minor alternatives in the cluster of 14 'other avian species'. The number of amino acid substitutions required for the most parsimonious tree was 163. The outgroup part of this tree was congruent with the previously constructed topology[11], and is therefore not shown here. Amino acid substitutions in the different branches are deduced from the reconstructed ancestral αA sequences at the nodes[15]. Substitutions that could not be assigned unambiguously to a certain branch were, as far as possible, placed on terminal branches, rather than between ancestral nodes[16]; this minimizes the synapomorphous substitutions characterizing monophyletic groupings in this cladogram. Taking six other mammalian αA sequences (horse, mink, human, elephant, three-toed sloth and opossum)[11] as outgroups in the tree construction procedure resulted in the same topology as shown here. * Substitutions 132 S→V and 135 A→S (or 135 S→N) require two nucleotide replacements.

algorithms[14–16] to the data set of Table 1, we found the most parsimonious tree (see Fig. 2), which requires 163 amino acid substitutions. All changes in the topology presented in Fig. 2 require additional amino acid substitutions (Table 2). On this basis we must conclude that the presence of Ala 148 in ratites and in pigeon, gull and guillemot is due to parallel, or convergent, evolution.

The constructed tree clearly supports the hypothesis that the ratites are monophyletic, and depicts them as the sister group of all other birds. The Galliformes and Anseriformes appear to be the next to branch off from the main avian stem. Our data allow the possibility that Galliformes and Anseriformes are monophyletic[3,4], but conflict with a close relationship between Anseriformes and Charadriiformes[17] (Table 2). The other investigated avian orders are grouped as a monophyletic assemblage, but the scarcity of substitutions in their αA sequences prevents a further, meaningful resolution of their relationships. In fact, several species from different orders are found to have identical symplesiomorphous αA sequences. The most parsimonious tree of αA also stresses the monophyletic origin of the investigated birds and reptiles, and places the crocodiles, represented by the alligator, as a sister group of the birds. These findings conform to the generally held, but not unchallenged, palaeontological views. The recently proposed sister group relationship of birds and mammals[18] would, in the case of αA sequences, result in a considerable loss of parsimony (Table 2).

Also, recent immunological[4] and DNA hybridization studies[6] have provided evidence for a monophyletic origin of the ratites, thus contradicting the suggestion that they are paraphyletic or polyphyletic[2,19]. In fact, Prager and Wilson[20] have suggested a phylogenetic tree, on the basis of immunological comparisons, in which the position of ratites, Galliformes and Anseriformes relative to the other avian orders is essentially as in our αA tree. The primitive, rather than derived, position of the ratites within birds is, among others, also supported by karyological[5] and

Table 2 Numbers of additional amino acid substitutions required to change the topology of Fig. 2

Alternative relationships	Additional substitutions
Polyphyletic origin of ratites from the avian stem	≥4

ontogenetic[21] studies. However, a phyletically old origin of the ratites could not be concluded on the basis of morphological and anatomical data[1-3]. Comparative sequence data of avian proteins, including one or more ratite species, are available for cytochrome c[22] and haemoglobin[23]. On the basis of the very few substitutions in seven avian cytochrome c sequences, a cladogram has been proposed in which the ratites are depicted as derived from carinate birds[22]. We found, however, that a more parsimonious tree can be obtained from this cytochrome c data set by assuming the ratites to be a sister group of the other birds. The sequence determinations of avian α and β haemoglobin have not yet led to specific statements about ratite phylogeny[23].

Our αA sequence data may have some bearing on the problem of the time of radiation of the avian orders. Estimates for the time since the last common ancestor of all modern birds range between 130 and 65 Myr[6,24]. Considering that αA evolves at an average rate of three amino acid substitutions per 100 residues in 100 Myr[8], it seems that the small numbers of substitutions in the avian αA chains since their divergence from the last common ancestor (Fig. 2) favour the more recent time of avian radiation. Finally, the branching order in our tree may lend support to the idea that sustained flight developed late in avian evolution, after the divergence of ratites and Galliformes from the main stem.

We thank Mr W. B. Appel and the Klein Karoo Landboukoöperasie for ostrich lenses, Dr S. J. Davies (CSIRO) for emu lenses, Drs Th. Smit and Ms T. Prins for other avian lenses, and Dr J. Felsenstein for supplying his Phylip package. Closely related sequences on human X and Y chromosomes outside the pairing region

H. J. Cooke & W. A. R. Brown

During meiosis the human X and Y chromosomes form a synaptonemal complex which covers most of Yp and the terminal 30% of Xp (ref. 1). By analogy with the autosomes, this is presumed to reflect DNA sequence homology. It has been suggested that these regions of the X and Y chromosomes contain either related or identical loci which are distal to a site of cross-over[2,3], and support for these ideas has come from the finding that an X-linked cell-surface antigen controlling gene *MIC2* is related to a gene on the Y chromosome[4]. A number of DNA sequences have been shown to occur either on the X and Y chromosomes[5] or on the X, Y and autosomes[6,7]. We have now isolated a sequence from the Y chromosome which is present on Xq and Yq. This region lies well outside the pairing segments, and sequence analysis reveals no base change in 1 kilobase pair (kb). This high degree of similarity between the X and Y chromosomes near the tips of the long arms is a strong indication that interchange can occur in this region.

We have isolated a recombinant phage λY2:13 from a library of sorted human Y chromosomes cloned in λgtWES[8]. Initial hybridization studies using somatic cell hybrids containing only human X and Y chromosomes showed that the 8-kb *Eco*RI fragment cloned in this recombinant hybridized to a fragment of the same size in both somatic cell hybrids and was present in equal amounts in DNA from males and females. A background due to repeated sequences in the cloned probe was evident. To generate probes with a lower repeated sequence content, the fragments produced by *Hin*dIII digestion of the human fragment carried by this phage were subcloned into the plasmid vector pUC9 (ref. 9). One of these subclones (pUC9H1, corresponding to the fragment with sequenced regions a and b in Fig. 1) was used for subsequent hybridization studies although a low level of repeated sequences were still detected by this probe. To confirm the apparent identity of these two sequences on the X and Y chromosomes, we hybridized pUC9H1 to digests of three independently derived somatic cell hybrid DNAs, two containing only the human Y chromosome and one containing only a X chromosome. In all of these cell lines the pattern of fragments detected is identical (Fig. 2) and consistent with the map of λY2.13 in Fig. 1. A trivial explanation of this finding would be that these cell lines carry undetected fragments of the X chromosome (in the Y-containing hybrid) or of the Y chromosome (in the X-containing hybrid). We have probed these hybrid

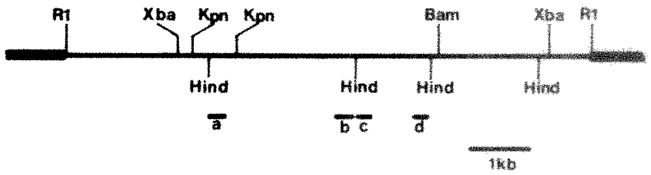

Fig. 1 Restriction map of λY2.13 derived from single and double restriction enzyme digests. Heavy lines are the λgtWES left and right arms. *Eco*RI, *Xba*I, *Kpn*I, *Bam*HI and *Hin*dIII sites are marked. The three *Hin*dIII fragments were subcloned into pUC9, pUC9HI contains the leftmost *Hin*dIII fragment; the lettered regions of these subclones correspond to the sequences in Fig. 3.

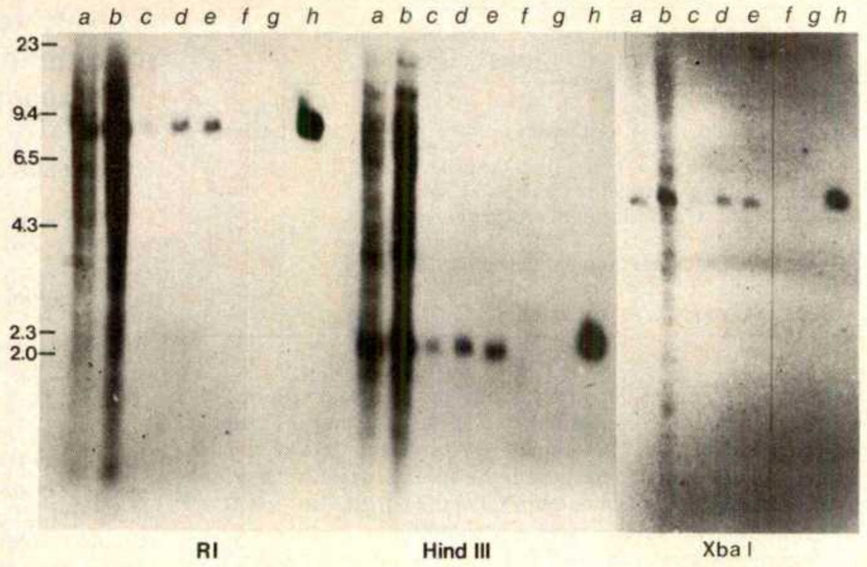

Fig. 2 Hybridization of pUC9H1 to X and Y chromosome sequences. 5 µg of DNA were digested with an excess of *Eco*RI, *Hin*dIII or *Xba*I, fragments separated by electrophoresis on 0.8% agarose gels transferred to nitrocellulose and hybridized with ^{32}P in 5 × SSC, 0.1% SDS 10% dextran sulphate at 65 °C. Final washing conditions were 0.1 × SSC 0.1% SDS at 65 °C. Tracks contain DNA as follows: *a*, human male; *b*, human female; *c*, 3E7—a mouse human hybrid containing only human Y chromosomes; *d*, 853—CHO hybrid with only a Y chromosome; *e*, ThyB1 mouse hybrid with a human X chromosome; *f*, BWS147 mouse control with no human chromosomes; *g*, WG3H chinese hamster control with no human chromosomes; *h*, BWS147 with 75 pg of λY2,13. Differences in intensity of signals are due to differences in loading and additionally in the case of hybrid lines to differences in the percentage of cells containing human chromosomes. Positions of marker fragments are marked with sizes in kb.

Fig. 3 Sequences of the regions of λY2,13 and X11 shown in Fig. 1. *Hin*dIII fragments of each recombinant were cloned in pUC9. Clones containing the appropriate insert in each orientation were isolated, labelled with ^{32}P-ATP after cleavage at the *Bam*HI site in pUC9, digested with *Eco*RI and subjected to Maxam–Gilbert sequencing[11]. Only one strand was sequenced where X and Y clones were identical. Second strands were sequenced where base changes were detected or where the sequence could not be unambiguously determined, by end-labelling with ^{32}P-dGTP at the *Bam*HI site, followed by *Eco*RI cleavage and Maxam and Gilbert sequencing.

DNAs with a number of cloned sequences derived from the X or Y chromosomes and have found no inconsistencies which would suggest this to be the case. We conclude that this sequence is highly conserved between X and Y chromosomes.

To establish the extent of sequence conservation between X and Y chromosomal copies, we have isolated the X chromosomal copy of this sequence from a library constructed from sorted X chromosomes (data not shown) by screening the library with pUC9HI. When pooled DNA from this X-derived library is probed with a sequence known to be X-derived, such as RC8 (ref. 10), the amount of hybridization is consistent with degree of enrichment expected from the chromosome sorting, whereas in the Y chromosome library this sequence is not detectable. This shows that the Y chromosome library is relatively free of X chromosome-derived DNA.

Three recombinants with insert sizes and *Hin*dIII restriction sites identical to λY2.13 were isolated from 4 × 10^4 recombinants. One clone, λX11, was used for sequencing studies. *Hin*dIII fragments from λY2.13 and λX.11 were subcloned for Maxam–Gilbert[11] sequencing into pUC9 (ref. 8). The sequences derived are shown in Fig. 3 and their position on the restriction map of λY2.13 in Fig. 1. All four regions sequenced (in total 1,013 bp) are identical in the X and Y chromosome copies. This suggests that this might be a 'pseudoautosomal' sequence which would be expected to map on the X in the region Xp22 − > Xpter.

A collection of somatic cell hybrids containing X − > autosome translocations with break points in different regions of the X and selected for the presence of the hypoxanthine phosphoribosyltransferase (*hprt*) gene[12] has been used for regional assignment of this sequence by blot hybridization. The sequence is present in all hybrids tested (Fig. 4*A*). The minimum common region of the X chromosome which must contain this fragment, is Xq24 − > Xqter. The hybrid line 445 × 393 contains a Xqter-p233 : Yq11-qter chromosome and consistently shows more intense hybridization than the other hybrids which contain a deleted X chromosome but no Y chromosome fragment. This suggests a Yq11-qter localization of the Y chromosome copy of the sequence detected by pUC9H1. Fragments hybridizing with lower intensities are visible in the hybrid DNAs in Fig. 4. These hybrids contain different human chromosomes and it is likely that these fragments show the residual repeated sequence present in the pUC9H1 subclone. Only one additional fragment is detectable in the hybrid which contains X chromosome as the only human chromosome (Fig. 4*B*, Table 1).

We have used *in situ* hybridization to confirm the X and Y chromosome localization of this sequence. Using λY2 : 13 as a probe, 13.5% of grains counted on 30 chromosome spreads were on Xq24-Xqter, this is entirely consistent with the results of blot hybridization to the hybrid lines shown in Fig. 4. Ten per cent of the grains counted were on the Y chromosome, evenly distributed between two sites, one on Yp and one distal site on Yq. No other significant sites of hybridization were detected. Hybridization to Yp could be due to repeated sequences in Y2 : 13 or to a third copy of the 8 kb fragment. In later experiments pUC9H1 was used as probe to hybrid cell lines CH-Y-VII

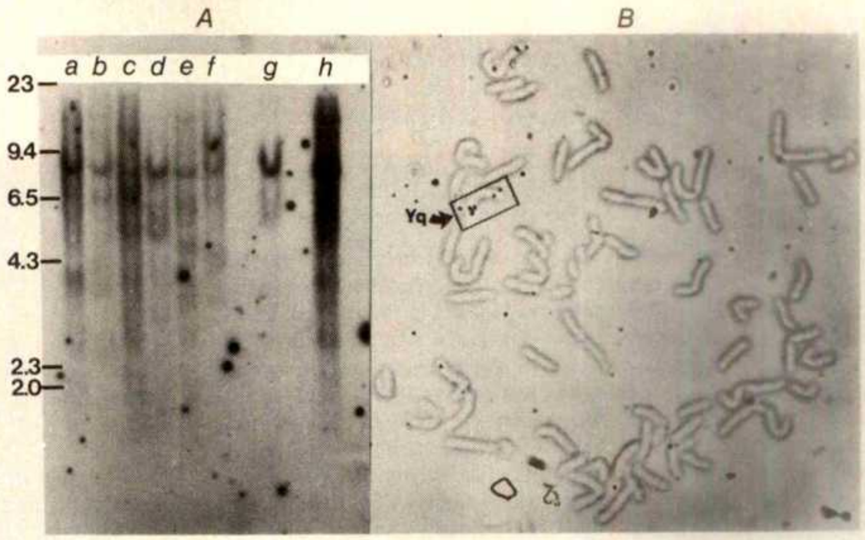

Fig. 4 *A*, Regional assignment of pUC9H1. X chromosome hybrid DNAs with X → autosome translocations were digested with *Eco*RI, transferred to nitrocellulose and hybridized as described in Fig. 2 legend. *a*, 455 × 393, qter-p223; *b*, 697 × 175 qter-p21; *c*, 749, qter-q12; *d*, 676 − 175 qter-q213; *e*, 722 qter p11; *f*, 790 − 175 q24–qter; *g*, ThyB1-33-12–entire X; *h*, Til 46XXXXY human fibroblast. Positions of marker fragments are marked with sizes in kb. *B*, *In situ* hybridization to 445 × 393 chromosomes.

Methods: Chromosome preparations were treated with 70% formamide 2 × SSC at 70 °C for 2 min then dehydrated in ethanol. The slides were then hybridized with 20 ng of ^{3}H-labelled probe with a specific activity of 10^7 d.p.m. per μg in 50% formamide 2 × SSC, 1 × Denhardt's solution, 10% dextran sulphate and 200 μg ml^{-1} salmon sperm DNA at 40 °C for 16–18 h. Slides were washed in 2 × SSC (four 20-min washes) at 68 °C and finally in 0.1 × SSC at room temperature. The slides were dipped in Ilford L4 photographic emulsion and exposed for 2–4 weeks at 4 °C. Chromosomes were identified after autoradiography by quinacrine mustard staining. The boxed area contains the Xqter—p233 : Yq11—qter chromosome. Quantitative evaluation of train distribution was according to ref. 20.

Table 1 *In situ* hybridization of X and Y chromosomes

Clone	Expt no.	Specific activity (c.p.m. per μg DNA)	Cell type	Exposure time (weeks)	No. of metaphase spreads evaluated	Total no. of grains	No. of grains on Y	No. of grains on Yp/Yq	No. of grains on X (%)	No. of grains on Xq2.4–Xqt
2.13	1	2×10^7	CH-Y-VII	1.5	35	140	14 (10%)	7/7	—	—
	2	2×10^7	CH-Y-VII	2.0	35	107	16 (15%)	7/9	—	—
Control	3	—	CH-Y-VII	2.0	35	82	0	0	—	—
	4	2×10^7	CH-Y-VII	2.5	30	298	40 (13.4%)	27/13	—	—
	5	2×10^7	445 × 393	1.0	20	262	19 (7.3%)	−/19	35 (13.5%)	31 (12%)
	6	2×10^7	445 × 393	2.5	30	516	43 (8.3%)	−/43	104 (20.2%)	66 (12.7%)
Control	7	—	445 × 393	2.5	30	171	1 (0.6%)	−/1	5 (2.9%)	2 (1.1%)
pUC 9H1	8	3×10^7	CH-Y-VII	2.0	60	66	11 (16.6%)	0/11	—	—
	9	3×10^7	CH-Y-VII	2.5	30	140	13 (9.3%)	0/13	—	—
	10	3×10^7	445 × 393	2.0	10	58	3 (5.2%)	−/3	14 (24.1%)	13 (22.4%)

Dashes indicate that the chromosome or region of the chromosome is not present in those cells.

(ref. 13) which contains a human Y chromosome and 445 × 393. Ninety CH-Y-VII metaphase spreads were evaluated, 26/206 grains were on Yq. No grains were localized on Yp. This suggests that the Yp localization found for λY2 : 13 is due to the repeated sequences carried by this recombinant. Ten metaphase spreads of 445 × 393 were analysed; of the 58 grains scored, 5% were on the Yq region of the translocation chromosome and 24% on this chromosome in the X region: 23% of the grains were on Xq24-Xqter. It seems likely that the λY2 : 13 sequence is embedded in one or other of the tandemly repeated sequences found on Yq (refs 14, 15).

Such a high degree of sequence conservation between non-homologous chromosomes is striking. Clock rates for base changes in the flanking and non-transcribed regions of the globin genes are about 0.3%–0.4% per million years[16]. Over the 80 million years since the divergence of mammals from a common ancestor, this rate would predict X and Y chromosome homologies of around 70%. If selection were operating to maintain this sequence identity then we would expect to find homologues in the mouse, but hybridization in conditions which should allow detection of sequences with 10% divergence from the human probe reveals no mouse sequences which cross-hybridize. These results show that homologous sequences on the X and Y chromosomes are found in regions which do not form a synaptonemal complex, but the sequence data imply that exchange of DNA sequence between the X and Y chromosomes in the region of this sequence has occurred relatively recently and has resulted in the sequence identity which we have demonstrated. Several homologies between X and Y chromosomes outside the pairing regions have been reported recently[17–19] but the extent of homology varies. This may reflect exchange events of widely different ages.

We thank Edwin Southern for encouragement and comments, Clare Graham for technical assistance and Peter Goodfellow and Ruthi Voss for the gift of cell lines. The work was supported by the MRC and the Deutsche Forschungsgemeinschaft.

Isolation of the *dorsal* locus of *Drosophila*

Ruth Steward, Francis J. McNally & Paul Schedl

Department of Biology, Princeton University, Princeton,
New Jersey 08544, USA

The establishment of embryonic polarity is a crucial step in pattern formation and morphogenesis. In the fruitfly *Drosophila melanogaster*, embryonic polarity depends primarily on genes expressed in the female during oogenesis. Mutations in these 'maternal effect' genes can lead to major disruptions in normal pattern formation. Two classes of maternal genes essential for the establishment of polarity in the embryo have been identified. Lesions in one class, the 'bicaudal' genes, disrupt the anterior–posterior axis[1]; lesions in the other class disrupt dorsal–ventral polarity, and in the most extreme cases embryos fail to form any ventral or lateral structures. Genetic studies suggest that the anterior–posterior and dorsal–ventral axes may be independent as the defects observed in mutants from each class seem to be restricted to one axis only[2]. The *dorsal* (*dl*) locus[2] is one of the maternal effect genes involved in the establishment of dorsal–ventral polarity. Homozygous *dl* females produce embryos exhibiting the mutant phenotype—complete lack of dorsal–ventral polarity in the strongest alleles—irrespective of the genotype of the father. Although *dl* is a maternal effect locus and must be expressed during oogenesis, the gene product, or a substance depending on the normal function of the *dl* gene, seems to be active early in embryogenesis, as the *dl* phenotype can be partially rescued by injection of cytoplasm from wild-type cleavage-stage embryos[3,4]. Here we report the molecular cloning of the *dorsal* locus and a study of its expression.

The *dorsal* locus maps in the cytological interval 36C on the left arm of chromosome 2 (ref. 2). To clone this region and identify the *dl* gene, we took advantage of two inversions, $In(2L)dl^H$ and $In(2L)dl^T$, (R.S. and C. Nüsslein-Volhard, unpublished) which inactivate the gene and hence have breakpoints either within or in close proximity to the locus. Females with the genotype $In(2L)dl^H$ or $In(2L)dl^T$ over the deficiency *Df(2L)TW119* (ref. 5), which uncovers the 36C interval (see Fig. 1), produce embryos which display the characteristic *dl* phenotype. Figure 1 also shows that the proximal breakpoint of $In(2L)dl^H$ maps just distally to 37C1,2, which contains the gene for dopa decarboxylase (*Ddc*). The *Ddc* gene and a surrounding 100-kilobase (kb) region have been cloned by Hirsch and Davidson[6]. We were able to 'jump' into the *dl* region by 'walking' from *Ddc* to the $In(2L)dl^H$ breakpoint (for an explanation of walking see ref. 7).

Recombinants containing the rearranged DNA of the inversion chromosome were isolated and characterized (see Fig. 2 legend). As expected, these recombinants hybridized *in situ* to two distinct sites, 36C and 37B-C, in wild-type polytene chromosomes; this is shown for the recombinant iH-6 in Fig. 2*a*. A restriction fragment from iH-6, containing only 36C DNA sequences, was then used to isolate a wild-type genomic recombinant from the *dl* region. Starting from this recombinant, we isolated a 75-kb segment surrounding the dl^H breakpoint (Fig. 3). This 75-kb DNA segment was oriented with respect to the left arm of chromosome 2 by *in situ* hybridization to the $In(2L)dl^H$ chromosome. We also localized the distal edge of the deficiency *Df(2L)TW119* (which uncovers the *dorsal* gene) in the overlapping sequences of recombinants D15 and D31 (see *b* in Fig. 3). These findings indicate that the odd-numbered recombinants map to the distal side of the dl^H breakpoint towards the telomere, but the even-numbered recombinants are proximal or towards the centromere. Moreover, these findings suggest that the *dl* locus is situated within or proximal to phage D15.

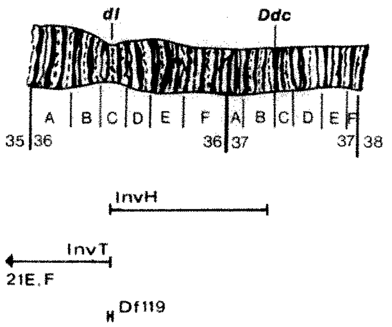

Fig. 1 Chromosome rearrangements on chromosome 2L in the *dorsal* region. *dl*, *dorsal*; *Ddc*, *dopa decarboxylase*; In H, $In(2L)dl^H$; In T, $In(2L)dl^T$; Df119, *Df(2L)TW119*.

As dl^H and dl^T both inactivate the *dl* gene, the localization of the respective breakpoints in the 75-kb walk should permit the identification of DNA sequences essential for normal *dorsal* gene function. Our cloning strategy suggests that the dl^H breakpoint must be located within the recombinant D1. To identify the dl^T breakpoint, we used recombinants from the 75-kb walk to probe genomic blots of dl^T DNA. These experiments showed that the dl^T breakpoint was also contained within the recombinant D1. To map each breakpoint more precisely, we used specific restriction fragments from the phage D1 (Fig. 4*a*) as probes to compare the DNA sequence organization of the two inversions with that of the wild-type parental chromosome. Figure 2*b* shows that both inversion breakpoints map within a small 2.3-kb *Hin*dIII–*Sst*I restriction fragment near the centre of phage D1. Moreover, the breakpoints are localized at different sites within this restriction fragment. These findings indicate that this small DNA segment contains sequences essential for *dl* gene function.

To identify the *dorsal* transcription unit, as well as other genes in the 75-kb region, we probed Northern blots of total and poly(A)$^+$ embryonic RNA with the recombinant phage that spans the *dorsal* region; only three transcription units were detected. Two of these were found to be located in the *Drosophila* DNA segments of phages D31 and D51 and were mapped further using isolated restriction fragments. As indicated in Fig. 3, both transcription units (*c*) are localized distal to the DNA sequences deleted in *Df(2L)TW119*, and hence are unlikely to represent the *dorsal* gene.

The third transcription unit, which encodes a mature poly(A)$^+$ RNA of 2.8 kb (Fig. 4*b*), mapped to the phage D1. We defined the coding region for this 2.8-kb RNA more precisely by probing Northern blots with restriction fragments isolated from D1 and adjacent recombinants. As indicated in Fig. 4*a*, fragments 4–8 were found to contain sequences complementary to the 2.8-kb RNA. Together these fragments span a DNA segment of ~8 kb, which is more than twice the size of the mature RNA, and hence we would expect this transcription unit to contain intervening sequences. As the sequences encoding the 2.8-kb RNA include the *Hin*dIII–*Sst*I fragment (fragment 5 of Fig. 4*a*) which contains the dl^H and dl^T breakpoints, we conclude that this 8-kb transcription unit represents the *dorsal* gene.

To determine the direction of transcription of the *dl* gene, a *Hin*dIII–*Sal*I restriction fragment (fragment 8, Fig. 4*a*) from the proximal end of the transcription unit was subcloned in opposite orientations into the M13 single-strand vectors, mp8 and mp9. The resulting recombinant mp8-8 has the *Sal*I restriction site at the 5′ end of the insert and the *Hin*dIII site at the 3′ end. Conversely, mp9-8 has a 5′ *Hin*dIII and 3′ *Sal*I site. Radioactively-labelled complementary strand DNA was prepared from each recombinant and hybridized to a Northern blot of early embryo poly(A)$^+$ RNA. Figure 4*b* shows that only the complementary strand synthesized from the recombinant mp8-8 hybridized to the RNA. This result shows that the 5′ end of the *dorsal* transcription unit is on the proximal side of the locus, close to the *Sal*I restriction site, while the 3′ end is on the distal side (see Fig. 4*a*).

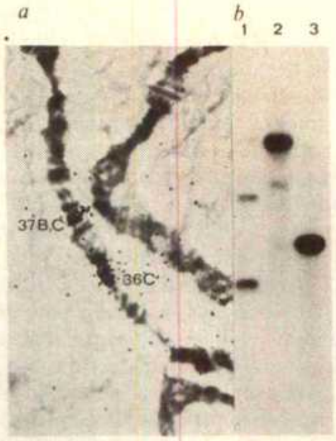

Fig. 2 *a*, *In situ* hybridization of the recombinant phage iH-6 (containing the dl^H breakpoint) to wild-type chromosomes. *b*, Inversion breakpoints in the *dorsal* gene. Lane 1, $In(2L)dl^T/Df(2L)TW119$ DNA. Lane 2, $In(2L)dl^H/Df(2L)TW119$ DNA. Lane 3, DNA of the parental chromosome. The DNAs were digested with *Hin*dIII. The Southern blot was hybridized with fragment 5 (see Fig. 4*a*).
